GLAUBERS SALT—200 bbl., Hamburg, Order

GLYCERINE—125 dr, Buenos Aires, Thornett & Fehr; 305 csk., Marseilles, Order, 28 dr., London, Marx & Rawolleo

GUMS—1,250 bg. arabic, Sudan, Order; 150 bg arabic, Sudan, Anglo-Egyptian Bank, 64 bg. damar, Singapore, Paterson, Boardman & Knapp; 128 bg damar and 50 bg copal, Singapore, L. C Gillespie & Sons, 256 pkg damar and 64 pkg. copal, Singapore, Order; 20 bg copal, Manila, Order, 38 cs. tragacanth, London, Thurston & Braidich; 182 bg. copal, Singapore, Baring Bros & Co.; 172 bg copal, Singapore, Irving Bank-Col. Trust Co; 500 pkg. damar, Singapore, Order; 23 bg. sandrac, London, G. H. Lincks; 259 pkg kauri, Auckland, Brown Bros. & Co., 119 cs. do., Auckland, Chemical Nat'l Bank; 503 cs do., Auckland, J D. Lewis, 339 cs. do., Auckland, Irving Bank-Col. Trust Co., 75 cs do., Auckland, Guaranty Trust Co., 125 cs do, Auckland, L. C. Gillespie & Sons, 637 sks do., Auckland, Am Foreign Banking Corp, 657 pkg. do., Auckland, Order 300 bg yacca, Adelaide, W. Schall & Co., 100 cs damar, Batavia, Bank of America, 1,000 cs damar, Batavia, Nat'l City Bank, 200 cs. damar, Batavia, Central Union Trust Co., 210 bg damar, Singapore, Baring Bros. & Co.; 385 bg damar, Singapore, Kidder, Peabody & Co., 70 bg do, Singapore, L. C Gillespie & Son; 50 bg copal, Singapore, Order, 462 bg. copal, Singapore, Baring Bros. & Co, 288 bg copal, Singapore, France, Campbell & Darling, 243 bg. copal, Singapore, Order.

HYDROGEN PEROXIDE—64 cs, Antwerp, Order

IODINE—138 bbl., Iquique, Nash, Watjen & Bangs

IRON OXIDE—77 csk., Liverpool, Reichard-Coulston, Inc, 10 csk., Liverpool, J H Rhodes & Co, 72 csk., Liverpool, E M & F. Waldo.

IRON SULPHATE—100 bbl, Antwerp, Order.

IRON SULPHIDE—44 bbl., Antwerp, Truempy, Faesy & Besthoff.

LEAD ARSENATE—451 csk, Hamburg, Order

LITHOPONE—1,500 csk, Antwerp, B. Moore & Co., 80 csk., Antwerp, E. M. & F Waldo.

MAGNESITE—8,400 bg, Madras, Order; 83 csk. calcined, Rotterdam, Order; 105 csk., Rotterdam, Speiden, Whitfield Co.; 1,085 pkg., Rotterdam, Innis, Speiden & Co, 1,250 bg. and 152 bbl calcined, Rotterdam, Innis, Speiden & Co.

MAGNESIUM—72 bbl. chloride, Hamburg, Speiden, Whitfield & Co.

MANGROVE BARK—4,000 pkg, Singapore, Order.

MENTHOL—75 cs., Kobe, S W. Bridges & Co, 35 cs, Kobe, F A. Cundill & Co, 25 cs., Kobe, Stanley, Jordan & Co.

NAPHTHALENE—285 pkg., Rotterdam, Lunham & Moore; 250 bg., Hamburg, White Tar Co.; 616 bg, Hamburg, R. W. Greef & Co.; 441 bg., Hamburg, Calco Chem Co., 300 bg., Rotterdam, W C. Jordan & Bros; 3,443 bg., Rotterdam, Order

NUX VOMICA—341 bg., Cocanada, Order.

OCHER—125 csk., Marseilles, J. L. Smith & Co; 90 csk., Marseilles, F. B. Vandegrift & Co.; 290 csk., Marseilles, Am. Exchange Nat'l Bank; 24 bbl., Marseilles, Osborn & Co.

OILS—Cod—300 csk., St. Johns, National Oil Products Co.; 330 csk., St. Johns, R Badcock & Co.; 260 csk., St. Johns, Bowring & Co.; 200 csk., Bergen, Fidelity Union Trust Co. **Castor**—140 bbl., Antwerp, Order. **China Wood**—59 csk., Rotterdam, Order; 25 dr., London, A. A. Stillwell & Co; 760 tons (bulk), Hankow, Balfour, Williamson & Co.; 1,557,366 lb. in bulk, Hong Kong, Mitsui & Co. **Coconut**—107 pipes, Cochin, Order; 875 tons (bulk) Manila, Spencer Kellogg & Sons. **Linseed**—100 bbl, London, Order; 581 bbl., Rotterdam, Nat'l Lead Co.; 286 bbl., Rotterdam, Smith, Weihmann Oil Co.; 145 bbl., Rotterdam, Lockwood Co.; 574 bbl, Rotterdam, W. Benkert Co.; 143 bbl., Rotterdam, Meteor Products Co.; 171 bbl., Rotterdam, Order; 598 bbl., London, W. R. Grace & Co; 599 bbl., London, Balfour, Williamson & Co. **Olive Oil Foots**—100 bbl., Seville, Nat'l City Bank; 145 csk., Leghorn, Am. Co. for Int'l Comm.; 100 bbl., Naples, F. Boehm, Ltd.; 400 bbl., Naples, Order. **Palm**—201 csk., Rotterdam, African & Eastern Trading Co.; 100 csk., Liverpool, Fourth St., Nat'l Bank; 306 csk., Liverpool, D. Bacon; 294 csk., Liverpool, Niger Co., 110 csk., Liverpool, Order; 128 csk., Hamburg, African & Eastern Trading Corp.; 258 csk., Hamburg, Order; 79 bbl., Belawan Deli, Nat'l City Bank. **Palm Kernel**—59 csk., Liverpool, Niger Co. **Perilla**—400 bbl., Darien, Balfour, Williamson & Co, 100 bbl., Kobe, Mitsui & Co.; 150 bbl., Kobe, Bank of N. Y. **Sesame**—291 bbl., Rotterdam, Nat'l City Bank.

OIL SEEDS—Castor—42,973 bg., Cocanada, Order; 2,296 bg., Para, Central Union Trust Co; 1,782 bg., Santos, Bank of N. Y & Trust Co. **Linseed**—69,018 bg., Buenos Aires, Order; 8,700 bg., Rosario, Order, 26,764 bg., Rosario, L. Dreyfus & Co.; 16,609 bg., Buenos Aires, Order; 124,944 bg., Buenos Aires, Order; 8,111 tons, Buenos Aires; L. Dreyfus & Co.; 17,451 bg., Rosario, Order; 6,127 tons, Rosario, Spencer Kellogg & Sons.

PITCH—12 bbl., Liverpool, Order.

PYRIDINE—10 dr., Rotterdam, P. E Falkingham; 5 dr do., Rotterdam, Meteor Products Co.; 24 dr., Rotterdam, Lunham & Moore.

POTASSIUM SALTS—100 dr. permanganate, Rotterdam, J. D. Lewis; 2,000 bg. muriate and 50 bbl. sulphate, Bremen, A. Vogel; 88 csk. nitrate, E. Suter & Co.; 10 dr. permanganate, Hamburg, Equitable Trust Co., 648 dr. caustic, Hamburg, A. Klipstein & Co; 29 csk. salts, Hamburg, A Klipstein & Co.; 93 dr caustic, Hamburg, Order; 43 csk. carbonate, Hamburg, Order; 1,025 pkg. cholrate, Marseilles, Asia Banking Corp.; 250 bbl. chlorate, Marseilles, Order, 100 dr. perchlorate, Marseilles, Order; 49 csk. prussiate, Liverpool, Order; 100 dr permanganate, Hamburg, Order; 4,500 bbl. chlorate, Hamburg, Order, 30 csk. metabisulphite, Hamburg, Order; 3,000 bg. muriate and 3,000 bg. sulphate, Hamburg, Order; 2,250 bg. muriate, Antwerp, Soc Comm. des Potasses de'Alsace, 1,250 csk. chlorate, Antwerp, Order, 225 csk do., Marseilles, Order.

QUICKSILVER—60 fl., Vera Cruz, Poillon & Poirier; 1,000 fl., Alicante, Haas Bros, 50 fl, Genoa, Order.

QUEBRACHO—25,053 bg., Buenos Aires, Tannin Corp.

SHELLAC—590 cs., Hangkok, Order, 300 bg., London, Order; 29 cs., Hamburg, A. Murphy & Co.; 25 bg, Hamburg, Irving Bank-Col. Trust Co.

SODIUM SALTS—7,503 bg. nitrate, Iquique, Wessel, Duval & Co.; 10,355 bg, Iquique, E I du Pont de Nemours & Co.; 93 bbl., phosphate, Antwerp, A. Klipstein & Co.; 62 dr., sulphite Hamburg, Order; 150 cs., chlorate, Genoa, C. W. Campbell; 12 csk., prussiate, Liverpool, Order; 200 csk. hyposulphite, Hamburg, Order; 160 bg. silicate, Hamburg, Order; 216 csk. nitrite, Brevik, Order, 4,105 bg. synthetic nitrate, Brevik, Order; 7,815 bg. nitrate, Antofagasta, W R. Grace & Co.; 9,851 bg. nitrate, Iquique, W. R Grace & Co.

SULPHUR—15 csk. refined, Liverpool, McKesson & Robbins; 6 csk. do., Liverpool, Mallinckrodt Chem. Works; 40 cs. refined, Hamburg, Order.

SUMAC—1,050 bg., Palermo, Nat'l City Bank, 910 bg., Palermo, Order.

TALLOW—147 csk., Buenos Aires, Bank of the Manhattan Co; 278 tc., Montevideo, Battery Park Nat'l Bank; 161 csk., Buenos Aires, Swift & Co.; 152 pkg, Montevideo, Swift & Co.

TARTAR—276 bg., Seville, Order; 220 bg., Marseilles, C. Pfizer & Co.; 427 bg., Marseilles, Tartar Chem. Co.; 306 bg., Alicante, Tarter Chem. Co.

THORIUM NITRATE—50 cs, Hamburg, American, Kruger & Toll Corp.

TUMERIC—507 bg, Cochin, Order: 29 bg, Aleppey, Darragh, Small & Co.

VEGETABLE TALLOW—500 pkg., Hankow, Am Linseed Co.

WAXES—87 bg bees, Antwerp, Elbert & Co.; 222 pkg. carnauba, Ceara, Lazard Freres; 222 pkg do. Ceara, Nat'l Park Bank; 800 bg paraffine, London, Asiatic Petroleum Co.; 283 bg. carnauba, Para, Int'l Acceptance Bank; 177 bg. do, Para, Lazard Freres; 967 bg do, Para, Nat'l City Bank; 167 bg do, Para, Strohmeyer & Arpe; 910 bg do, Para, Order.

WHITING—2,000 bg, Antwerp, Brooklyn Trust Co.

ZINC CHORIDE—138 csk, Hamburg, Order 17 bbl. Hamburg, Order.

ZINC OXIDE—100 csk, Rotterdam, E. M. & F. Waldo.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 38	
Acetone, drums	lb.	.25 -	.25½
Acid, acetic, 28%, bbl.	100 lb.	3 38 -	3 50
Acetic, 56%, bbl.	100 lb.	6 75 -	7 00
Glacial, 99½%, bbl.	100 lb.	12 00 -	12.50
Boric, bbl.	lb	.10½-	
Citric, kegs	lb.	.49 -	.52
Formic, 85%	lb.	.14 -	.16
Gallic, tech.	lb	.45 -	.50
Hydrofluoric, 52%, carboys	lb	.12 -	.12½
Lactic, 44%, tech., light, bbl.	lb	.11½-	.12
22% tech, light, bbl.	lb	.05½-	.06
Muriatic, 18° tanks	100 lb	.90 -	1 00
Muriatic, 20°, tanks,	100 lb.	1 00 -	1 10
Nitric, 36°, carboys	lb	.04½-	.05
Nitric, 42°, carboys	lb	.06 -	.06½
Oleum, 20%, tanks	ton	18 50 -	19 00
Oxalic, crystals, bbl.	lb.	.13½-	.13¾
Phosphoric, 50%, carboys	lb	.07½-	.08½
Pyrogallic, resublimed	lb	1 50 -	1 60
Sulphuric, 60°, tanks	ton	9 50 -	11 00
Sulphuric, 60°, drums.	ton	13 00 -	14 00
Sulphuric, 66°, tanks	ton	16 00 -	16 50
Sulphuric, 66° drums	ton	20.00 -	21.00
Tannic, U S P, bbl	lb	.65 -	.70
Tannic, tech, bbl	lb	.45 -	.50
Tartaric, imp. crys, bbl	lb	.37 -	
Tartaric, imp, powd, bbl.	lb	.37 -	
Tartaric, domestic, bbl.	lb.	.37½-	
Tungstic, per lb	lb	1.10 -	1.20
Alcohol, butyl, drums, f o b works	lb.	.26 -	.28
Alcohol ethyl (Cologne spirit), bbl.	gal.	4.75 -	4 95
Ethyl, 190 p'f U S P, bbl	gal	4.70 -	
Alcohol, methyl (see Methanol)			
Alcohol, denatured, 190 proof			
No. 1, special bbl	gal	.39 -	.41
No. 1, special, dr	gal	.33 -	.35
No. 1, 188 proof, bbl	gal	.40 -	.42
No 1, 188 proof, dr	gal	.34 -	.36
No 5, 188 proof, bbl	gal	.38 -	.40
No 5, 188 proof, dr	gal.	.32 -	.34
Alum, ammonia, lump, bbl	lb.	.03½-	.03¾
Potash, lump, bbl.	lb	.02¾-	.03¼
Chrome, lump, potash, bbl	lb	.05½-	.05¾
Aluminum sulphate, com., bags	100 lb.	1 50 -	1 65
Iron free bags	lb	.02½-	.02¾
Aqua ammonia, 26°, drums	lb	.06½-	.07¼
Ammonia, anhydrous, cyl	lb	.30 -	.30½
Ammonium carbonate, powd casks, imported	lb	.09½-	.10
Ammonium carbonate, powd domestic, bbl	lb	.13 -	.14
Ammonium nitrate, tech., casks	lb.	.10 -	.11
Amyl acetate tech, drums	gal	3 50 -	3 75
Arsenic, white, powd, bbl	lb	.14½-	.15
Arsenic, red, powd, kegs	lb	.14½-	.14¾
Barium carbonate, bbl.	ton	78 00 -	80 00
Barium chloride, bbl.	ton	90.00 -	95.00
Barium dioxide, drums	lb.	.18 -	.18½
Barium nitrate, casks		.08 -	.08½
Barium sulphate, bbl.	lb.	.04 -	.04½
Blanc fixe, dry, bbl.	lb.	.04 -	.04½
Bleaching powder, f.o.b. wks, drums	100 lb.	1.90 -	....
Spot N. Y. drums	100 lb	2.40 -	
Borax, bbl.	lb.	.05½-	.05¾
Bromine, cases	lb	.28 -	.30
Calcium acetate, bags	100 lb	4.00 -	4.05
Calcium arsenate, dr.	lb.	.17 -	.18
Calcium carbide, drums	lb.	.05½-	.05¾
Calcium chloride, fused, drums	ton	22.00 -	23 00
Gran. drums	ton	28.00 -	30 00
Calcium phosphate, mono, bbl.	lb.	.06½-	.07
Camphor, cases	lb.	.86 -	.88
Carbon bisulphide, drums	lb.	.07 -	.07½
Carbon tetrachloride, drums	lb.	.09½-	.10
Chalk, precip.—domestic, light, bbl.	lb.	.04½-	.04¾
Domestic, heavy, bbl.	lb.	.03½-	.03¾
Imported, light, bbl.	lb.	.04½-	.05
Chlorine, liquid, cylinders	lb.	.06 -	.06½
Chloroform, tech., drums	lb.	.35 -	.38
Cobalt oxide, bbl.	lb.	2 10 -	2.25
Copperas, bulk, f.o.b. wks.	ton	19 00 -	20.00
Copper carbonate, bbl.	lb.	.19 -	.20
Copper cyanide, drums	lb.	.47 -	.50
Copper sulphate, crys., bbl.	100 lb.	6 00 -	6.25
Cream of tartar, bbl.	lb.	.25½-	.26½
Epsom salt, dom., tech., bbl.	100 lb.	1 90 -	2.15
Epsom salt, imp., tech., bags	100 lb.	1.00 -	1.15
Epsom salt, U.S.P., dom., bbl.	100 lb.	2.50 -	2.60
Ether, U.S.P., drums	lb.	.13 -	.15
Ethyl acetate, com., 85%, drums	gal.	.80 -	.85
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 -	1.00
Formaldehyde, 40%, bbl	lb.	$0.14½-	$0.15½
Fullers earth—imp, powd., net	ton	30 00 -	32 00
Fusel oil, ref., drums	gal	3 55 -	4.05
Fusel oil, crude, drums	gal	2 50 -	2 60
Glaubers salt, wks, bags.	100 lb	1 20 -	1 40
Glaubers salt, imp, bags	100 lb	.85 -	.95
Glycerine, c p, drums extra	lb	.17¼-	
Glycerine, dynamite, drums	lb	.16½-	.16¾
Glycerine, crude 80%, loose	lb	.11	.11¼
Iodine, resublimed	lb	4 55 -	4 65
Iron oxide, red, casks	lb	.12 -	.18
Lead:			
White, basic carbonate, dry, casks	lb.	.09¼-	.10
White, basic sulphate, casks	lb	.09½-	....
White, in oil, kegs	lb	.12¼-	.14
Red, dry, casks	lb	.11¼-	.12
Red, in oil, kegs	lb	.13½-	.15
Lead acetate, white crys, bbl	lb	.13½-	.14
Brown, broken, casks	lb	.12½-	
Lead arsenate, powd, bbl	lb	.23 -	.24
Lime-Hydrated, bbl.	per ton	16 80 -	17 00
Lime, Lump, bbl	280 lb	3.63 -	3.65
Litharge, comm, casks	lb	.10¾-	.11
Lithophone, bags	lb	.07 -	.07¼
in bbl	lb	.07 -	.07¾
Magnesium carb, tech, bags	lb	.08 -	.08½
Methanol, 95%, bbl	gal.	1.18 -	1 20
Methanol, 97%, bbl	gal	1.20 -	1.22
Nickel salt, double, bbl	lb	.10½-	....
Nickel salts, single, bbl.	lb.	.11½-	
Phosgene		.60 -	.75
Phosphorus, red, cases	lb.	.35 -	.40
Phosphorus, yellow, cases	lb	.30 -	.35
Potassium bichromate, casks	lb.	.11¼-	.11½
Potassium bromide, gran, bbl	lb	.19 -	.20
Potassium carbonate, 80-85%, calcined, casks.	lb.	.06¼-	.07½
Potassium chlorate, powd.	lb	.07½-	.08
Potassium cyanide, drums	lb	.45 -	.50
Potassium, first sorts, cask	lb.	.09	.09½
Potassium hydroxide (caustic potash) drums	lb	.08½-	.09
Potassium iodide, cases	lb.	3 65 -	3 75
Potassium nitrate, bbl.	lb.	.06¼-	.07½
Potassium permanganate, drums	lb.	.20 -	.21
Potassium prussiate, red, casks	lb.	.70 -	.72
Potassium prussiate, yellow, casks	lb	.36½-	.37
Salammoniac, white, gran., casks, imported	lb.	.07 -	.07½
Salammoniac, white, gran, bbl., domestic	lb.	.07¾-	.08
Gray, gran., casks	lb.	.08 -	.09
Salsoda, bbl.	100 lb.	1.20	1 40
Salt cake (bulk)	ton	26 00 -	28.00
Soda ash, light, 58% flat, bags, contract	100 lb.	1 60 -	1.67
Soda ash, light, basis, 48%, bags, contract, f.o.b. wks.	100 lb.	1.20 -	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb.	1.75 -	1.80
Soda ash, dense, bags, contract, basis 48%	100 lb.	1.17½-	1.20
Soda ash, dense, in bags, resale	100 lb.	1 85 -	1 90
Soda, caustic, 76%, solid, drums, f a.s.	100 lb.	3.30 -	3.40
Soda, caustic, basis 60%, wks., contract	100 lb.	2 50 -	2.60
Soda, caustic, ground and flake, contracts	100 lb.	3.80 -	3.90
Soda, caustic, ground and flake, resale	100 lb.	3.72½-	..
Sodium acetate, works, bags	lb.	.05½-	.06¼
Sodium bicarbonate, bbl.	100 lb.	2.00 -	2.50
Sodium bichromate, casks	lb.	.08¼-	.08½
Sodium bisulphate (niter cake)	ton	6.00 -	7.00
Sodium bisulphite, powd., U.S.P., bbl.	lb.	.04¼-	.04½
Sodium chlorate, kegs	lb.	.06¼-	.07
Sodium chloride	long ton	12.00 -	13.00
Sodium cyanide, cases	lb.	.20 -	.23
Sodium fluoride, bbl.	lb.	$0.09½-	$0 10
Sodium hyposulphite, bbl	lb.	.02½-	.03
Sodium nitrite, casks	lb.	.08 -	.08½
Sodium peroxide, powd., cases	lb.	.28 -	.30
Sodium phosphate, dibasic, bbl.	lb.	.03½-	.04
Sodium prussiate, yel. drums	lb	.17½-	.17¾
Sodium silicate (40°, drums)	100 lb.	.80 -	1.25
Sodium silicate (60°, drums)	100 lb.	2.00 -	2.25
Sodium sulphide, fused, 60-62% drums.	lb.	.04½-	.04¾
Sodium sulphite, crys., bbl.	lb	.03½-	.03¾
Strontium nitrate, powd, bbl.	lb	.12½-	.13
Sulphur chloride, yel drums.	lb	.04½-	.05
Sulphur, crude	ton	18.00 -	20.00
At mine, bulk	ton	16 00 -	18.00
Sulphur, flour, bag.	100 lb	2 25 -	2.35
Sulphur, roll, bag	100 lb.	2.00 -	2.10
Sulphur dioxide, liquid, cyl.	lb.	.08 -	.08½
Talc—imported, bags	ton	30 00 -	40.00
Talc—domestic powd, bags.	ton	18 00 -	25.00
Tin bichloride, bbl	lb.	.12½-	.13¾
Tin oxide, bbl	lb.	.50 -	....
Tin crystals, bbl.	lb	.35½-	.36
Zinc carbonate, bags.	lb.	.14 -	.14½
Zinc chloride, gran, bbl.	lb.	.06 -	.07
Zinc cyanide, drums.	lb.	.37 -	.38
Zinc oxide, lead free, bbl.	lb.	.08 -	.08½
5% lead sulphate, bags	lb	.07½-	....
10 to 35 % lead sulphate, bags	lb	.07 -	.....
French, red seal, bags	lb.	.09¼-	.....
French, green seal, bags	lb	.10¼-	.....
French, white seal, bbl	lb	.12 -	.....
Zinc sulphate, bbl.	100 lb	2.50 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl.	lb	$0.65 -	$0.80
Alpha-naphthol, ref, bbl	lb.	.75 -	.90
Alpha-naphthylamine, bbl.	lb.	.35 -	.37
Aniline oil, drums	lb.	.16 -	.16½
Aniline salts, bbl	lb.	.24 -	.25
Anthracene, 80%, drums.	lb.	.75 -	1.00
Anthracene, 80%, imp, drums, duty paid	lb.	.70 -	.75
Anthraquinone, 25%, paste, drums	lb	.70 -	.75
Benzaldehyde U.S.P., carboys	lb	1 40 -	1.45
tech, drums	lb	.75	.80
Benzene, pure, water-white, tanks and drums	gal	.30 -	.32
Benzene, 90%, tanks & drums	gal.	.27 -	.30
Benzene, 90%, drums, resale.	gal.	.30 -	.33
Benzidine base, bbl.	lb	.85 -	.90
Benzidine sulphate, bbl.	lb.	.70 -	.75
Benzoic acid, U.S.P., kegs	lb.	.72 -	.75
Benzoate of soda, U.S.P., bbl.	lb.	.57 -	.65
Benzyl chloride, 95-97%, ref, drums	lb.	.45 -	
Benzyl chloride, tech., drums	lb.	.30 -	.35
Beta-naphthol, subl, bbl.	lb.	.55 -	.60
Beta-naphthol, tech., bbl.	lb.	.22½-	.23
Beta-naphthylamine, tech.	lb.	.80 -	.90
Carbazol, bbl.	lb.	.75 -	.90
Cresol, U S P., drums	lb.	.25 -	.29
Ortho-cresol, drums	lb.	.28 -	.30
Cresylic acid, 97%, resale, drums	gal.	1 30 -	
95-97%, drums, resale	gal.	1.20 -	1.25
Dichlorbenzene, drums	lb.	.07 -	.09
Diethylaniline, drums	lb.	.50 -	.60
Dimethylaniline, drums	lb.	.42 -	.43
Dinitrobenzene, bbl	lb.	.19 -	.20
Dinitroclorbenzene, bbl.	lb.	.22 -	.23
Dinitronaphthalene, bbl.	lb.	.30 -	.32
Dinitrophenol, bbl.	lb.	.35 -	.40
Dinitrotoluene, bbl	lb.	.20 -	.22
Dip oil, 25%, drums	gal.	.25 -	.30
Diphenylamine, bbl.	lb.	.50 -	.52
H-acid, bbl.	lb.	.82 -	.90
Meta-phenylenediamine, bbl.	lb.	1.00 -	1.05
Michlers ketone, bbl.	lb.	3.00 -	3.50
Monochlorbenzene, drums	lb.	.08 -	.10
Monoethylaniline, drums	lb.	.95 -	1.10
Naphthalene, flake, bbl.	lb.	.09 -	.09½
Naphthalene, balls, bbl.	lb.	.09¾-	.10¼
Naphthionate of soda, bbl.	lb.	.58 -	.65
Naphthionic acid, crude, bbl.	lb.	.55 -	.60
Nitrobenzene, drums	lb.	.10 -	.12
Nitro-naphthalene, bbl.	lb.	.30 -	.35
Nitro-toluene, drums	lb.	.15 -	.17
N-W acid, bbl.	lb.	1 25 -	1.30
Ortho-amidophenol, kegs	lb.	2.30 -	2.35
Ortho-dichlorbenzene, drums	lb.	.17 -	.20
Ortho-nitrophenol, bbl.	lb.	.90 -	.92
Ortho-nitrotoluene, drums	lb.	.10 -	.12
Ortho-toluidine, bbl.	lb.	.14 -	.15
Para-amidophenol, base, kegs	lb.	1.20 -	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 -	1.35
Para-dichlorbenzene, bbl.	lb.	.17 -	.20
Paranitraniline, bbl.	lb.	.74 -	.75
Para-nitrotoluene, bbl.	lb.	.60 -	.65
Para-phenylenediamine, bbl.	lb.	1.45 -	1.50
Para-toluidine, bbl	lb.	.95 -	.98
Phthalic anhydride, bbl.	lb.	.35 -	.38
Phenol, U.S.P., drums	lb.	.55 -	.57
Picric acid, bbl.	lb.	.20 -	.22
Pyridine, dom., drums	gal.	nominal	

Pyridine, imp., drums	gal.	$2.50 –	$2.75
Resorcinol, tech., kegs	lb.	1.40 –	1.50
Resorcinol, pure, kegs	lb.	2.00 –	2.25
R-salt, bbl.	lb.	.55 –	.60
Salicylic acid, tech., bbl.	lb.	.47 –	.48
Salicylic acid, U.S.P., bbl.	lb.	.50 –	.52
Solvent naphtha, water-white, drums	gal.	.37 –	.40
Crude, drums	gal.	.24 –	
Sulphanilic acid, crude, bbl.	lb.	.18	.20
Thiocarbanilide, kegs	lb.	.35 –	.38
Toluidine, kegs	lb.	1.20 –	1.30
Toluidine, mixed, kegs	lb.	.30 –	.35
Toluene, tank cars	gal.	.30 –	.35
Toluene, drums	gal.	.35 –	.40
Xylidines, drums	lb.	.45 –	.47
Xylene, pure, drums	gal.	.75 –	1.00
Xylene, com., drums	gal.	.37 –	
Xylene, com., tanks	gal.	.32 –	...

Naval Stores

Rosin B-D, bbl.	280 lb.		$6.10 –	
Rosin E-I, bbl.	280 lb.		6.15 –	
Rosin K-N, bbl.	280 lb.		6.20	
Rosin W.G.-W.W., bbl.	280 lb.		6.50 –	7.50
Wood rosin, bbl.	280 lb.		6.00	6.10
Turpentine, spirits of, bbl.		gal.	1.08 –	
Wood, steam dist., bbl.		gal.	1.04	
Wood, dest. dist., bbl.		gal.	.90	
Pine tar pitch, bbl.	200 lb.			6.00
Tar, kiln burned, bbl.	500 lb.		–	13.00
Retort tar, bbl.	500 lb.			12.00
Rosin oil, first run, bbl.		gal.	.45	
Rosin oil, second run, bbl.		gal.	.48	
Rosin oil, third run, bbl.		gal.	.52	
Pine oil, steam dist.		gal.	.80	
Pine oil, pure, dest. dist.		gal.	.75 –	
Pine tar oil, ref.		gal.	.48 –	
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla.		gal.	.32 –	.32½
Pine tar oil, double ref., bbl.		gal.	–	.75
Pine tar, ref., thin, bbl.		gal.	–	.25
Pinewood creosote, ref., bbl.		gal.		.52

Animal Oils and Fats

Degras, bbl.	lb.	$0.03½ –	$0.04½
Grease, yellow, bbl.	lb.	.07¼ –	.07¾
Lard oil, Extra No. 1, bbl.	gal.	.90	.92
Neatsfoot oil, 20 deg., bbl.	gal.	1.30	
No. 1, bbl.	gal.	.92	.94
Oleo Stearine		.10½	
Red oil, distilled, d.p. bbl.	lb.	.11	.11¼
Saponified, bbl.	lb.	.11	.11¼
Tallow, extra, loose	lb.	.08	
Tallow oil, acidless, bbl.	gal.	.94	.96

Vegetable Oils

Castor oil, No. 3, bbl.	lb.	$0.14	
Castor oil, No. 1, bbl.	lb.	.14½	
Chinawood oil, bbl.	lb.	.34 –	.35
Coconut oil, Ceylon, bbl.	lb.	.10 –	.10½
Ceylon, tank, N.Y.	lb.	.08½ –	.09
Coconut oil, Cochin, bbl.	lb.	.10½ –	.10½
Corn oil, crude, bbl.	lb.	.12½ –	
Crude, tanks, (f.o.b. mill)	lb.	.10 –	
Cottonseed oil, crude (f.o.b. mill), tanks	lb.	.09¼	
Summer yellow, bbl.	lb.	.12 –	
Winter yellow, bbl.	lb.	.13½ –	.13½
Linseed oil, raw, car lots, bbl.	gal.	1.14 –	
Raw, tank cars (dom.)	gal.	1.09 –	
Boiled, cars, bbl. (dom.)	gal.	1.16 –	
Olive oil, denatured, bbl.	gal.	1.10 –	
Sulphur, (foots) bbl.	lb.	.09½ –	.09½
Palm, Lagos, casks	lb.	.07½ –	.08
Niger casks	lb.	.07½	.07½
Palm kernel, bbl.	lb.	.09½ –	
Peanut oil, crude, tanks (mill)	lb.	.13½ –	
Peanut oil, refined, bbl.	lb.	.17 –	
Perilla, bbl.	lb.	.16½ –	.16½
Rapeseed oil, refined, bbl.	gal.	.84 –	.85
Rapeseed oil, blown, bbl.	gal.	.90 –	.91
Sesame, bbl.	lb.	.11½ –	.12½
Soya bean (Manchurian), bbl.	lb.	.13 –	
Tank, f.o.b. Pacific coast	lb.	.10½	.10½
Tank, (f.o.b. N.Y.)	lb.	.10½ –	.10½

Fish Oils

Cod, Newfoundland, bbl.	gal.	$0.70	$0.72
Menhaden, light pressed, bbl.	gal.	.76 –	
White bleached, bbl.	gal.	.78 –	
Blown, bbl.	gal.	.82 –	
Crude, tanks (f.o.b. factory)	gal.	.50	
Whale No. 1 crude, tanks, coast	lb.	.07½ –	.08
Winter, natural, bbl.	gal.	.76 –	.78
Winter, bleached, bbl.	gal.	.79 –	.80

Oil Cake and Meal

Coconut cake, bags	ton	$32.00 –	...
Copra, sun dried, bags, (c.i.f.)	lb.	.05½ –	
Sun dried Pacific coast	lb.	.05½ –	
Cottonseed meal, f.o.b. mills	ton	38.00 –	
Linseed cake, bags	ton	36.00 –	
Linseed meal, bags	ton	38.50 –	

Dye & Tanning Materials

Albumen, blood, bbl.	lb.	$0.45 –	$0.50
Albumen, egg, tech., kegs	lb.	.80 –	.85
Cochineal, bags	lb.	.35 –	.36
Cutch, Borneo, bales	lb.	.04½ –	.05
Cutch, Rangoon, bales	lb.	.13 –	.13½
Dextrine, corn, bags	100 lb.	3.64 –	3.69
Dextrine, gum, bags	100 lb.	3.99 –	4.09
Divi-divi, bags	ton	38.00 –	39.00
Fustic, sticks	ton	30.00 –	35.00
Fustic, chips, bags	lb.	.04 –	.05
Logwood, sticks	ton	28.00 –	30.00
Logwood, chips, bags	lb.	.02½ –	.03½
Sumac, leaves, Sicily, bags	ton	70.00 –	72.00
Sumac, ground, bags	ton	$65.00 –	$67.00
Sumac, domestic, bags	ton	40.00 –	42.00
Starch, corn, bags	100 lb.	2.97 –	3.07
Tapioca flour, bags	lb.	.05½ –	.06½

Extracts

Archil, conc., bbl.	lb.	$0.17 –	$0.18
Chestnut, 25%, tannin, tanks	lb.	.02 –	.03
Divi-divi, 25%, tannin, bbl.	lb.	.04 –	.05
Fustic, crystals, bbl.	lb.	.20 –	.22
Fustic, liquid, 42°, bbl.	lb.	.08 –	.09
Gambier, liq., 25%, tannin, bbl.	lb.	.08 –	.09
Hematine crys., bbl.	lb.	.14 –	.18
Hemlock, 25%, tannin, bbl.	lb.	.04 –	.05
Hypernic, solid, drums	lb.	.24 –	.26
Hypernic, liquid, 51°, bbl.	lb.	.14 –	.17
Logwood, crys., bbl.	lb.	.19 –	.20
Logwood, liq., 51°, bbl.	lb.	.09 –	.10
Quebracho, solid, 65%, tannin, bbl.	lb.	.04½ –	.05
Sumac, dom., 51°, bbl.	lb.	.06½ –	.07

Dry Colors

Blacks, Carbongas, bags, f.o.b. works	lb.	$0.16 –	$0.18
Lampblack, bbl.	lb.	.12 –	.40
Mineral, bulk	ton	35.00 –	45.00
Blues, Bronze, bbl.	lb.	.55 –	.60
Prussian, bbl.	lb.	.55 –	.60
Ultramarine, bbl.	lb.	.08 –	.35
Browns, Sienna, Ital., bbl.	lb.	.06 –	.14
Sienna, Domestic, bbl.	lb.	.03½ –	.04
Umber, Turkey, bbl.	lb.	.04 –	.04¼
Greens, Chrome, C.P. Light, bbl.	lb.	.32 –	.34
Chrome, commercial, bbl.	lb.	.12 –	.12½
Paris, bulk	lb.	.30 –	.35
Reds, Carmine No. 40, tins	lb.	4.50 –	4.70
Oxide red, casks	lb.	.10 –	.14
Para toner, kegs	lb.	1.00 –	1.10
Vermilion, English, bbl.	lb.	1.30 –	1.32
Yellow, Chrome, C.P. bbls.	lb.	.20 –	.21
Ocher, French, casks	lb.	.02½ –	.03

Waxes

Bayberry, bbl.	lb.	$0.28 –	$0.30
Beeswax, crude, bags	lb.	.19½ –	.20½
Beeswax, refined, light, bags	lb.	.32 –	.34
Beeswax, pure white, cases	lb.	.40 –	.41
Candelilla, bags	lb.	.23 –	.24
Carnauba, No. 1, bags	lb.	.42 –	.43
No. 2, North Country, bags	lb.	.23 –	.23½
No. 3, North Country, bags	lb.	.19 –	.19½
Japan, cases	lb.	.14½ –	.15
Montan, crude, bags	lb.	.04½ –	.04½
Paraffine, crude, match, 105-110 m.p.	lb.	.04½ –	.04½
Crude, scale 124-126 m.p., bags	lb.	.03 –	.03⅛
Ref., 118-120 m.p., bags	lb.	.03½ –	...
Ref., 125 m.p., bags	lb.	.03½ –	...
Ref., 128-130 m.p., bags	lb.	.04½ –	.04½
Ref., 133-135 m.p., bags	lb.	.05 –	...
Ref., 135-137 m.p., bags	lb.	.05½ –	.05½
Stearic acid, sgle pressed, bags	lb.	.13½ –	...
Double pressed, bags	lb.	.14½ –	...
Triple pressed, bags	lb.	.15½ –	.16

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3.25 –	$3.30
F.a.s. double bags	100 lb.	3.85 –	3.90
Blood, dried, bulk	unit	4.25 –	
Bone, raw, 3 and 50, ground	ton	27.00 –	30.00
Fish scrap, dom., dried, wks.	unit	4.00 –	
Nitrate of soda, bags	100 lb.	2.60 –	2.65
Tankage, high grade, f.o.b. Chicago	unit	3.25 –	3.50
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$4.00 –	$4.50
Tennessee, 78-80%	ton	8.00 –	8.25
Potassium muriate, 80%, bags	ton	34.55 –	
Potassium sulphate, bags basis 90%	ton	43.67 –	
Double manure salt	ton	25.72 —	
Kainit	ton	7.22 —	....

Crude Rubber

Para—Upriver fine	lb.	$0.26½ –	...
Upriver coarse	lb.	.23 –	...
Upriver caucho ball	lb.	.25 –	
Plantation—First latex crepe	lb.	.27½ –	.27½
Ribbed smoked sheets	lb.	.27½ –	.27½
Brown crepe, thin, clean	lb.	.25½ –	...
Amber crepe No. 1	lb.	.26½ –	.26½

Gums

Copal, Congo, amber, bags	lb.	$0.12 –	$0.13
East Indian, bold, bags	lb.	.23 –	.23½
Manila, pale, bags	lb.	.20 –	.20½
Pontianak, No. 1 bags	lb.	.20 –	.20½
Damar, Batavia, cases	lb.	.30 –	.30½
Singapore, No. 1, cases	lb.	.34½ –	.35
Singapore, No. 2, cases	lb.	.24 –	.25
Kauri, No. 1, cases	lb.	.65 –	.67
Ordinary chips, cases	lb.	.18 –	.20
Manjak, Barbados, bags	lb.	.09 –	.09½

Shellac

Shellac, orange fine, bags	lb.	$0.68 –	.....
Orange superfine, bags	lb.	.70 –	.71
A. C. garnet, bags	lb.	nominal	
Bleached, bonedry	lb.	.76 –	.78
Bleached, fresh	lb.	.66 –	.....
T. N., bags	lb.	.64 –	.66

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$500.00 –	....
Asbestos, shingle, f.o.b., Quebec	sh. ton	$65.00 –	$85.00
Asbestos, cement, f.o.b., Quebec	sh. ton	20.00 –	25.00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 –	20.00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13.00 –	15.00
Barytes, floated, f.o.b. St. Louis, bbl.	net ton	28.00 –	....
Barytes, crude f.o.b. mines, bulk	net ton	10.00 –	11.00
Casein, bbl., tech.	lb.	.22½ –	.25
China clay (kaolin) crude, f.o.b. Ga.	net ton	7.00 –	9.00
Washed, f.o.b. Ga.	net ton	8.00 –	9.00
Powd., f.o.b. Ga.	net ton	14.00 –	20.00
Crude f.o.b. Va.	net ton	8.00 –	12.00
Ground, f.o.b. Va.	net ton	14.00 –	20.00
Imp., lump, bulk	net ton	15.00 –	20.00
Imp., powd.	net ton	45.00 –	50.00
Feldspar, No. 1 pottery	long ton	6.00 –	7.00
No. 2 pottery	long ton	4.00 –	5.50
No. 1 soap	long ton	7.00 –	7.50
No. 1 Canadian, f.o.b. mill	long ton	20.00 –	22.00
Graphite, Ceylon, lump, first quality, bbl.	lb.	.06½ –	.
Ceylon, chip, bbl.	lb.	.05¼ –	
High grade amorphous crude	ton	15.00 –	35.00
Gum arabic, amber, sorts, bags	lb.	.15 –	.16
Gum tragacanth, sorts, bags	lb.	.50 –	.60
No. 1, bags	lb.	1.50 –	1.60
Kieselguhr, f.o.b. Cal.	ton	40.00 –	42.00
F.o.b. N.Y.	ton	50.00 –	55.00
Magnesite, crude, f.o.b. Cal.	ton	14.00 –	15.00
Pumice stone, imp., casks	lb.	.03 –	.05½
Dom., lump, bbl.	lb.	.05 –	.05½
Dom., ground, bbl.	lb.	.06 –	.07
Silica, glass sand, f.o.b. Ind.	ton	2.00 –	2.50
Silica, sand blast, f.o.b. Ind.	ton	2.50	5.00
Silica, amorphous, 250-mesh, f.o.b. Ill.	ton	17.00 –	17.50
Silica, bldg. sand, f.o.b. Pa.	ton	2.00 –	2.75
Soapstone, coarse, f.o.b. Vt., bags	ton	7.00 –	8.00
Talc, 200 mesh, f.o.b. Vt., bags	ton	6.50 –	9.00
Talc, 200 mesh, f.o.b. Ga., bags	ton	7.00 –	9.00
Talc, 200 mesh, f.o.b. Los Angeles, bags	ton	16.00 –	20.00

Mineral Oils

Crude, at Wells

Pennsylvania	bbl.	$3.50 – ......
Corning	bbl.	2.00 – ......
Cabell	bbl.	2.16 – ......
Somerset	bbl.	1.95 – ......
Illinois	bbl.	2.07 – ......
Indiana	bbl.	2.08 – ......
Kansas and Oklahoma, 28 deg.	bbl.	1.40 – ......
California, 35 deg. and up	bbl.	1.04 – ......

Gasoline, Etc.

Motor gasoline, steel bbls.	gal.	$0.22½ –	.
Naphtha, V. M. & P. deod., steel bbls.	gal.	.21½ –	....
Kerosene, ref. tank wagon	gal.	.14 –	
Bulk, W. W. export	gal.	.07 –	.
Lubricating oils:			
Cylinder, Penn., dark	gal.	.27 –	.30
Bloomless, 30@31 grav.	gal.	.20 –	.22
Paraffin, pale	gal.	.24 –	.25
Spindle, 200, pale	gal.	.25 –	.26
Petrolatum, amber, bbls.	lb.	.05 –	.05½
Paraffine wax (see waxes)			

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	ton	$45–50
Chrome brick, f.o.b. Eastern shipping points	ton	50–52
Chrome cement, 40-50% Cr_2O_3	ton	23–27
40-45% Cr_2O_3, sacks, f.o.b. Eastern shipping points	ton	23.00
Fireclay brick, 1st. quality, 9-in. shapes, f.o.b. Ky. wks.	1,000	40–46
2nd. quality, 9-in. shapes, f.o.b. wks.	1,000	36–41
Magnesite brick, 9-in. straight (f.o.b. wks.)	ton	65–68
9-in. arches, wedges and keys	ton	80–85
Scraps and splits	ton	85
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48–50
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	48–50
F.o.b. Mt. Union, Pa.	1,000	42–44
Silicon carbide refract. brick, 9-in.	1,000	1,100.00

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N.Y.	ton	$200.00 –	$225.00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11½	.11½
4-6% C	lb.	.12 –	.13
Ferromanganese, 78-82% Mn, Atlantic seabd., duty paid	gr. ton	120.00 –	....
Spiegeleisen, 19-21% Mn.	gr. ton	40.00 –	....
Ferromolybdenum, 50-60% Mo, per lb. Mo	lb.	2.00 –	2.50
Ferrosilicon, 10-15%	gr. ton	48.00 –	50.00
50%	gr. ton	95.00 –	....
75%	gr. ton	150.00 –	160.00

Ferrotungsten, 70-80%, per lb. of W........	lb.	$0.90 - $0.95
Ferro-uranium, 35-50% of U. per lb. of U......	lb.	6.00 -........
Ferrovanadium, 30-40%, per lb. of V........	lb.	3.50 - 3.75

Ores and Semi-finished Products

Bauxite, dom. crushed, dried, f.o.b. shipping points	ton	$6 00 - $9 00
Chrome ore Calif. concentrates, 50% min Cr_2O_3.	ton	22 00 - 23 00
C i f Atlantic seaboard. .	ton	20 50 - 24 00
Coke, fdry , f.o.b ovens .	ton	7.00 - 7 50
Coke, furnace, f o.b ovens ..	ton	6.00 - 6 50
Fluorspar, gravel, f.o.b mines' Illinois.	ton	20.00 - 21 50
Ilmenite, 52% TiO_2 .	lb.	.01½- .01¼
Manganese ore, 50% Mn, c i f Atlantic seaport ..	unit	.33 -. . . . .
Manganese ore, chemical (MnO_2)	ton	75.00 - 80.00
Molybdenite, 85% MoS_2, per lb. MoS_2, N. Y	lb.	.65 - .70
Monazite, per unit of ThO_2, c i f , Atl. seaport	lb	.06 - 08
Pyrites, Span , fines, c i f. Atl seaport ...	unit	.11½- .12
Pyrites, Span., furnace size, c i f Atl. seaport .	unit	.11½- .12
Pyrites, dom fines, f.o.b mines, Ga ..	unit	.12
Rutile, 95% TiO_2	lb.	.12 -........
Tungsten, scheelite, 60% WO_3 and over, per unit WO_3	unit	8.50 - 8 75
Tungsten, wolframite, 60% WO_3 and over, per unit WO_3	unit	8.00 - 8.25
Uranium ore (carnotite) per lb of U_3O_8	lb	3 50 - 3.75
Uranium oxide, 96% per lb U_3O_8	lb	2 25 - 2 50
Vanadium pentoxide, 99% ,	lb.	12 00 - 14 00
Vanadium ore, per lb. V_2O_5	lb.	1 00 - . . . . .
Zircon, washed, iron free, f o b. Pablo, Fla ..	lb.	.04½- .13

Non-Ferrous Materials

	Cents per Lb.
Copper, electrolytic	16¼ 16¾
Aluminum, 98 to 99% .	25 27
Antimony, wholesale, Chinese and Japanese .	7½ - 8½
Nickel, virgin metal	28 30
Nickel, ingot and shot	30-
Monel metal, shot and blocks	32 00
Monel metal, ingots	38 00
Monel metal, sheet bars	45 00
Tin, 5-ton lots, Straits	44 52½
Lead, New York, spot .	7 25
Lead, E St Louis, spot	7 15
Zinc, spot, New York ..	7 27
Zinc, spot, E. St Louis	6 92

Other Metals

Silver (commercial)	oz	$0 66¼
Cadmium	lb	1 00
Bismuth (500 lb lots)..	lb.	2 55
Cobalt .	lb.	2 65@ 2.85
Magnesium, ingots, 99%.....	lb.	1 25

Zinc.........	3 75@ 4 25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes............	$3 29	$3 14
Soft steel bars	3.19	3.04
Soft steel bar shapes..........	3.19	3.04
Soft steel bands.............	3.29	3.19
Plates, ¼ to 1 in. thick..	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

Arkansas

BLATHEVILLE— The Waggoner-Gage Corp. has plans under way for the erection of a new cottonseed oil mill on local site to cost about $250,000, with machinery The plant will consist of a number of buildings and power house.

California

MONOLITH—The Monolith Portland Cement Co. is perfecting plans for enlargements in its plant for considerable increase in capacity It is purposed to increase the output from 3,000 to 6,000 bbl. per day by the close of the year. The initial machinery installation will be designed to advance the capacity to 1,500 bbl daily

LONG BEACH—The Seaboard Refining Co , recently organized, is perfecting plans for the construction of a new oil-refining plant on local site with capacity of about 6,000 bbl daily. It will consist of a number of buildings and is estimated to cost in excess of $750,000, with machinery. The Keck Syndicate, J. L. Keck, president, is interested in the new company

SAN BERNARDINO— The Cajon Lime Products Co , lately formed, has plans in progress for the development of lime deposits and the construction of a plant on property acquired at Camp Cajon, near San Bernardino The initial works will cost about $200,000, including machinery W F Warner, Riverside, Calif , heads the new company

SAN FRANCISCO— The Bass-Hueter Paint Co , 816 Mission St , has awarded a contract to Barrett & Hilp, 918 Harrison St., for the erection of a 4-story plant at Kansas and 24th Sts , estimated to cost $55,000 A. A. Pyle, 918 Harrison St , is architect

COALINGA—The California Asbestos Co has work in progress on a new mill to cost approximately $60,000, including equipment Machinery will be installed at an early date.

LOS ANGELES—The Pan-American Petroleum & Transport Co will build a large storage and distributing plant in connection with its new refinery in the San Pedro district, to provide for a capacity of over 2,000,000 bbl The entire plant will cost close to $5,000,000 E L Doheny is president

Georgia

FORT WENTWORTH —The Savannah Sugar Refining Co., Savannah, is perfecting plans for the rebuilding of the portion of its local plant recently destroyed by fire, with loss approximating $50,000.

Illinois

CHICAGO—The Dryden Rubber Co , 1014 South Kildare Ave , manufacturer of molded and mechanical rubber products, has awarded a general contract to J. H. Clancy & Sons, 189 West Madison St , for the erection of a 1-story plant addition, 69x178 ft., estimated to cost $50,000

CHICAGO—The Commonwealth Varnish Co., 4125 Parker Ave., has commenced the erection of a 1-story building, to be equipped as a laboratory.

OTTAWA—The National Plate Glass Co , General Motors Bldg., Detroit, Mich , has plans in progress for the erection of its proposed new plant addition, consisting of a number of 1-story buildings, and w'll call for bids in the near future. The plant will cost in excess of $5,000,000, with machinery. John Berg is local manager.

CHICAGO—Brenner, Monley & Morris, Inc., care of Fox & Fox, 38 South Dearborn St., architects, is taking bids on a general contract for the erection of a 1-story copper rod mill on Kedzie St., 100x800 ft., estimated to cost $800,000, with machinery. William A. Wood, 50 Church St., New York, is consulting engineer.

Indiana

HAMMOND The Martin Oil & Refining Co , operating at Osborne, near Hammond, plans for the rebuilding of the portion of its plant, destroyed by fire, April 27, with loss estimated at $200,000, including machinery.

MARION—The Upland Flint Glass Works, Inc , manufacturer of hollowware, is perfecting plans for the rebuilding of its local plant, recently destroyed by fire, with loss estimated at $100,000, with machinery. The reconstruction will cost approximately a like amount

ANDERSON The Inter-Continental Tire & Rubber Co , recently organized, has acquired the local plant of the Majestic Tire & Rubber Co , at Cruse and Daly Sts., and will make improvements and extensions in the mill to provide for an initial output of 600 tires per day It is purposed to commence operations at an early date. J. D. Wiggins, president and general manager of the International Rubber Co of America, Inc Anderson, heads the new organization.

Iowa

DUBUQUE— The Ott Rubber Co , Bank & Insurance Bldg , has tentative plans under consideration for the erection of a new 1-story plant with power house, estimated to cost $80,000 J L Ott is president.

Maryland

BALTIMORE The United States Industrial Alcohol Co , Curtis Bay, has plans in progress for the construction of additions to its plant to cost about $750,000, including machinery The work will consist of a large reclaiming plant to be used in connection with the manufacture of potash, with adjoining mill for the production of fertilizers. A new factory will also be constructed for the production of chemicals.

BALTIMORE— The United States Industrial Chemical Co has filed plans for the erection of a 1-story addition, 50x250 ft., at its Fairfield works, to cost about $15,000, exclusive of equipment

BALTIMORE The Wyatt Rubber & Chemical Co , 730 North Eutaw St , recently organized, is planning for the installation of equipment in a local building The company will specialize in the production of rubber cements and kindred products. Charles M Wyatt is president

Massachusetts

EAST BOSTON The Acme White Lead & Color Works, Inc , 266 Border St , has filed plans for the erection of a 1-story plant addition, to replace a portion of its works recently destroyed by fire.

Michigan

HOWLANDSBURG The El-Mora-Lee Paper Co , Kalamazoo, Mich , recently organized with a capital of $600,000, to manufacture kraft and kindred paper products, has tentative plans under consideration for the erection of a new 4-story mill at Howlandsburg, with power house and other mechanical structures, estimated to cost $800,000, with machinery. Irving Hopper is one of the heads of the company, which has established offices at 839 Lake Blvd.

ESCANABA The Universal Magnesite Products Co., has commenced the erection of a new 1-story building, 40x140 ft., for increased production.

Missouri

ELSBERRY —The Crystal Carbonate Lime Co., Louisiana, Mo., will immediately commence rebu'lding the portion of its local plant, recently destroyed by fire, and will install new crushing; mixing and other machinery for the production of commercial fluxing stone.

KANSAS CITY—The American Paper Mfg. Co. will break ground for the construction of a new mill on property recently acquired on Armour Rd., North Kansas City, and will install machinery for an initial daily output of about 30 tons. The plans will cost about $85,000.

New Jersey

TRENTON—The Elite Pottery Co., Enterprise Ave., manufacturer of sanitary earthenware, has awarded a general contract to Harry A. Fasker, Trenton, for the erection of a 1-story addition, to cost about $20,000, exclusive of equipment.

SOUTH MILLVILLE—The Whitall-Tatum Co., manufacturer of druggists' glassware, vials, etc., has preliminary plans under consideration for the rebuilding of the portion of its local plant destroyed by fire, May 3, with loss estimated in excess of $400,000, including machinery Four furnace buildings were seriously damaged, including Plants, 9, 10, 11 and 12.

TRENTON—The Jointless Fire Brick Co., 1130 Clay St., Chicago, Ill, has awarded a contract to James H. Morris & Co., South Broad St, for the erection of the first unit of its new firebrick and refractory plant on New York Ave, Trenton It will be 1 story estimated to cost about $40,000, with equipment

JERSEY CITY—Fire, May 1, destroyed a portion of the plant of the R. T. Claremont Chemical Co., 54 Montgomery St., with loss estimated at about $10,000, including equipment It is planned to rebuild

New York

ROCHESTER Fire April 27, destroyed a portion of the chemical plant at the works of the Eastman Kodak Co, Kodak Park An official estimate of loss has not been made It is planned to rebuild Frank W Lovejoy is general manager

Ohio

BELLAIRE The Bellaire Enamel Co, 18th St, has plans under way for the erection of a new 2-story addition to its plant to cost about $15,000 J V Anderson, Egerter Bldg, Wheeling, W Va, is architect

TORONTO The Board of Trustees will soon commence the installation of a new filtration plant at the municipal waterworks, estimated to cost $125,000

Oklahoma

TULSA The Oklahoma Steel Castings Co has plans nearing completion for enlargements in its plant to double the present output, making a total capacity of close to 30 tons per day E H Cornelius is president

ADA The Athens Glass Works, Inc, Morgantown, W Va, has tentative plans under consideration for the erection of a new branch plant on local site estimated to cost more than $60,000, with equipment

TULSA The Spanish-American Tile Co, recently formed with a capital of $50,000, is perfecting plans for the erection of a local plant for the manufacture of floor and wall tile F W and C J Gallagher, Tulsa, are heads

Pennsylvania

PHILADELPHIA—George D Feidt & Co, 244 North 5th St, manufacturers of chemical products, have plans in preparation for the erection of a new plant at 5th and Buttonwood Sts Clarence E Wunder, 1415 Locust St, is architect

SCOTTDALE—The United States Cast Iron Pipe & Foundry Co is considering the rebuilding of the portion of its local plant destroyed by fire, May 2, with loss estimated at $100,000, including equipment. Headquarters are at 71 Broadway, New York

CLAIRTON—The Pittsburgh Soda Products Co. is arranging for an increase in capital from $100,000 to $200,000, a portion of the proceeds to be utilized for plant expansion J S Nichols is secretary

ARNOLD—The American Window Glass Co, Farmers' Bank Bldg, Pittsburgh, has perfected plans for the rebuilding of the portion of its local plant recently destroyed by fire with loss estimated at $75,000

South Carolina

MARION The Board of Education will install a chemistry and physics laboratory in the proposed new local high school, for which plans will be prepared at an early date

Tennessee

CHATTANOOGA—The Crane Enamelware Co. has commenced the erection of a new plant unit to cost in excess of $150,000, including equipment, and plans to have the initial buildings ready for service at an early date. The company is a subsidiary of the Crane Co., Chicago, Ill.

Texas

STAMFORD—The Rule-Jayton Cotton Oil Co. has acquired the local cottonseed oil mill of the Stamford Oil Co., and plans for additions in the plant for extensive increase in capacity. The crushing output will be increased with additional machinery for a gross of 100 tons per day. C. M Francis is general manager.

FORT WORTH—A new plant for the manufacture of creosote for wood-treating service is being planned by the National Lumber & Creosoting Co, Texarkana, Tex, in connection with a new plant on local site recently acquired. The entire plant is estimated to cost $200,000 John T. Logan is president.

SWEETWATER—The City Commission has authorized the installation of a new filtration plant at the municipal waterworks to cost about $37,000 Work will be placed under way at an early date.

Virginia

STAUNTON The Virginia-Carolina Chemical Co, Richmond is planning for extensions and improvements in its local plant, devoted to the manufacture of fertilizer products, estimated to cost $30,000

HOPEWELL The Hopewell China Co is considering preliminary plans for the rebuilding of its pottery, destroyed by fire, May 1 with loss estimated at $100,000, including machinery.

SOUTH RICHMOND The Economy Concrete Co, recently organized with a capital of $100,000 will commence the immediate erection of a new 1-story plant, 100x160 ft Crushing, grinding, mixing and other machinery will be installed J Scott Parrish is president

Washington

SEATTLE The Superior Portland Cement Co, Seaboard Bldg, has plans for extension in its plant at Concrete, Wash, to include the construction of a hydro electric power plant on Jackman Creek, estimated to cost $175,000

New Companies

CHIN CHIN CHEMICAL CO, 8 South Dearborn St., Chicago, Ill; chemicals and chemical byproducts, $250,000 Incorporators, John A Combs, Percy Kleis and William A Hamilton

HERBST CHEMICAL CORP, New York, N Y, chemicals and chemical byproducts; $20,000 Incorporators M and S. B. Herbst Representative Hyman Bushel, 1482 Broadway.

STAR CHEMICAL CO, Philadelphia, Pa; chemicals and chemical byproducts; $75,000 Incorporators Arthur G McGregor, Omar G Jones and T L Powell Representative Delaware Registration Trust Co, 900 Market St, Wilmington, Del.

SAGINAW RUBBER CO, Saginaw, Mich, rubber products, $10,000 Incorporators: Herbert A. Otto, Robert T Holland and Seward G Andrews, 801 Genesee Ave. The last noted is representative

DIVIDE RIDGE OIL CO, San Francisco, Calif, petroleum products, $500,000. Incorporators: Charles H Holbrook, Jr., William M. Madden and Herman J. Widman Representative. William M. Madden, Crocker Bldg.

QUAKER HILL PAPER CO, New Haven, Conn, paper and pulp products; $50,000. Incorporators: A. W Chambers, H. H. Hitchcock and George P Smith, 185 Church St The last noted is representative.

KERN PRODUCTS CO, Scott and Railroad Sts, Rahway, N. J., organized, chemicals and chemical byproducts. The company is headed by Edgar and Samuel Genstein, 412 West 129th St, New York

GENERAL GLASS CO., Wilmington, Del.; glass products; $1,000,000 Representative: The Colonial Charter Co, Ford Bldg, Wilmington

SHIRLEY OIL CO., INC, Shirley Ill; refined oils, $75,000 Incorporators: Charles W. Hutchinson, John P. Walters and R T Lain, all of Shirley.

BRAENDER RUBBER & TIRE CO., INC., Wallington, N J.; rubber products; $265,000 Incorporators: Benjamin F. Teitelbaum, R E Donahue and David Z Jeselsohn, all of Wallington.

ATLAS PETROLEUM CORP., San Antonio, Tex., petroleum products; $50,000. Incorporators. William and T. R. Levin, and J. E. Mason, all of San Antonio.

AJAX CHEMICAL CO., Wilmington, Del.; chemicals and chemical byproducts; $2,000,000. Representative: Corporation Trust Co. of America, du Pont Bldg., Wilmington.

DEMATTIA INDUSTRIAL ALCOHOLA, INC., New York, N. Y.; industrial alcohol and kindred products; $25,000. Incorporators: M. Demattia, G. H. Phillips and R. M. Walters. Representative: Harold Lee, 36 West 44th St, New York.

DE PREES LABORATORIES, INC., Holland, Mich.; chemical products; $26,000. Incorporators. R. G. Wasey, W. A. and A. J. Diekema, Holland The last noted is representative.

BAY FERTILIZER CO., Tampa Bay, Fla.; fertilizer products; $100,000. Incorporators: S. W. Allen and C. Edmond Worth, both of Tampa Bay.

TITUS CHEMICAL CO., 171 Columbia Ave., North Bergen, N. J., organized; chemicals and chemical byproducts. Thomas A. Titus heads the company

ATLAS PAINT & VARNISH CO., INC., 1923 Blue Island Ave, Chicago, Ill; paints, oils, varnishes, etc, $35,000. Incorporators: John J. Barcal, A. and Frank C. Barta.

RODGERS CHEMICAL CO., Pittsburgh, Pa., organized; chemicals and chemical byproducts Frederick G. Rodgers and J. M. Wellings head the company Representative: Wright & Rundle, Frick Bldg., Pittsburgh.

BESSE SANITARY POWDER MFG. CO, Tulsa, Okla, $5,000, nominal; washing powders, chemical specialties, etc Incorporators: E Besse, E Gray and L. W. Ray, Avant, Okla

FRANK HALVERSEN CO, Jersey City, N. J, paper and pulp products, $100,000 Incorporators Frank Halversen, Allen E Hosking and Frank F. Albietz, 76 Montgomery St Jersey City The last noted is representative

AMERICAN CYANAMID CO Wilmington, Del, calcium carbide and affiliated products, $100,000 Representative Corporation Trust Co of America, du Pont Bldg., Wilmington

WILMINGTON HIDE & TALLOW CO, Wilmington, Ill, greases, oils, etc, $25,000. Incorporators: Aaron Cohen and Samuel G Barnhard, both of Wilmington

SUPERB RUBBER CO OF PENNSYLVANIA, INC, Scottdale, Pa, rubber products; $100,000 Incorporators. W H Grant, James P Strickler and Charles A Miller, Scottdale Representative Corporation Service Co Equitable Bldg, Wilmington, Del

HOWIE GLASS CO, INC, 1260 Grand River Ave, Detroit, Mich.; glass products, $8,000, nominal Incorporators: Joseph L. Hare, Thomas J. Blake and William Howie, 1640 Church St. Detroit The last noted is representative

Opportunities in the Foreign Trade

Parties interested in any of the following opportunities may obtain all available information from the Bureau of Foreign and Domestic Commerce at Washington or from any district office of the bureau The number placed after the opportunity must be given for the purpose of identification.

ARTIFICIAL LEATHER for upholstery, motor car and furniture trades Johannesburg, South Africa. Manufacturers' agency.—6241.

CARBONATE OF POTASH of different grades, in quantity of 20 to 40 tons at a time. Antwerp, Belgium. Purchase—6257.

CHEMICALS, and surgical supplies—Egypt. Manufacturers' agency—6258.

ROSIN, caustic soda, iron and steel products, tin plate, portland cement, paper, and leather. Rio de Janeiro, Brazil. Agency.—6259.

ZINC DUST for Crowe and Merrill metallurgical process Johannesburg. South Africa Agency.—6264

EQUIPMENT for the manufacture of carbon dioxide and cylinders for storing and marketing the gas. Guaynas, Mexico. Purchase.—6267

OIL CAKES, meat scraps, meat cakes, sulphate of ammonia, tankage, etc. Antwerp, Belgium. Purchase.—6280.

TANNING MACHINERY, substantial and modern. Provadia, Bulgaria. Purchase.—6316.

CASEIN, cork stoppers and mineral colors. Prague, Czechoslovakia. Purchase.—6320.

MACHINERY for the extraction of turpentine and byproducts, and implements and supplies for the extraction of the gum from the tree. Guadalajara, Mexico. Purchase—6321.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, May 21, 1923 Number 20

Making the Debtor Pay

SOMETHING of the element of surprise accompanied the announcement on May 16 that French and Belgian troops had occupied four of the largest dye plants of the great German combine. Yet it was but a logical step in France's avowed policy of making a bad debtor pay his just debts. When Berlin on Jan. 13 notified the French Government that because of the Ruhr occupation Germany was suspending all reparation deliveries, she inevitably contracted for just such a counter-move on the part of the allies. The fact that it was a store of dyestuffs worth 4,000,000,000 marks that was confiscated was probably of no more significance to France than would have been an equally valuable stock of coal or iron ore. To the chemical industries of the world, however, this move has a more sinister portent.

The dyes seized by the French will come into immediate competition with products of our chemical industry. Directly this competition may appear as "reparation dyes" to be marketed with entire disregard of their real value; or indirectly, as fabrics dyed at far less than competitive costs. But, fortunately, when viewed from a longer range, the occupation may have a more favorable significance. This disruption to production may be the first step in breaking down the long-standing governmental subsidy and monopolistic organization of the German chemical industry.

Permanent occupation of these plants is, of course, impractical and no one realizes it more than the French. Nor are they laboring under the delusion that there are valuable "dye secrets" that can be carefully dug up and successfully transplanted along the Seine. It is certain, though, that the French will not relinquish control until Germany has made good her default in dye payments.

Labor And Banking

ORGANIZED LABOR has established a number of highly successful banks in recent years, such as that in Cleveland operated by the locomotive engineers. In the past few months this movement has been extended to include New York, the nation's financial capital. These banks are sound and, for the present at least, are well managed. Labor's voyage on the seas of capitalism is attended by a fair breeze and smiling skies.

Whatever changes in weather may occur on this voyage, labor cannot fail, in common with all other travelers, to experience some change, some broadening of outlook, as a result of its trip. Through control of capital, those commanders of labor who decide policy must become familiar with capital's problems. In running a bank successfully, they must put themselves in the place of those who for many years past have been their opponents. The spirit of caution and compromise that so marks the banker may become, at least in part, their spirit. As bankers, the middle path which promotes industrial stability will be more appealing than labor has found it in the past. Co-operation between the elements labor and capital should be easier under these circumstances.

But what this really means for industry is difficult to forecast. It may be that labor eventually hopes so to control capital that labor and capital will be one. Whatever does come of it, it cannot fail to bring some changes, changes worthy of observation and study. And, from our present knowledge of the movement, we believe it will be a beneficial one, deserving of the support of all.

Promoting Mutual Understanding Through Intersectional Meetings

IN ANY organization such as the American Chemical Society with members residing in communities scattered from coast to coast and maintaining viewpoints just as divergent, it is quite natural that there should be occasional misunderstandings. The unfortunate circumstance is that all too frequently, through failure to understand the other fellow's point of view, trivial incidents become magnified until they assume serious proportions. It is not difficult to conceive of a solution. If each member of the society were personally acquainted with every other member, most difficulties could be adjusted quite easily. With a large membership, such an ideal state is, of course, almost impossible to attain, but any activity which leads in that direction is worthy of careful consideration as a means of more closely uniting the profession.

Local section organizations and semi-annual general meetings at strategic points hitherto have provided practically the only means for the members of the American Chemical Society to become better acquainted. These are excellent as far as they go, but they do not satisfy the need completely. Granted that a member knows his entire section, he still has only the local point of view. Very well, let him attend the general meetings and broaden his outlook. A most logical suggestion, but what is the practical outcome? He is bewildered by the sea of strange faces, discouraged at the enormous scale on which operations are conducted and finally for relief turns to friends from his own section. This applies especially to the younger men who are most in need of the benefits to be derived from a widening circle of friends.

What, then, is to be the remedy? Having watched the movement develop, particularly in the Middle West, we unhesitatingly answer "intersectional meetings." The recent gathering at Urbana is typical. In form it

resembled the semi-annual conventions. There were general sessions and four simultaneous group meetings, but there were these essential differences: The group programs were so arranged that all of the papers could be presented adequately and be properly discussed; and proportionately a greater share of time was allotted to social functions. Furthermore with an attendance of 250 or less, the process of getting acquainted with everybody was not a discouraging or an impossible task. Entertainment was furnished by the local members so that there was but little financial strain upon the section acting as host and the total cost of attendance was low enough to attract many younger members who seldom get to the general meetings.

Were the intersectional plan adopted throughout the entire society and a logical rotation of meeting places provided, it would not be long before the members of the sixty-five sections would find a great deal more of common interest and understanding. In our estimation no single activity holds greater possibilities for increasing the solidarity of the American Chemical Society.

A Public Servant Goes Into Industry

ON another page in this issue is the news that one of the government's foremost scientists has resigned to take up an important post in commercial work. Unusual significance attaches to the announcement because of the circumstances as well as the persons involved.

The former chief chemist of the Bureau of Mines is one of the outstanding men of science in America. His work on the rare gases, first as assistant to Sir WILLIAM RAMSAY, and later independently, on radio-activity and the chemical separation of radio-active types of matter, on the atomic weights of krypton and xenon, on the change of thorium emanation to helium, the metallurgy of rare metals, the liquefaction of gases and the properties of matter—these are some of his achievements in pure science. Equally distinguished is his commercial work on the large-scale extraction of radium and, along with others in the bureau, in the practical recovery of helium from natural gas—a process reducing the cost of this pure element from $1,200 a cubic foot to 10 cents and promising a further reduction to 3 or 4 cents.

But like most leaders in research Dr. RICHARD B. MOORE is disposed to bestow greatest credit for these achievements upon those associated with him. Numbered among these is the man who will succeed him at the Bureau of Mines—Dr. SAMUEL C. LIND, a scientist eminently qualified to carry on the work. And, too, it is pleasant to record that the government is thus able to turn to its reserves for men so well fitted to meet such great responsibilities.

Why is it, though, that the Bureau of Mines could not keep this rare talent at work on its own many problems? There has been no ruction or disagreement. Dr. MOORE was singularly happy at his post, and he is not a man of expensive habits. The trouble is that unless a worker in government service has means of his own he cannot hope to provide for old age. In the army and navy provision is made for the retirement of commissioned officers, and even of enlisted men. But civilian salaries, which even before the war were very modest for the competent, have lost considerable of their sustaining power since that time. Reclassification measures have remedied this to some extent, to be sure, but the provisions for retirement are still most niggardly. It is but natural, therefore, that the government should fail to hold the public servant once industry bids for his services.

The Dorr Co. is to be congratulated on this eminent acquisition to its staff. We commiserate Washington on losing Dr. MOORE, but we welcome him as a neighbor with delight and with all good wishes.

The Lunatic Fringe In Science

THERE IS, according to his circulars, a Friend of Man in Pittsburgh, who has sent us through the mails his astro-biochemical chart. From it we learn which of the following twelve salts we should take: *Kali phos.*, *Natrium sulph.*, *Kali mur.*, *Calcara flour.*, *Magnesia phos.*, *Kali sulph.*, *Natrium phos.*, *Calcarea sulph.*, "*Silicea*," *Calcarea phos.*, *Natrium mur.* and *Ferrum phos.* They are, he says,

> . . . birth salts, as the body is most susceptible to them and anyone can use the number covering their (*sic!*) birthday to good advantage, if ill or not, as they are a scientific food and no medicine, and food is always appropriate. In fact that is the reason hunger really comes, as the body craves these tissue salts, and after all the body is composed of nothing else but these twelve salts together with hydrogen, oxygen and carbon, and any one of these elements falling below their standard brings disorder from same.

For a dollar he will send a "trinity" of salts (for it seems all persons need three of them) and he will make an astrological diagnosis of each case and give free advice as to whether we need other salts than those indicated on the chart as our "food."

This is an example of what THEODORE ROOSEVELT used to call "the lunatic fringe" of science. We might paraphrase the old almanac, and say, "Look out for astrology and all sorts of mystery tricks during the next 10 years!"

For science is ceasing to be didactic. It cannot afford to be. The greatest advances made in chemistry within the last 10 years have been in physics, and the greatest advances in biology have been in chemistry. The borders of all branches of science overlap one another more and more, so that it is becoming difficult to specify the domains of research. Science is becoming an immense, articulated Whole, with chemistry and physics and mathematics everywhere. But that day is not yet at hand and in the process of organization now going on, the lunatic fringes are bound to show themselves all over the great fields.

Let's take another view of the same subject. Nearly every leader of science is becoming modest in his assertions. He is scrupulously careful as to his findings, but he will not commit himself as to their ultimate significance. The Greeks made no distinction such as we do between material and spiritual things, and there is a tendency among thoughtful persons today to follow the Greek rather than the later method, by seeking the spiritual things in material things. This does not mean looking for ghosts in a graveyard by the dark of the moon, but it does mean a far more profound, more philosophical and more spiritually minded study of the nature of energy and of the fundamental things in Nature, as we may approach them with greater enlightenment and understanding.

Some time ago we heard an earnest man of science tell of his experiences in investigating so-called "psychic

phenomena"—not to discover the cause of them, but to satisfy himself whether, among supposedly supernatural occurrences, there was anything which could not be explained by sleight-of-hand or coincidence. He was still uncertain as to what conclusion he might ultimately reach, but he gave his experiences for what they were worth. There followed him a man who makes moving pictures, who has no scientific background or study, but he essayed to reply on behalf of science. Aside from his Billingsgate language and his abuse of everyone who is open minded, there was not an idea, a notion or a thought uttered that was anything more than denial. In other words, here was the scientific man engaged in research in what the movie man declared to be rank superstition. The charge of superstition emanated from ignorance, not from scholarship.

We can't declare any more that "the scientists all say" thus and so. Some of them are thinking big thoughts that the man on the street could not grasp if he tried for a thousand years. And like many of his kind such a person grows angry at what he cannot understand. There are, however, an equal number of other men on the street who have the will to believe but not the gift to understand. They flood over in crowds to the waving emblems along the lunatic fringes. They learn with happy credulity from the gentleman we have quoted or from similar authorities that nitrogen, for instance, is not contained in the human body. And their faith will remain unshaken until pale experience teaches them to the contrary that "*Natrium sulph.*" is a food.

Aluminum Sulphate As a Soil Corrective

FROM California comes the note that clay is rapidly displacing fullers earth for the decolorizing of petroleum distillates. Until recently, fullers earth was considered essential for this purpose, being burned and re-used after maximum adsorption had taken place. The clay now employed as a substitute is treated with acid, washed, filtered, dewatered, calcined and reground. By standardizing the various operations and by using a raw product of uniform and suitable composition, it is said to be possible to manufacture a substitute for fullers earth that possesses all the advantages resulting from technical control of operations.

Often the economic success of a new industry depends on the discovery of an outlet for its byproducts. In this particular process it is aluminum sulphate that is the byproduct, and while investigating other possible uses for it inquiries have been made as to its availability as a corrective of certain conditions in soils. In this connection it is interesting to note that FREDERICK C. COVILLE, of the United States Department of Agriculture, describes in a recently issued bulletin of the American Horticultural Society the results of several tests on the acidification of soil. It is recognized that some forms of plant life thrive only in soil that is acid in reaction; the plants of the heath family are examples. Tests were made whereby it was demonstrated that the treatment of an ordinary alkaline soil with aluminum sulphate resulted in a rapid and satisfactory growth.

It is pointed out that aluminum sulphate, in amount up to ½ lb. per square yard, may be applied to soils of the ordinary type to insure an acid reaction, which is necessary for several species of ornamental plants that otherwise are difficult to cultivate. It is well to remember, of course, that these investigations have not yet passed the experimental stage and that the application is necessarily limited by the small area of acid soils required. Further research is doubtless needed to establish definitely the value of aluminum sulphate as a corrective for soils of various types as well as to demonstrate the effect of aluminum compounds on the different forms of plant growth.

Encouragement Of Intuition

AT THE conclusion of his inaugural address delivered in London the newly elected president of the Institution of Mining and Metallurgy, R. GILMAN BROWN, paid us the graceful compliment of saying that he had been encouraged in his views on the subject of responsibility by an editorial on the education of the intuitions that appeared in a recent issue of *Chem. & Met.* He spoke of the need for an ordered imagination—that quality that suggests a new departure from established practice. It was imagination, we are reminded, that rescued the gold industry by the development of a chemical process of extraction—cyanidation; it was imagination that conceived the copper converter, so superficially similar and yet so fundamentally different from the bessemer converter. "Imagination is one of our prime assets; as it plays around standard practice it alone leads us to question whether an established method is, in fact, a perfect conception. Our profession constantly offers us opportunity for such a question; it affords a daily challenge to the imagination, a challenge which we run a personal risk in accepting, but which we may not in honor decline."

WILLIAM JAMES has said that visions usually constitute our most respectable contributions to the world in which we play our part. Mr. BROWN points out that engineers and technologists are better off than philosophers, for they can link together vision and accomplishment. Realization is the test. Uncertainty as to developments makes us cautious and full of fear. A close scrutiny of reasonings and conclusions follows, "thus arraigning the vision before the bar of detailed knowledge and experience, and making it show cause why it should not be committed as a vagrant dream." This caution, we are reminded, is born of experience and disappointment; it tempers the imagination. It should not be confused with timidity, which is inimical to progress.

This discussion suggests that a line of demarcation, indistinct perhaps, may exist between the great designers of our time and what Mr. BROWN calls the rank and file. What of them? To answer this query, the parable of the talents may be used to crystallize the thought that the less gifted one is in honor bound obligated to make the best of his opportunities. The determining factor must be recognized. "Nor is this beyond our powers if we look to our own approval, which is lasting, rather than to the fugacious praise of our fellows."

The application of science to industry is not alone concerned with facts and figures. Speculation and the exercise of the imagination play an important part in laying the foundation needed as a preliminary to achievement. Mr. BROWN approves of "recent developments in our technical journals: the enlistment of editors who are something more than technicians"; and he welcomes their increasing tendency to discuss the non-technical problems that influence profoundly the progress and development of technology.

Charles A. Rose

Following a significant career of 20 years as engineer and executive is appointed general manager of technical activities for the British America Nickel Corporation.

WHEN the British America Nickel Corporation resumes operations this month, Charles A. Rose will be general manager of technical activities. Twenty years of metallurgical experience as engineer and executive stand behind Mr. Rose as he accepts his new post.

As a young graduate from the University of Nebraska, Mr. Rose began his career with the Alder Creek Gold Mining Co., at Leadville, S. D. Here he outgrew his position as chemist within a short time and was promoted to be superintendent of mill operations. He then became chief chemist for the Boston & Colorado Smelting Co. at Denver, and when the next call came to advance he joined the staff of the American Smelting & Refining Co. as metallurgical engineer.

Then Guggenheim Bros. "discovered" Mr. Rose. So it was that in 1911, after rising in 7 years from comparative obscurity to the front rank of his profession, he severed his Colorado connection to become consulting expert for the Guggenheims and for the Braden Copper Co. Here for the past 12 years Mr. Rose has been active in many fields as assistant to the vice-presidents of both companies. As part of his work in this capacity he has been in charge of the experimental plant in the development of the Chile Exploration Co.

Mr. Rose is a man whose personality inspires confidence. His career justifies the impression. Quiet and thoughtful in manner, sparing of superfluous speech, yet cordial in bearing, he has the happy faculty of creating that atmosphere which marks a successful executive. Combining as he does the attributes of leader and of straight-thinking engineer, it is not hard to understand the reason underlying his advancement to his present position.

At Nickelton, Ont., where the activities of the British America Nickel Corporation are centered, Mr. Rose will manage a $20,000,000 corporation. The magnitude of its operations is revealed by its production, which will include close to 10,000 tons of nickel and 5,000 tons of copper annually. Since 1921, due to the dull market, the plants of the concern have lain idle. Even at the present time the venture of resuming operations is regarded in some quarters as precarious; therefore Mr. Rose faces a problem which is difficult, which will require all of his well-rounded experience, but which he is ideally fitted to meet.

An Extension of the Theory of Gas-Absorption Towers*

Abandoning the Arbitrary Assumptions Involved in the Use of the Logarithmic Mean Formula, a General Analysis of Factors Has Been Made and a Fundamental Relationship Between the Variables Evolved—This Relationship Has Been Checked by a Plant Experiment

BY WALLACE B. VAN ARSDEL
Chemical Engineer, The Brown Co., Berlin, N. H

THERE is substantial agreement among workers in the theory of gas-absorption towers, feed-water coolers and the like that the rate of transfer of the solute from one phase to the other is proportional to the area of contact of the phases and to a potential factor, or "driving force." The constant of proportionality, analogous to that operating for heat-flow in double-pipe coolers, has been determined in a few particular cases described in recent literature.

The only theoretical difficulty to the problem lies in the correct formulation and calculation of the potential factor, and on this point there remains a rather serious divergence of opinion. The formula taken in the present paper was first explicitly stated by Donnan and Masson:[1]

$$\text{Potential factor} = (km - n)$$

where m = conc. of solute in gas-phase, g. per liter,
n = conc. of solute in liquid-phase, g. per liter
$k = \dfrac{n}{m}$ at equilibrium ("Henry's law" solubility constant).

Another formulation is the one used by Prof. W. K. Lewis[2] and his co-workers[3,4] at the Massachusetts Institute of Technology:

$$\text{Potential factor} = (P - \alpha x)$$

where P = partial pressure of solute in gas-phase, mm. of Hg,
x = concentration solute in liquid phase, mol-fraction,
$\alpha = \dfrac{P}{x}$ at equilibrium.

The constant α is an *inverse* solubility-function. The two forms of expression for the potential-factor are therefore nearly equivalent, the major difference between them being the occurrence in the latter of an extra factor, α:

$$(P - \alpha x) = \alpha\left(\frac{P}{\alpha} - x\right),$$

equivalent to $\alpha(km - n)$

Very recently some experimental evidence has been presented[4] which indicates clearly that this extra term α should be omitted. If this be done, the remaining difference between the two forms is very small; very careful measurements will be necessary for a judgment between them.

The real difficulty lies in the calculation of the potential factor according to any agreed formulation, since in a counter-current gas-absorption tower, for instance, it varies from point to point. Common practice has been[4,5] to use either the arithmetic or the logarithmic mean of its values at the ends of the transferring system. Now while that is justifiable under certain rather restricted conditions, evidence is here presented which indicates that in many common cases the resulting coefficient is badly in error.

The assumptions on which the logarithmic-mean formula is based are as follows: (*a*) The mass of solute transferred is negligible compared to the total mass of the gas; (*b*) the transfer-coefficient is constant from point to point through the apparatus, and (*c*) the equilibrium solubility-coefficient of the gas, and therefore the temperature of the solvent, is constant from point to point. The arithmetic mean is commonly used when the potentials at the ends are nearly equal, since under those conditions the logarithmic and arithmetic means are nearly the same. Since in practice the above assumptions are by no means always fulfilled, it has seemed to be worth while to investigate the attendant errors and if possible to develop a new type of mean which will fit some of the cases properly excluded by these drastic assumptions.

GENERAL ANALYSIS

Certain quantitative relationships between the variables must be established preliminary to the further analysis. It may easily be shown that:

$$V_G = V_G' \frac{d_1 - M_1}{d - m} \qquad (1)$$

where V_G = rate of gas-flow at any point x in the tower, liters per minute,
V_G' = rate of supply of gas to the tower, liters per minute,
d_1 = density of the pure solute-gas at the temperature and total pressure prevailing at the gas-inlet, grams per liter,
d = density of pure solute-gas at the temperature and pressure prevailing at any point x, grams per liter,
M_1 = concentration of solute-gas in gas entering tower, grams per liter,
m = concentration of solute-gas in the gas at point x, grams per liter.

*Adapted, by the author, from a paper presented at the Richmond, Va., meeting of the American Institute of Chemical Engineers, Dec 7, 1922.

[5]W. B. Van Arsdel, "Theory of Gas Scrubbing Towers," *Chem. & Met.*, vol. 23, pp. 1115-6 (1920).

For the special case of the total change in gas-volume through the tower, a quantity which occurs frequently in subsequent calculations,

$$V_G'' = \frac{d_1 - M_1}{d_2 - M_2} V_G' = \Delta V_G' \qquad (2)$$

where $\Delta = \frac{d_1 - M_1}{d_2 - M_2}$ and V_G'', d_2 and M_2 refer to conditions at the exit point. Formulating a "solute-balance" equation, taking the liquid volume, V_L, as constant, and simplifying,

$$m = \frac{d(f\Delta M_2 + n - N_1)}{f\Delta d_2 + n - N_1} \qquad (3)$$

$$n = f(d_1 - M_1)\left(\frac{m}{d - m} - \frac{M_1}{d_1 - M_1}\right) + N_1 \qquad (4)$$

where $f = \frac{V_G'}{V_L}$, "flow-ratio,"

n = concentration of solute in the liquid at point x, grams per liter,

N_1 = concentration of solute in the liquid entering the tower, grams per liter.

There is abundant evidence that the solute-transfer coefficient, like the heat transfer coefficient in a double-pipe cooler, is a function of the velocities of flow and temperatures of the fluids, and since we have not restricted the problem to uniform velocities and temperatures, the coefficient itself must vary from point to point. Now the most obviously useful data on such coefficients would refer to invariable velocities and temperatures, since a long tower could be considered as a series of short ones, in each of which the appropriate velocity, temperature and coefficient could be used. Such data must therefore be derived from the results of an actual complex run by correlating with the *mean* velocities and temperatures an *average* value of the coefficient. In a differential section,

$$V_L\delta n = k_1 S\phi k_2(km - n)\delta x \qquad (5)$$

where k_1 = a constant characteristic of the packing, sq.ft. of surface per cu.ft. gross volume,

S = cross-section area of tower, sq.ft.,

k_2 = the *average* transfer-coefficient for the tower, grams per minute per sq.ft. per gram-per-liter concentration-deficit,

ϕ = a dimensionless multiplier of k_2, averaging unity for the whole tower, ϕk_2 being the actual coefficient for the section.

All available experimental work[4] (including some of our own not yet published) indicates that as between different runs, and to a rough approximation, k_2 varies

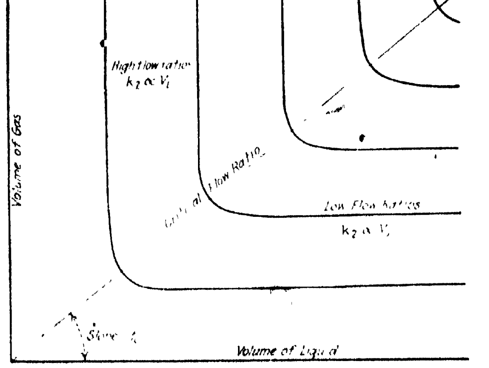

FIG. 1—VARIATION OF TRANSFER-COEFFICIENT WITH CHANGING GAS AND LIQUID FLOW

directly as the gas velocity up to a certain critical flow-ratio, f_c, and directly as the liquid velocity at higher flow-ratios, as suggested diagrammatically by Fig. 1. In addition, k_2 varies inversely as the viscosity of the liquid, η_t, as that is changed by temperature. Moderate change of gas temperature is apparently without effect. Assuming now that for changes in velocity and temperature from point to point in a tower, ϕ varies in the same manner as does k_2 between different runs, four cases may be distinguished by the relation of the actual flow-ratio to the critical flow-ratio, f_c.[9]

	$\frac{U_G}{U_L} > f_c$	$\frac{U_G}{U_L} < f_c$
$\frac{V_G}{V_L} > f_c$	Case (a) $\phi = \frac{U_L \eta_{av}}{U_L \eta_t}$	Case (b) $\phi = \frac{U_L f_c \eta_{av}}{U_G \eta_t}$
$\frac{V_G}{V_L} < f_c$	Case (c) $\phi = \frac{U_G \eta_{av}}{U_L f_c \eta_t}$	Case (d) $\phi = \frac{U_G \eta_{av}}{U_G \eta_t}$

where U_G, U_L and $\eta_{av.}$ are average values of those variables in the given case.

For U_L and η_{av} use the arithmetic mean of the end values. For U_G,

$$U_G = V_G'\left(\frac{1 - \Delta}{\mathrm{Log}_e \frac{d_2 - d_1 + M_1}{\Delta M_1}} + \frac{d_1 - M_1}{d_2}\right)$$

Substituting in equation (5) the value of m from equation (3), and ϕ from this table, simplifying and solving for k_2,

$$(a)\quad k_2 = \frac{V_L}{k_1 h S \eta_{av}} \int_{N_1}^{N_2} \frac{(f\Delta d_2 + n - N_1)\eta_t}{kd(f\Delta M_2 - N_1) + n(kd - f\Delta d_2 + N_1) - n^2}\,\delta n \qquad (6)$$

$$(b)\quad k_2 = \frac{U_G}{k_1 h S f_c \eta_{av}} \int_{N_1}^{N_2} \frac{(f\Delta d_2 + n - N_1)\eta_t}{kd(f\Delta M_2 - N_1) + n(kd - f\Delta d_2 + N_1) - n^2}\,\delta n \qquad (7)$$

$$(c)\quad k_2 = \frac{V_L f_c}{k_1 h S \eta_{av}} \int_{N_1}^{N_2} \frac{d\eta_t}{kd(f\Delta M_2 - N_1) + n(kd - f\Delta d_2 + N_1) - n^2}\,\delta n \qquad (8)$$

$$(d)\quad k_2 = \frac{U_G}{k_1 h S \eta_{av.}} \int_{N_1}^{N_2} \frac{d\eta_t}{kd(f\Delta M_2 - N_1) + n(kd - f\Delta d_2 + N_1) - n^2}\,\delta n \qquad (9)$$

where h = total height of packed portion of tower, feet. Solution of any of these equations depends on the possibility of evaluating k, d and η_t for given values of n; in general, such relations are empirical and the integration will be performed by a step-by-step summation for the range N_1 to N_2.

SOLUTION. CASE 1

When the change in temperature of the liquid may be considered as predominantly due to the heat of solution of the solute, the liquid-temperature and therefore k and η_t become simple functions of n; for evaluation of d, a rough approximation to T (the gas temperature) is sufficient; the change in T may be assumed proportional to the change in t (the liquid temperature). In practice this is a very important and common condition in such absorption towers as those of, say, SO_2 in water; the heat of solution of the SO_2

is almost always far in excess of any accompanying transfer of sensible heat.

It will be noted that the preceding process sidesteps the necessity of determining any space average of the potential factor. Individual values of the potential factor, however, vary inversely as the quantity within the integral in equation (6), (7), (8) or (9), and may be evaluated by comparison with equation (5)

SOLUTION. CASE 2

There is one other case, comparatively unimportant, for which analysis is possible. The restricting assumptions are, (*a*) that transferred sensible heat far exceeds heat developed on absorption of the solute, and (*b*) that changes in the mass and specific heat of the gas are small in comparison with its average mass and specific heat. Summarizing, it may be shown that the liquid temperature then changes from point to point by the exponential law characteristic of heat exchangers, and the solute-concentration by an exactly analogous exponential law; a series of values of $km - n$ may be calculated, and the space-average of these values substituted in the fundamental equation

$$V_L(N_2 - N_1) = k_1hSk_2(km - n)_{av} \qquad (10)$$

REMOVAL AND SATURATION

Two characteristics of tower operation which are nearly always given or required are (*a*) the degree of saturation of the outflowing solution, based on the concentration of gaseous solute entering the tower, and (*b*) the percentage removal of solute from the gas; calling these functions respectively ψ and r,

$$\psi = 100\frac{N_2}{k''M_1} \qquad (11)$$

where k'' = solubility constant for conditions at base of tower.

$$r = 100\left(1 - \Delta\frac{M_2}{M_1}\right) = 100\frac{N_2 - N_1}{fM_1} \qquad (12)$$

For the common case in which $N_1 = 0$,

$$r = \frac{k''}{f}\psi \qquad (13)$$

EXPERIMENTAL CHECK

There is not much experimental material available with which to test the methods of calculation suggested, by actual check of predicted with measured quantities. The following experiment* will serve to show, however, the order of magnitude of the differences from the logarithmic or arithmetic mean methods, in a case which is far from being an extreme test.

A wood-stave tower of 28.25 in. internal diameter was fitted up with nine grids, the bottom six each supporting four layers of 6-in. "spiral brick," the next two grids eight layers, and the top grid four layers. Beneath each grid two spirals of lead pipe were so arranged as to collect fair samples of the gas and solution at that point. Dilute SO_2 gas was blown into the base of the tower and water pumped into the top through a rosette head; the former was measured by a standardized orifice-plate, the latter by the decrease in volume in a storage tank. Gas concentrations at the six lower stations were determined by Orsat apparatus and at the three top ones by Reich apparatus. Solution concentrations were determined by iodine titration.

For this style of packing, $k_1 = 18.06$; the height of packing was 23 ft., cross-section area 4.35 sq.ft.; k_1hS = 1,806.5 sq.ft. Fairly high rates of flow were employed (49.8 cu.ft. of gas per minute per sq.ft. of cross-section and 8.03 gal. of water per minute per sq.ft.) and a low-strength gas, about 6 per cent SO_2 by volume. The resulting data, plotted in Fig. 2, were balanced against one another (individual measurements not being precise enough to allow direct calculation of $km - n$), as follows: A fair curve was drawn through the datum points for n, and then using the "conservation of matter" equation (3), m was calculated from n; this curve agreed reasonably well with the plotted points for m. From the smoothed curve for t and that for m, k was determined on the basis of known solubility data. The curve "$km - n$ measured," in Fig. 3, was the result. The coefficient k_2 was determined as follows by taking δn and $km - n$ in 2-ft. steps:

δn	$km - n$	k_2
0.25	0.40	0.55
0.31	0.48	0.57
0.35	0.56	0.55
0.42	0.64	0.57
0.50	0.71	0.62
0.53	0.76	0.61
0.55	0.80	0.60
0.56	0.815	0.60
0.57	0.81	0.61
0.56	0.79	0.62
0.54	0.75	0.63
0.32	0.71	0.65
	Mean	0.60

Now the temperature change of the water in this run was almost exactly accounted for by the heat of solution of SO_2, and the flow ratio was less than f_c for SO_2 absorption at this temperature, 45.25 as against about 50. Equation (9) above was therefore used, with the following pertinent data:

$G' = 6145$	$M_1 = 0.133$	$t_1 = 23.2$	$d_1 = 2.46$	$k' = 46.3$
$L' = 135.7$	$M_2 = 0.015$	$t_2 = 24.0$	$d_2 = 2.57$	$k'' = 43.1$
$f = 45.25$	$N_1 = 0$	$T_1 = 37$	$\Delta = 0.912$	$\eta_1 = 0.93$ (relative)
$U_G = 5750$	$N_2 = 5.4$	$T_2 = 23$		$\eta_2 = 0.91$ (relative)

Coefficient k_2 is found as 0.594, checking closely with the measured mean k_2 and calculated values of $km - n$ are shown on Fig. 3 to agree well with the curve of measured values.

Calculating the logarithmic mean of $km - n$ at the ends of the tower, k_2 by equation (10) is 0.82; by the arithmetic mean it is 0.785. The reason for the difference from the measured value is obvious from Fig.

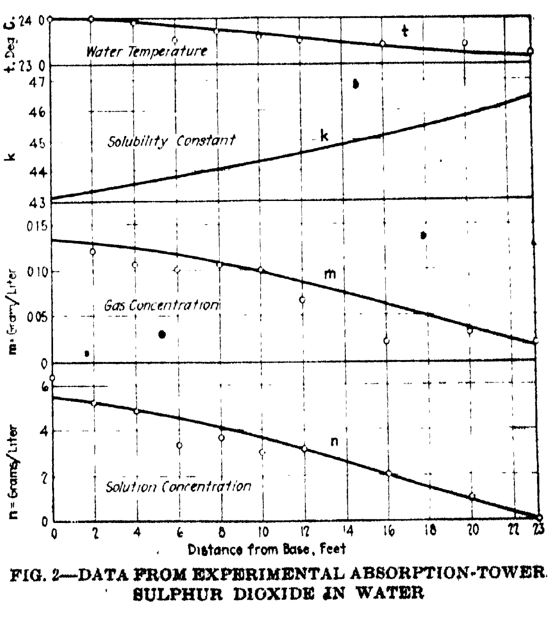

FIG. 2—DATA FROM EXPERIMENTAL ABSORPTION-TOWER SULPHUR DIOXIDE IN WATER

*This experiment, with a number of others which cover the general subject of tower performance, will be more fully described in a future communication.

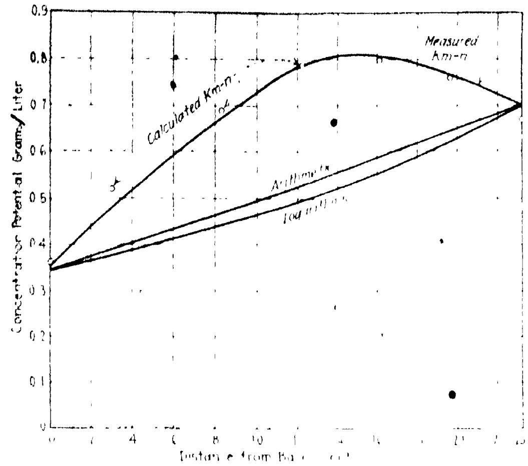

FIG. 3—POTENTIAL FUNCTION EXPERIMENTAL VS CALCULATED

3, in which the calculated potentials according to the logarithmic and arithmetic formulas are seen to have entirely different modes of variation than that of the measured potential.

The observation has sometimes been made that even very large errors in the calculation of the coefficient would have no importance practically, provided the test experiments were run under very nearly the same conditions as are to be realized in the projected installation, for then the errors would cancel This view, however, appears to reduce the coefficient to nothing more than a convenient instrument for interpolation between experimental runs which do not happen quite to fit the desired case. If it be considered what a multiplicity of conditions are possible—volumes of inflowing and outflowing gas and of inflowing liquid, concentration of inflowing gas, temperature of inflowing and outflowing liquid, etc., all variable more or less independently—the desirability of generalizing the data as far as possible will be obvious. For a given type of tower and packing the coefficient should be capable of empirical expression in terms of possibly not more than three independent variables—volumes of inflowing gas and liquid and temperature of inflowing liquid—and a comparatively small number of experiments should open up, by extrapolation, the whole field of possible conditions. But such usage requires at least the accurate calculation of the coefficient.

The experiment described above was carried out in August, 1922, under the supervision of Frank M. Jones, at that time a member of this organization, assisted by six other members of the staff.

Research on Fatigue Resistance

A research into the resistance to fatigue of copper, brass and bronze will become a part of the program of tests at the University of Illinois. It will be remembered that Dr. H. F. Moore and his associates have been engaged in an investigation on endurance of steel for several years, and have published many of their important findings. Finances for the work have been supplied by a member of interested organizations and corporations. The Copper and Brass Research Association is providing funds for the new program on its own material, and will be represented on the advisory board by Messrs. George, Webster and Price.

Light Shed on Oil Shale Distillation

The amount and quality of oil that can be produced from any shale may be made to vary to an important degree by changing the temperature relations existing in the shale charge during destructive distillation, states L. C. Karrick, associate oil shale technologist of the Department of the Interior.

The rate at which the oil is formed from the shale is affected by the rate of heat supply and therefore by the temperature of the shale during its thermal decomposition. The quality of the oil formed may be controlled by alternating the temperature of the shale and therefore the rate of formation of the oil. Variations in the yield and quality of shale oils may be caused by inherent properties of the retort used, but in any event the properties of the crude oil and yield are very largely the result of the extent to which the thermal decomposition has progressed. Recognition of these principles will aid in explaining to a large degree the reasons for the wide variations in oils produced from the same shales by different "processes." These principles also may be applied in the operation of different types of retorts in order that crude oils of a type most profitable to the operator may be produced.

The Bureau of Mines has conducted an extended series of tests in the destructive distillation of oil shales, to determine the wide variations that may be effected in the quality and yield of shale oil by changing the rate and temperature at which the oil is formed. These tests furnished interesting information on the four related points: Yield of oil, quality of oil, temperature required to distill shales, and time required for distillation Serial 2456, which just has been issued by the Department of the Interior, Bureau of Mines, Washington, D. C., gives this information in detail.

Industrial Research on Lime

The extent of the use of lime is a matter of general knowledge among technical men. There need be no elaboration of its many uses here. It is interesting, however, to consider some of the research that is under way under the auspices of the National Lime Association. In the first place, the organization has a research laboratory in Washington where the general subject of the fundamental properties of the commercial lime is being studied. Samples of lime from every part of the country are studied in an attempt to correlate such properties as density, porosity, reactivity, rate of settling, etc., with one another and with perhaps other properties not yet definitely determined.

Together with this fundamental investigation, some units of which have already appeared in *Chem & Met.*, the laboratory deals with other problems such as new uses for lime, control of quick-setting lime mortar, aqueous lime paints and such problems as the new users of lime are facing. In addition to this extensive work, a fellowship is maintained at Ohio State University under J. R. Withrow, who is studying the effect of varying conditions of burning on properties of lime. At Massachusetts Institute of Technology, R. T. Haslam is directing an investigation on the chemical systems in lime mortar and lime plaster. At Indiana University, F. C. Mathers is studying lime and mortar and various uses of lime. And finally, W. E. Emley at the Bureau of Standards is co-operating in a study of the construction uses of lime. This is a constructive program which other national associations could well afford to imitate.

Machinery for Bagging Superphosphate

By Kai Warming

Translated by George Frederick Zimmer

Editor's Note: *This article is most interesting in discussing one of the operating problems of the fertilizer manufacturers abroad. Some phases have only a remote bearing on our own practice. Nevertheless the work is illuminating and well worth careful study.*

MAKERS of superphosphate always find great difficulty in securing the rapid despatch of their large stocks during the busy spring and autumn seasons, because the superphosphate in the stock piles frequently becomes very hard, so that the work of getting it out, breaking it down and packing into bags is a slow and expensive operation which delays the execution of orders.

Drawback of Existing Appliances

The first machines employed for doing this work were set up near the stock pile and the superphosphate was shoveled by one or two men into a bucket elevator, which raised it to the crushing rollers. From these it dropped into bags suspended at the mouth of two chutes; each bag was weighed on leaving the bagger. Although by this method a certain amount of labor was saved in comparison with purely hand work, the machine still had to be fed by hand and was by no means automatic, so that there had to be taken into account the hand labor necessary for breaking down the pile and carrying the superphosphate some distance to the machine. Moreover, work had to be stopped at intervals, in order to shift the machine and weighing apparatus as the men got further into the pile.

The author was therefore led to consider the possibility of devising an apparatus capable of performing all the various operations. When in 1913 he took up the question, he found that it was possible to combine the swinging and digging elevator applied for several years in the warehouses of the German potash manufacturers, with the necessary pulverizers, screens and bagging scales, into a practical and useful labor-saving apparatus for superphosphate handling.

The construction of the machine was planned and carried out in Hamburg in collaboration with the engineer, Paul Burgdorff.

Construction of the Machine

The apparatus consists of a large four-wheeled motor truck driven by an electric motor, current being supplied via a flexible cable. The two large front wheels are driven by separate gearing, so that the truck can turn in a circle of small radius. It can also be run in either direction. The front of the truck carries a bucket elevator, the buckets being provided with cutting edges. The elevator is nearly vertical and is adapted to swing horizontally through an angle of approximately 90 deg. about a large vertical pivot, so that the elevator can cut a trench in the stock pile slightly broader than the overall width of the truck. The swinging and scraping movements of the elevator are imparted by two electric motors, and the change of the swinging direction at the end of each swing is effected automatically on reaching its maximum.

When the machine is set to work the elevator buckets scoop the superphosphate out of the stock pile to a depth of about an inch over an arc corresponding to the radius of the swinging movement, the material being taken out right up to the top of the pile. On the completion of the swing the machine is moved forward a suitable distance without stopping the scooping and swinging movements.

The superphosphate collected by the buckets is discharged onto a screen, and the large lumps are broken in a roll crusher and afterward screened. The sifted product is carried by a shaker and delivered into hoppers at the back of the machine on which the bags are hung; two or three bag scales are arranged underneath the hoppers. As each bag is filled the delivery slide of the hopper is closed and the bag is placed on a conveyor, to be removed, tied and sent off.

Machines of this type are made in several sizes for storehouses, ranging from 10 to 22 ft. in height. The smaller sizes have a capacity of 125 to 150 bags (of 100 kg. each) per hour, while the largest will fill 150 to 180 bags. In the larger machines the hoppers for the fine powdered superphosphate with the bag scales are paced on a separate three-wheeled truck drawn by the motor truck. Furthermore, they have a platform for the operator placed over the shaker conveyor, from where he has a complete view of its workings. Three workmen are needed to operate the machine under the supervision of a foreman, and the latter can learn how to run the apparatus in a few hours.*

It should be noted that in digging the superphosphate out with these devices it is taken uniformly from all strata of the pile. This is an advantage from the manu-

*See also article in *Industrial Management* for March 23, 1922, "The Mechanical Handling of Superphosphate," by G. F. Zimmer.

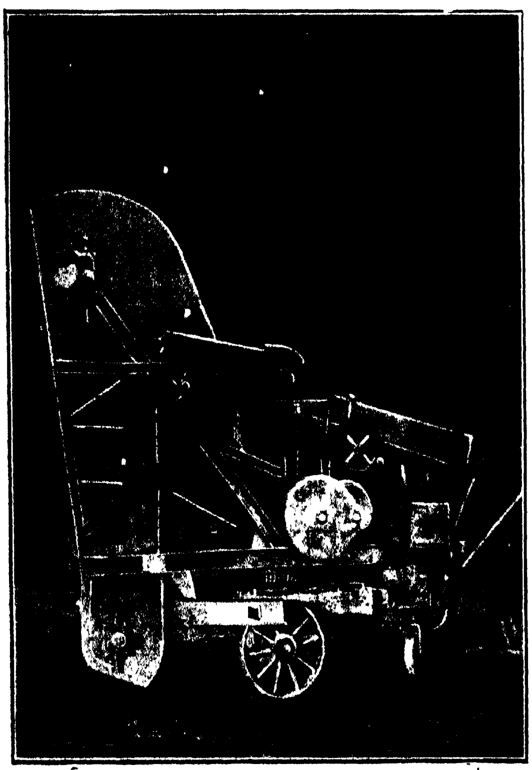
facturers' point of view, since it often happens that some batches of the product do not contain the exact percentage of soluble phosphoric acid desired and consequently have to be covered, in the stock pile, by a layer made with different proportions of ingredients in order to get a true average. In breaking down the pile it is important that these layers of different composition should be thoroughly mixed and a uniform product obtained, which is difficult to do by hand, whereas the machine scoops out the product in the desired proportions, corresponding to the different thicknesses of the superimposed layers. If necessary, this property of the machine can be utilized in the production of blended or compound fertilizers, the various components being superimposed in horizontal layers, so as to get the ingredients in the required proportions, and the pile is taken down in vertical cuts with the machine, thus producing a homogeneous blend.

Comparison of Working Costs

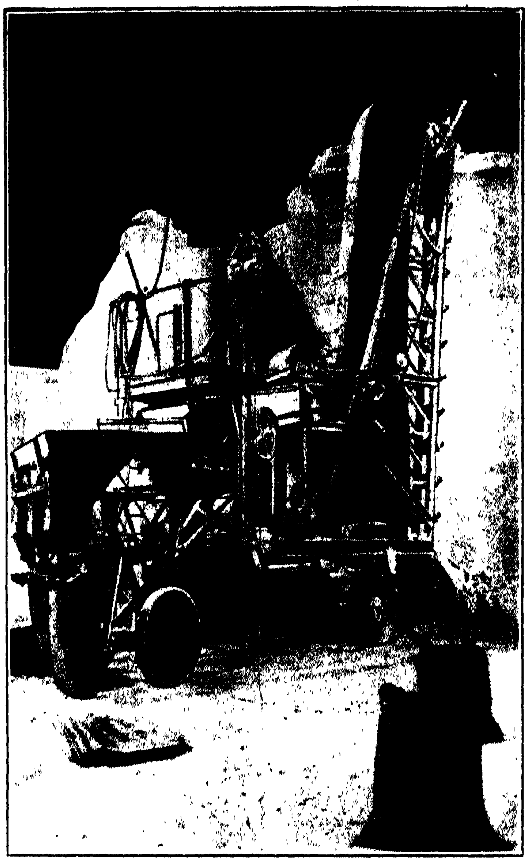
With regard to the relative costs of bagging superphosphate by hand labor and by the machine, the latter works 5 months in the year (the busy season)—that is, for 125 days of 8 hours each, or 1,000 hours in all. The work of bagging, including all the operations necessary for breaking down the pile, screening, crushing, bagging and weighing the superphosphate, tying the bags and loading them on to the wagon, is performed by eight men, at a cost of:

	Francs Per Hr
Labor, 8 men at 3 francs	24
Motive power, 20 hp at 0.25 franc	5
Upkeep of machine	5
Total	34
Output: 150 bags per hour, equivalent to	0.23

With hand labor the same eight men would fill only



ONE OF THE EARLIEST MACHINES



A MODERN BAGGING MACHINE IN ACTION

60 bags per hour, equivalent to a cost of 0.40 franc per bag. The difference is therefore 0.17 franc per bag, or 25.25 francs per hour. In 1,000 hours the profit would be 25,000 francs, which would enable the prime cost of the machine to be written off in a short time.

Increasing Output Per Man-Hour

One of the greatest advantages of the machine is that it enables the output per man to be increased from 750 kg. per hour to 1,800 kg., which is a highly valuable factor during the busy season.

Another advantage accruing from the use of these machines is the greater weight of the full sacks. It seems rather peculiar that the machine could give a greater accuracy of weighing than the ordinary balances, but it has been proved that the vibration of the machine and the weighing scales make those more "living" than ordinary standing scales. The accuracy of the weight has proved not to exceed ½ per cent, in either direction, which gives a considerable advantage both to the seller and to the buyer.

The machines can be used for all such materials as "stands" in piles, such as potash salts, sulphate of ammonia and sodium chloride, which are delivered to the sack in fine powder.

These machines have been experimented upon and successively improved in the Danish superphosphate works, where fifteen of them now replace all the former manual labor. It is impossible to prognosticate the future of such a machine, as the factors vary so much in different countries.

AMERICAN OIL CHEMISTS SOCIETY AT HOT SPRINGS

Fourteenth Annual Convention of American Oil Chemists

THE 1923 convention of the American Oil Chemists' Society in Hot Springs, April 30 and May 1, will go down in the annals of the society as one of the most important in its history. There were more than fifty members present, nearly one-fourth of the entire society. Many of the past presidents, and other leaders in the technology and chemistry of fats and oils, took an active part in the proceedings. All the large packers and vegetable oil producers had from one to ten chemists at the meetings. Several of the soap makers were represented, and most of the commercial chemists of the South were on hand.

The program for the 2-day meeting consisted of reports from various standing committees interspersed with papers and addresses on different phases of the manufacture of edible and technical oils.

Election of Officers

The final session of the meeting closed with the election of officers for the coming year. They are as follows: H. B. Battle, Montgomery, Ala., president; H. J. Morrison, Procter & Gamble, Ivorydale, Ohio, vice-president; P. P. Hinterlang, International Refining Co., San Antonio, Tex., second vice-president; J. R. May, Jr., Barrow-Agee Laboratories, Shreveport, La., third vice-president; Thomas B. Caldwell, Law & Co., Wilmington, N. C., secretary-treasurer; Herbert S. Bailey, Southern Cotton Oil Co., Savannah, Ga., editor, and A. W. Putland, Portsmouth Cotton Oil Refining Corporation, Portsmouth, Va., assistant editor.

These officers constitute the governing committee, the personnel of which is somewhat changed this year owing to the addition of two vice-presidents, the editor and assistant editor as elective officers. Heretofore the committee has consisted of the president, vice-president, secretary-treasurer and the four most recent presidents of the society.

Banquet

Tuesday night, after all the business of the convention was well out of the way, the members with their wives and guests enjoyed a most delightful banquet in the private dining room of the Eastman Hotel. David Wesson as toastmater staged several unique stunts, such as having the waiters fill all the glasses, after the guests were assembled, with perfectly clear water, which immediately turned into delicious *looking* wine. He was suspected of having used a phenolax tablet to perform this classic miracle.

This year for the first time the society had as banquet guests and speakers both the president and the vice-president of the Interstate Cottonseed Crushers' Association.

With the consignment of the loving cup once more to the custody of Mr. Battle, the forteenth annual convention of the American Oil Chemists' Society was brought to a fitting climax.

L. M. Tolman's Presidential Address

The society, in the opinion of L. M. Tolman, retiring president, has during the past 2 years become much more representative of the entire field of fats and oils than under its old name of Cotton Products Analysts. While among its members are to be found nearly all the chemists of the great American edible oil industry, it must continue its efforts to attract those interested in the paint, varnish, soap and other technical oils. He advised against joint meetings with the American Chemical Society, pointing out that at these meetings it would be difficult for those interested in a single field of chemistry to concentrate on their own specific problems.

The greatest contribution the society can make toward the advancement of this country's position in the world's oil industries is, in Dr. Tolman's opinion, along the lines of improvement in methods of analysis. Much has been accomplished by the Smalley Foundation work to perfect the procedures and technique in the determinations of oil and ammonia. The collaborative work of the society should now be extended to cover more thoroughly other analytical methods and increase the proficiency of its members in all lines of laboratory control.

Bleaching Processes Discussed

The problem of how best to bleach an edible oil is today receiving perhaps more attention than any other single phase of the general refining process.

William Kelly of the Filtrol Co. of California read a paper on the bleaching earth Filtrol. Its source is a deposit of impure silica on the edge of Death Valley, hence it is sometimes known as Death Valley clay. The raw material is refined in Los Angeles to a finished product which is pure silica with about 7 per cent of aluminum silicate. It is claimed that besides its ability to absorb coloring matters from vegetable and mineral oils, Filtrol will remove sulphuric acid, free sulphur compounds and moisture. This makes it especially suited to the bleaching of lubricating oils. Since with vegetable oils this earth can be used at a much lower temperature than is commonly employed with fullers earth, there is no tendency for the oils to oxidize or become rancid. To the soap makers this new bleach would be of especial interest if the laboratory results can be duplicated in the factor. Crude coconut and

soya bean oils bleached with it yield soap which will not darken.

In addition to fullers earths most refiners are now using chars or activated carbons in their bleaches. A. A. Jackson, who is with the Darco Sales Corporation, after discussing briefly the development of carbons for the removal of coloring matter from sugars, sirups, glycerines, oils and similar products, described the process by which Darco is made and told of its various uses. He said that while wood chars are good absorbents for gases, as a rule they did not possess any great decolorizing properties.

The decolorizing powers of a carbon may be increased by simply heating it out of contact with air; by impregnating the raw material or char with certain chemicals, heating and then removing the impregnating agent, or by simply heating the raw material in a current of steam or gas to prevent too rapid oxidation during furnacing.

Many materials have been used for the production of so-called activated chars: grasses, hulls, leathers, blood, hoofs, horns, paper mill waste and lignite. It is this latter substance which is the basis of Darco carbon. The plant is located in the Texas lignite field at Marshall. There the raw material as mined is crushed, and furnaced by a special process which is claimed to yield a very active carbon. The color absorptive power is then further increased to "an established point of standardization" by the extraction of impurities with solvents.

In the use of chars for bleaching vegetable oils, it is customary to mix them with fullers earth. Darco, said Mr. Jackson, works admirably in such combinations, but can also be used to advantage by itself. He believed that shortly such chars would largely replace all fullers earth bleaches in the edible oil business.

Vacuum Refining and Super-Deodorization

Two papers covering refining under vacuum instead of at atmospheric pressure were presented on Tuesday. This is a comparatively new idea to the American refiner and these communications aroused considerable interest. Louis C. Whiton, representing the Bataille process, described methods and apparatus not only for neutralizing the free fatty acids but for bleaching and deodorizing under vacuum. He claimed for his refining process that the soap (foots) being dehydrated would settle more readily and with less occlusion of oil than in the present open kettle procedure. Also that one could get a much more intimate contact between the lye and oil without the danger of emulsion formation. This meant the refined oil was of exceptionally low acid content and that the usual saponification loss was somewhat reduced. Bataille recommends a horizontal instead of vertical refining kettle. After neutralization with a fairly strong lye and the evaporation of the water, which takes only about 2 hours, the batch is discharged into a large settling tank. Thus the vacuum apparatus need not be very large (10,000 lb. capacity), as the batches are put through it about ten times as fast as in present practice.

Mr. Whiton believes that there is an advantage to be gained in bleaching with fullers earth in vacuum. Operating data obtained over a period of years in Europe indicate that the loss due to absorption of oil in the bleaching earths or chars is less under vacuum, as only 40 to 60 per cent of the usual amounts of these bleaches is needed. A possible explanation is that at reduced pressure all the moisture which is known to interfere with color absorption is removed from both oil and earth.

Super-deodorization is the term applied by Mr. Whiton to the process of deodorizing at extremely high vacuum and comparatively low temperature. Since the amount of objectionable odors and flavors removed by a given weight of steam is proportional to its volume, the higher the vacuum the more work it will do. The actual daily operating vacuum of the Bataille super-deodorizer is 29.7 in., with a 30-in. barometer. Under this small pressure it is estimated that steam has a volume six times as large as at the usual 28.5-in. vacuum. This high vacuum is obtained in practice by stepping up a high, primary vacuum with a special type of steam ejector. With cottonseed oil the deodorization is carried on at 295 deg. F. and requires from 1 to 2½ hours. Such plants have been in operation abroad for nearly 9 years and more than 100 are in regular use. It is claimed that in these the quality of the finished oil is superior to those obtained where lower vacuum is used, as the Bataille system removes some substances that are not volatile at a higher pressure than is maintained in the "super-deodorizer."

Francis M. Turner, chemical engineer with T. Shriver & Co., in his paper, which was illustrated with many interesting samples, spoke of the dealbuminizing process he is developing for the treatment of crude vegetable oils, and his procedure for vacuum refining. In the dealbuminizing treatment he removes the so-called "gums" or "albumins" by a simple process, the details of which were not disclosed, and then bleaches without refining. A sample of coconut oil exhibited was free from rancidity, although it was 2 years old and had never been refined, merely dealbuminized. Dr. Turner's results with vacuum refining were similar to those obtained by the Bataille process. The soapstocks he showed were hard and dry and nearly free from the disagreeable odor common to most soapstock.

Chemical Constituents of Cottonseed Oil

Two of the most instructive papers, "chemically speaking," were those by George S. Jamieson of the U. S. Bureau of Chemistry. One of the problems his laboratory has been investigating is the composition of the free fatty acids of cottonseed oil. He concludes that the acids are set free by hydrolysis in practically the same proportion as they occur as glycerides in the oils.

Even more valuable were the results reported by Dr. Jamieson on "Some of the Non-Glyceride Constituents of Crude Cottonseed Oil." Practically all of the complex chemical bodies forming the "gums" which gradually settle out of filtered crude cottonseed oil on long standing have now been identified. This gum, which is physically similar to the "foots" of linseed oil, will separate more rapidly if moisture is present in the oil, and changes in temperature also hasten its sedimentation.

At the request of the editor, a special committee was appointed to consider the feasibility of publishing a quarterly to be known as the *Journal of the American Oil Chemists' Society*. This committee made a tentative report stating that it believed it would be possible to finance such a quarterly and hoped to begin issuing with 1924.

The Rarer Metals

A Symposium Held at the Recent Meeting of the American Electrochemical Society

THE outstanding technical feature of the recent New York meeting of the American Electrochemical Society was the session on the "Rarer Metals" conducted by F. M. Becket. The opening address was made by Prof. Charles James of New Hampshire College, who has gained a world-wide reputation through his remarkable researches on the rarer metals. Notwithstanding the fact that much time has been spent searching for methods for detecting the rare elements, in many cases good methods of separation are completely lacking. Present means of separating columbium from tantalum are very unsatisfactory. So far as quantitative analysis is concerned, the greatest problem is found in the case of the cerium and yttrium groups of metals. The separation of the two groups is an extremely tedious matter which is rarely carried out.

When Is an Element Useless?

When an element is condemned as being useless, it is evident that its characteristic properties are deeply hidden. Germanium, which once seemed useless, is attracting much attention in the medical world, because of its action on the blood. The element occurs in argyrodite and canfieldite and to a minute extent in some zinc ores. A very important discovery is a copper sulphide ore of Africa containing as much as 7 per cent germanium. Work at New Hampshire College indicates that the metal can be easily extracted in an exceedingly pure condition. There is therefore a possibility that it will become sufficiently plentiful that its effect upon metals and alloys may be determined. Copper with 5 per cent Ge is a pale gold-colored alloy.

Thulium oxide on careful heating gives a beautiful carmine-colored light, which changes as the temperature is raised, becoming yellow and then almost white. The reduction of beryllium compounds presents very great difficulties. An elaborate investigation is now under way. It is important to develop a simple method for the quantitative determination of Be; such knowledge would allow us to study solubility curves and alloys with rapidity. Indium occurs more commonly than gallium in certain zinc products. Some flue dusts have shown as much as 0.5 per cent of gallium. Many other elements such as lanthanum, dysprosium, holmium and yttrium are being carefully investigated and no doubt the day is not far off when elements at present of little commercial importance will occupy a field of usefulness such as has been achieved by thorium, tungsten and vanadium.

"The Metallurgy of Lead Vanadates" was the title of the paper presented by Dr. Will Baughman of Los Angeles, Calif. He reviewed the various methods of treatment of lead vanadates and then outlined in detail his own method, which has been tried out on the Black Butte ores. In the electrolytic separation, which is an important step in the process, a mercury cathode is used. Tungsten, molybdenum and chromium pass into the amalgam and vanadium separates out as oxide. Separation can also be affected by the volatilization method: Hydrogen is passed over the mixed oxides of vanadium, tungsten and chromium heated to 1,400 deg. C. The vanadium pentoxide is reduced to the trioxide and this is readily distilled off, leaving W, Cr and Ti behind. In the preparation of metallic vanadium Dr. Baughman found lithium to be the best reducing agent. A metal containing 95 to 97 per cent V is easily obtained. Dr. Baughman's paper was discussed by Messrs. Saklatwalla, Fink and Arsem. Mr. Arsem said that the melting point of vanadium was 1,650 deg. C.

C. W. Drury, professor of metallurgical research, Queen's University, referred to the important deposit of cobalt at Cobalt, Canada, which supplies about 90 per cent of the world's demand. The Canadian ore contains about 5 per cent Co, 4 per cent Ni, 10 per cent Fe, 14 per cent As, 1 per cent Cu, 7 per cent S and 20 per cent SiO_2. The process of producing pure cobalt oxide and metal is a long and tedious one. In the production of 1 lb. of cobalt 3,000 lb. of solution is handled. Cobalt is used chiefly in the manufacture of stellite and as one of the main constituents of permanent magnets. The addition of cobalt permits magnets to be made of less than half the weight of those made of ordinary tungsten magnet steel. The demand for cobalt is greater than the supply. E. O. Benjamin referred to the cobalt plating of the iron anode in the electrolytic oxygen cell. He found that Ni-plated anodes were better than those that were cobalt-plated. Messrs. Fink and Ralston pointed out that a very good separation of cobalt and nickel is possible by electrolysis. Kenneth S. Guiterman of New York referred to the production of appreciable quantities of cobalt and nickel as byproducts in the smelting and refining of copper. The A. S. & R. had accumulated large tonnages of cobalt-nickel speiss which locked up appreciable amounts of gold and silver. The Guiterman process consists in sulphating the speiss followed by a solution thereof in water. After the preliminary removal of Fe, As, Cu, etc., NaCl is added and the solution electrolyzed between graphite anode and copper cathodes. Cobalt is precipitated out of solution as a hydrated oxide and the nickel collects on the cathode. The efficiency of the separation is about 98 per cent.

The G. E. Chromizing Process

A simple and efficient method of applying a protective coating of chromium to iron and steel was described by F. C. Kelley of the General Electric Co. The process consists of packing the material to be treated into a powdered mixture of alumina and chromium. The amount of each material used in the mixture is 45 per cent of alumina and 55 per cent of chromium by weight. The material is usually packed into a tube of iron, and then heated at 1,300 to 1,400 deg. C. in hydrogen, in vacuum or in some neutral atmosphere, for lengths of time depending upon the penetration and concentration of chromium desired. The furnaces used for this work consist of alundum tubes wound with molybdenum wire as a heating unit. These tubes are placed in a suitable furnace casing and surrounded with alumina powder, which acts as a heat-insulating material. In chromizing it is necessary to have powdered chromium of at least 95 per cent purity, for chromizing iron which is intended to withstand corrosion. Powdered Al_2O_3 is necessary as a diluting agent, and to prevent excess sintering of the powdered material at high temperatures. It is also necessary to have pure hydrogen, free from moisture and oxygen.

Discussing Mr. Kelley's paper Prof. John Johnston of Yale pointed out that the citation from Spring made by Mr. Kelley—namely, that "alloys might be produced by compression of their constituent metals in a fine state of division"—is without foundation. Johnston had

carefully investigated this matter and found that compression alone does not result in the production of true alloys. Colin G. Fink questioned whether satisfactory results were commercially possible if the chromizing process were carried out in the absence of hydrogen, he regarding hydrogen as a most essential "flux" for this process. L. O. Hart of the Driver Harris Co. suggested that it might be a good deal cheaper to use chromium-iron alloys in place of a chromized surface metal, great improvements having been made in the production of high-percentage chromium-iron alloys. H. K. Richardson of the Westinghouse company referred to his experiments on electroplating chromium on ferronickel wire for lamp seals and said that decidedly below 1,200 deg. C. penetration of the Cr into the alloy below was clearly discernible, the Cr entering the ferronickel lattice.

What Does Metallic Uranium Look Like?

"The Preparation of Metallic Uranium" was investigated by R. W. Moore of Schenectady. Starting out with the tetrachloride of uranium, this was reduced by metallic sodium and a finely powdered uranium metal obtained. The powder was compressed into pellets and these were melted with an arc in atmosphere of argon. The fused metal had the appearance of polished iron. Some buttons could be rolled cold from a thickness of about 5 mm. to small sheets about 0.375 mm. thick.

Dr. Moore's paper drew forth animated discussion. Charles A. Doremus of New York pointed out that the apparatus used by Moore resembles very closely the apparatus used by Robert Hare in 1842. J. W. Marden and H. C. Rentschler of the Westinghouse Research Laboratories have likewise for some time been studying the preparation of metallic uranium. They did not consider the chloride-sodium reduction method reliable and furthermore their metal is not brown, but looks very much like molybdenum.

James A. Holladay and Thomas R. Cunningham gave an account of the "Determination of Uranium by Means of Cupferron. The method was developed at the Union Carbide & Carbon Research Laboratories.

Hugh S. Cooper of the Kemet Laboratories, Cleveland, reported upon the very interesting results he has obtained in the "Preparation of Fused Zirconium." $ZrCl_4$ was reduced with metallic sodium and the product obtained contained 99.28 per cent Zr, the impurities being Fe, Ti and Si. The melting point of this material was determined in the Arsem furnace and found to be about 2,800 deg. C. Alloys of 60 per cent Zr with tin were found to be exceedingly pyrophoric. Zr forms alloys with Ni, Cu, Au, Al, Mg and W. Dr. Cooper showed a number of samples of new alloys.

In the discussion, J. W. Marden of Bloomfield, N. J., said that according to his experience it was impossible to avoid contamination when the zirconium was heated in the Arsem furnace. Accordingly, in recent work at the Westinghouse laboratories a high-frequency, high-vacuum induction furnace was used. The method of analysis for Zr is very difficult and very deceptive results may be obtained. The melting point given by Mr. Cooper corresponds more nearly to that of the oxide or carbide, but not to that of the metal, which is much lower. Dr. Fink felt that the Arsem furnace was one of the most convenient high-temperature laboratory furnaces made, but that time and again experimenters were using it for tests for which the furnace was not intended. There is always an appreciable residual atmosphere of CH_4, CO and probably other gases present which may affect results very markedly. He referred to his determination of the melting point of cobalt; in the Arsem furnace it was 1,490 deg. C. and in his high-temperature hydrogen furnace, 1,610 deg. C. A mere trace of carbon will depress the melting point over a hundred degrees.

A Brilliant Research on Zirconium Steel

F. M. Becket's paper on "Some Effects of Zirconium on Steel" was probably the most important contribution of the session. The Electro Metallurgical Co. has been conducting a series of scientific tests on the addition of zirconium to the steel bath and some remarkable results have so far been obtained. Zr has a greater affinity for oxygen than Si. When Zr is added to steel in excess of approximately 0.15 per cent, this element assures a new rôle by chemically combining with sulphur to form an acid-insoluble compound not detected by ordinary analysis. Zr has a greater affinity for S than Mn. The beneficial effect of small additions of Zr is strikingly demonstrated in the case of heat-treated ordinary carbon steels. The physical characteristics of the product approached those of the highest grade, heat-treated alloy steels. Zr is usually added as a silicon-zirconium alloy. Dr. Becket's paper was discussed at length by E. F. Cone, H. W. Gillett and Dr. St. John.

The report of the detailed investigation on "Treating Steels With U, B, Ti, Zr, Ce and Mo" carried out at the Bureau of Mines, Ithaca, was submitted by H. W. Gillett and E. L. Mack. It was found that Mo has a consistantly beneficial effect. In the types of steel in which the other elements were used they were either of slight effect one way or the other, or decidedly harmful. Mo is a potent alloying element. Prof. Bradley Stoughton discussed the development of super-steels and the elimination of P, S and gases. He also suggested that the elements Gillett and Mack investigated ought to be tried out as additions to pure electrolytic iron. C. P. Madsen, E. F. Cone, C. A. Doremus, Jerome Alexander and Dr. St. John also joined the discussion.

A scholarly discourse on the "Inherent Effect of Alloying Elements on Steel" was delivered by B. D. Saklatwalla of the Vanadium Corporation. He laid stress on the importance of studying the physical conditions, and their alterations by alloying elements, during the period of solidification. Too little attention has been paid to the changes in surface tension of the steel.

The three last papers of the symposium dealt with the physics and chemistry of platinum and its associated metals. Robert P. Neville of the Bureau of Standards described the "Preparation of Platinum and of Platinum-Rhodium Alloy for Thermocouples." The melting was carried out in a Northrup high-frequency furnace in crucibles of lime and thoria. H. K. Richardson referred to his thoria crucibles as being made by regular ceramic methods. Fred E. Carter of Baker & Co. did not consider the metal made in the high-frequency furnace superior to the best grades on the market.

Edward Wichers and Louis Jordan told of the "Investigations on Platinum Metals" carried out at the Bureau of Standards," a very comprehensive study.

Fred E. Carter of Newark, N. J., presented a report of his experiences with the "Metals of the Platinum Group." The tendency to absorb gases is very marked and in consequence difficulties arise during melting. The addition of iridium to platinum raises considerably the temperature required for annealing.

Hardness and Hardening

A Synopsis of Dr. Walter Rosenhain's Lecture, Given at Various Localities During His Recent American Tour—Parallel Phenomena Found in Many Alloy Systems Help Explain Why Steel Is Hard

A CHILD finds whether something is hard or soft by poking his thumb into it, or scratching it with his fingernails. If it dents or scratches it is soft; if it does not, it is hard. We grown-up children do something much like this, only we use a steel ball instead of a thumb, a sharp jewel instead of a nail and a power press for muscle.

Such methods give only a relative idea of hardness. Furthermore, it should be remembered that a pile of sand or brick is extremely hard if one is thrown against it, yet is quite soft toward piecemeal removal. It follows, therefore, that the scale of hardness varies with the tool used.

With these considerations in view, Dr. Rosenhain defined hardness of a material as the power of resisting the local displacement of portions of its substance; to the degree of strength, cohesion or resistance it offers to piecemeal removal. It follows that this property is allied to the unit stress which can be borne without permanent deformation.

How does a material resist applied forces? We here may divide substances into two general classes, viz., those capable and those incapable of plastic deformation under stress. Metals, especially most pure metals, fall into the first category, so consideration must now be given to the nature of plastic deformation. We are also enabled to push our definition of hardness one step further, by noting that it is a function of the resistance a metal offers to plastic deformation.

It is perhaps trite to repeat that plastic deformation in metal occurs by means of block movements within the individual crystals of the aggregate. As a matter of fact elongated grains in severely worked metal are still essentially crystalline—probably highly fragmented, but consisting of crystalline particles. For instance, if a piece of pure iron be squeezed in a vise while constantly under microscopic examination, its smoothed surface will acquire permanent marks, roughly parallel to one another within individual crystals, but in different directions in adjoining ones. Further stress multiplies these lines and develops second or third sets of intersecting conjugate markings. The nature of these markings is shown in Fig. 1. The crystal has been broken into blocks which move slightly past each other and then regain their rigidity. The top surfaces still reflect vertical light directly back into the microscope and appear white; the inclined slips deflect vertical light to the right and appear dark. An exact negative of the view can of course be had by side illumination from a source located in the direction of *A*. Furthermore, a surface such as this can be heavily coated with a protective copper plate, sectioned at 90 deg. and the steps and changes in level can thus be actually observed.

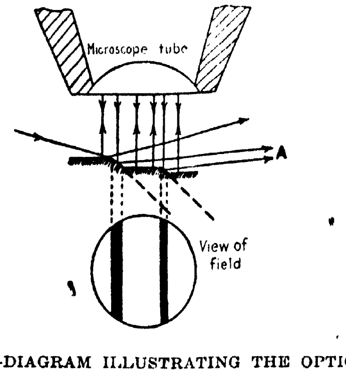


FIG. 1—DIAGRAM ILLUSTRATING THE OPTICAL BEHAVIOR OF SLIP BANDS[1]

[1]Reproduced from Fig. 108, "Introduction to Physical Metallurgy," by Walter Rosenhain.

CRYSTALLINITY CONFERS DUCTILITY

It is not so often appreciated, however, that it is the crystalline character of metals which confers the property of ductility and plasticity—that permits the phenomenon of slip. X-ray investigation has confirmed the belief that the atoms in crystals are arranged in a regular geometric order, repeating itself perfectly in the adjacent infinitesimal elements of the crystal. Very ductile metals like iron and gold crystallize in a cubic arrangement; more brittle zinc builds up a space lattice like a nest of hexagonal parallelopipeds.

Atoms are strongly held to position in these lattices by balanced forces, possibly of electrical nature, exerted by and upon all their surrounding neighbors. In fact the atoms are so strongly held that they are capable of only a relatively small displacement by outside forces. Within this range their displacement varies as the imposed force—they act in an elastic manner. Larger stresses break these interatomic bonds temporarily, and a crystal block slides along some principal cleavage plane, the atoms on each side momentarily making a change of partners.

For practical purposes the main cleavage plane of the cubic system (the 1-1-1 or octahedral plane of the crystallographer) may be regarded as quite smooth—the atoms are spaced along it in a perfectly regular manner in all directions, and they can change partners with considerable facility. In other planes, and along principal planes of more complex crystals, the atomic spacing is not so regular, and an atom once free cannot always find a new partner unless the movement stops after a well-defined interval.

Thus it is that we are naturally led to the conclusion that ease of slip, or ductility, depends upon atomic regularity in the crystal. Conversely, slight irregularities in spacing, or the occurrence of lumps or humps on the gliding planes, decrease the plasticity

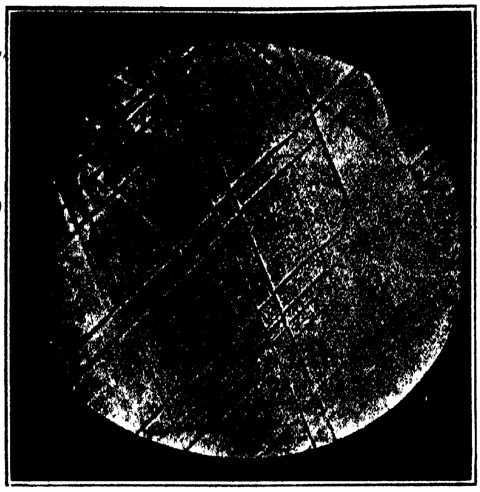

FIG. 2—SLIPS IN A CRYSTAL OF OVERSTRAINED LEAD[1] × 1,000

and increase the force required to start slip—that is to say, increase hardness. It follows directly that slip is inconceivable in amorphous (non-crystalline) material; in such substances actual fracture is necessary to bring about sudden movement.

From these considerations we arrive at the statement that hardness depends upon the smoothness and extent of the available slip planes. From this viewpoint it becomes apparent that ductile metals like iron, aluminum and copper can be hardened in various ways:

First, by producing a multitude of humps on the main crystallographic planes. Dr. Rosenhain has shown in his lecture before the Institute of Metals[3] that this always occurs when two metals enter into solid solution. "Stranger atoms" replace their hosts at the latters' position in the space lattice, but since the balance of interatomic forces is disturbed, the neighbors are slightly displaced. This roughens the slip planes, consequently solid solutions are harder than the constituent metals, often very materially so.

In the second place, a ductile metal can be hardened by fragmenting the large crystals. This is the principal effect of cold work. Although in purest metal it might theoretically be possible for a slipped crystal to remain homogeneous, in practice considerable derangement is always produced at the surfaces of slip. Some atoms always fail to find new partners, and some are more or less uneasy in their new surroundings, at least for some time. Such effects result in an upset in the space lattice, which naturally will be a zone offering considerable resistance to an incipient slip along an intersecting direction, and even greater resistance to second movement on the same plane. Successively infiltering amorphous layers therefore "fault" the crystal in many directions (Fig. 2), increase the resistance to stress; finally the metal reaches a state where ductility is exhausted and it becomes brittle, even though still consisting principally of an assemblage of crystalline fragments.

Third, hardening can be effected by increasing the amount of amorphous material at the crystalline boundaries. Where one atomic orientation meets another there must be an interface (which may be several hundred or perhaps only a few atoms thick) where the space lattice is a compromise between the two. These regions increase hardness of the metal by roughening at the ends of potential slip planes. Considerable end support is also given by adjacent grains. Furthermore, deformation transmitted across a boundary must change direction. These factors are not marked unless the grain size is very small—then they become very important indeed.

Finally, and most important, metal may be hardened by distributing finely divided hard particles throughout the crystal. This can be done by alloying a substance which is somewhat more soluble in the metal at elevated temperatures than at room temperatures. On cooling the then insoluble material precipitates as very fine and highly dispersed particles; if the cooling is at a proper rate these particles cannot coagulate to any extent, and the result is that the crystalline lattice of the mother material is not only interrupted by these particles, but itself is largely in an amorphous condition following the disruption of the lattice necessary to eject the insoluble material. In fact, the latter factor (amorphitization of the solvent material) is the principal reason for the intense hardening possible by this method, in Dr. Rosenhain's opinion.

Three alloy systems were cited by the lecturer to show the remarkable similarity of the hardening phe-

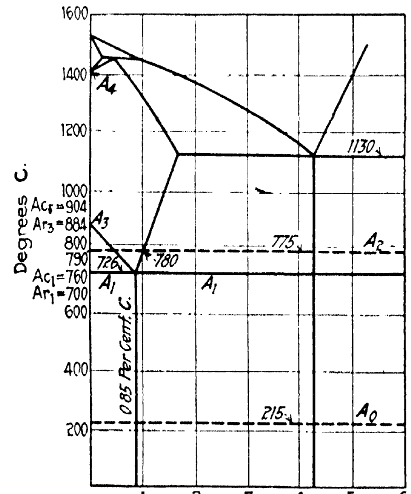

FIG. 3—IRON-CARBON EQUILIBRIUM DIAGRAM, AFTER HOWE

nomena—viz., the well-known iron-carbon series, which includes steel, the system between aluminum and the Compound Mg_2Si (duralumin), and the aluminum-zinc alloys studied by Hanson and Gaylor.[4] Figs. 3, 4 and 5 show the equilibrium diagrams. Draw a vertical line through 82 per cent Zn in Fig. 5 (point *F*) and note how the β field corresponds to the austenitic field in steel, and how a 79 per cent zinc alloy would develop a truly pearlitic structure on slow cooling. It is obvious that the inclined lines bounding the solid solution fields merely indicate how the solubility varies with the temperature.

In all these alloys a quench at a rapid rate from a correct temperature to a sufficiently low temperature will retain the solid solution practically intact, but in

[4]"A Further Study of the Alloys of Aluminum and Zinc," by D. Hanson and Marie L. V. Gayler, *J. Inst. Metals*, 1922.

an unstable condition, and the metal, while much harder than in the pure state, is much softer than it can be made. The metal may be said to be in the austenitic state. It is a mere detail that the Al:Zn alloy must be quenched and held in liquid air to retain austenite. If the speed of cooling be slightly lower, or if the drastically quenched metal be warmed somewhat, it becomes very hard. Either operation gives the necessary time and atomic mobility so that the unstable solid solution may break down into two phases—viz., minute crystals of a new phase and a disarranged lattice of the original. This condition (known in steel as martensite) will give maximum hardness because offering maximum resistance to slip; gliding planes are almost absent. Again, it is only an incidental fact that the tempering or drawing temperature of duralumin is at or lower than the atmospheric, therefore quenched duralumin "ages" or hardens spontaneously for several days.

Slower cooling or higher tempering will allow the metal to more nearly approach its new equilibrium; the crystals of the second phase (Fe_3C in steel, Mg_2Si in duralumin, and β solution in Al:Zn alloys) will grow in size, and the mass of the material (ferrite in steel, aluminum in duralumin and α solution in Al:Zn alloys) will reorganize its lattice and accumulate into larger crystals. With this the possibility of slip returns, the metal loses hardness slightly, and the microscopic appearance known as troostite may be found. It happens that Al:Zn alloys, quenched in liquid air and warmed to room temperature, temper (that is, separate into two phases) so fast that the latent heat liberated by the chemical and physical reactions will warm them so they cannot be handled with comfort within a few minutes. This phenomenon is a beautiful instance of recalescence occurring at low temperatures.

Changes in the same direction occur if greater freedom is offered. Under the microscope we may observe sorbite and finally a mixture of well-differentiated phases characteristic of pearlite will appear possessing only a moderate amount of hardness, but considerable ductility. Thus it is that the whole theory of hardening and tempering is applicable for a wide variety of

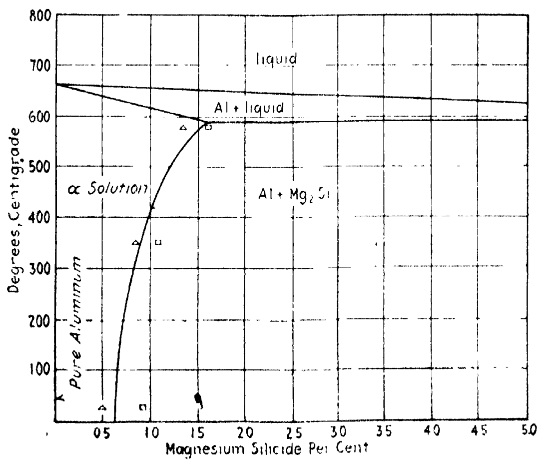

FIG. 4—EQUILIBRIUM DIAGRAM BETWEEN ALUMINUM AND MAGNESIUM SILICIDE[5]

[5]Reproduced from Fig. 36, "Constitution and Age-Hardening of the Alloys of Aluminum With Magnesium and Silicon," by D. Hanson and Marie L. V. Gayler, *Journal Institute of Metals*, No. 2, 1921, vol. 26, p. 321.

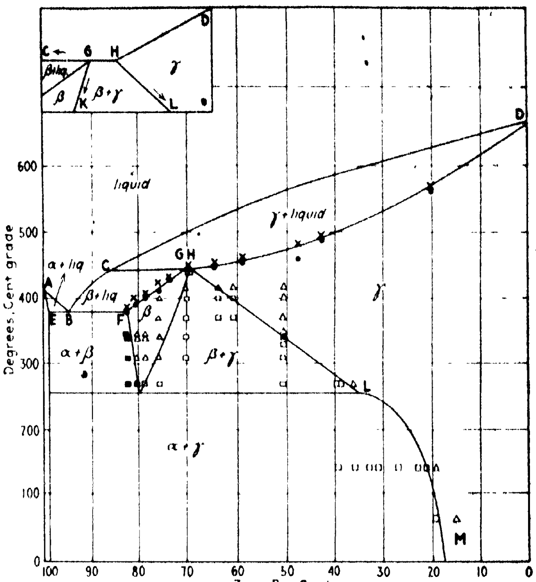

FIG. 5—ALUMINUM-ZINC EQUILIBRIUM DIAGRAM[4]

duplex alloys whose mutual solid solubility increases with temperature and whose crystalline phases are the one quite ductile and the other less so.

While detailed figures on the properties which may be induced in the aluminum alloys by heat-treatment will be covered in a later lecture, it is not amiss to emphasize again the nature of martensitic steels.

Westgren has investigated by X-ray methods the space lattice of carbon steel at 1,000 deg. C. (austenite) and finds it to be face-centered cubic arrangement.[7] If this lattice acts as a host to enough carbon, manganese or nickel atoms so that its normal activities are dampened, it can be quenched to room temperature and appear as relatively soft austenitic steel. But if this austenite decomposes slightly on cooling, it becomes intensely hard. Here again the X-rays tell us that this martensite contains particles with body-centered lattice (i.e., ferrite or alpha iron) crystals so small as to be about the size of colloidal gold—i.e., about 100 atoms in diameter. No spectral lines from the previous face-centered lattice are found. Dr. Rosenhain interprets this fact to mean not that *all* the iron was transformed from gamma to alpha, but that the bulk of the iron is quasi-amorphous—disrupted by the precipitation of carbon and the formation of colloidal grains of ferrite. Such crystals of ferrite have little or no keying action—ferrite in itself is too ductile to halt an impending slip in a surrounding crystal. The true reason for the hardness is the disorganized condition of the matrix. Whether carbide crystals are present at this stage, or whether the molecules of cementite have formed is doubtful. X-ray analysis of martensite shows no lines due to cementite crystals, but for that matter, neither would it if the same steel were annealed to the point where Fe_3C is visible under a microscope. Apparently its spectrum is such that it is masked or diffused unless it is present in great excess.

[7]In the *Journal of the Iron and Steel Institute*, May, 1922, Westgren advanced the view that carbon atoms were inserted into the center of the unit cube, but Dr. Rosenhain understands that he has recently abandoned this view for the one that a carbon atom replaces an iron atom at or near its regular position in the normal lattice. Dr. Rosenhain holds this is the make-up of all solid solutions.

Preventing Dust Fires and Explosions

Although the Explosibility of Many Industrial Dusts Is Easily Demonstrable, the Hazard Is Often Ignored and the Adoption of Effective Control Methods Delayed Until Disastrous Explosions Force Recognition of the Dangers

BY DAVID J. PRICE
Engineer in Charge, Development Work, Bureau of Chemistry

IN MANY manufacturing establishments the creation of dust is essential. The dust itself is the manufactured product, with recognized market value, and its creation is necessary in the various steps and operations followed. It is possible, however, to collect the dust and adopt effective control methods. In fact, it is an indication of efficiency in the manufacture of a product of commercial value to install effective dust-collecting systems which prevent waste of the product and dissemination of the dust throughout the plant.

We now realize that two conditions are necessary for the occurrence of a dust explosion: (1) There must be a proper mixture of dust and air in suspension, which must be of explosive proportions, and (2) this mixture must be ignited by some external source of heat or flame equal to the ignition temperature of the dust. It is now generally accepted that dust explosions cannot occur spontaneously. This must not be interpreted as meaning that there is no such phenomenon as "spontaneous combustion," which is quite a different thing from "spontaneous explosion." It is just as impossible to produce a "spontaneous dust explosion" as it would be to produce a "spontaneous gas explosion." The explosive mixture of dust or gas must be ignited.

EXPLOSIVE INDUSTRIAL DUSTS

Our knowledge of dust explosions is constantly increasing. It has not been many years since it was generally believed that all carbonaceous dusts were explosive. Experimental work has shown that at least one kind of dust which contains a very high percentage of fixed carbon—anthracite coal dust—is not normally explosive (without the presence of flammable gases), while all types of coal dust with lower fixed carbon percentages are explosive. Explosions of aluminum, magnesium and similar metallic dusts have indicated the danger of industrial dusts of this type. A few years ago the grain industry felt that unless the grain were ground and the starchy material released the dust was not explosive. It has since been proved many times, with telling effect, that dust from the handling of grains in ordinary elevating operations is highly explosive.

It must not be concluded that these disastrous explosions are confined entirely to grain handling or lines of milling, such as flour, feed, cereal and starch. All these industries have experienced disastrous explosions and suffered extensive losses. Explosions of a number of other dusts like powdered milk, fertilizer, rubber, soapine, spice, bark, sulphur, cocoa and cork have also occurred. We must expect the possibility of explosions from any type of industrial plant dusts, with the exception of inert dusts, such as shale or limestone.

*Presented before the Midyear Safety Conference held in Chicago, April 17, 1923, under the joint auspices of the Engineering Section of the National Safety Council, Chicago Safety Council and Western Society of Engineers.

It is not necessary to go into detail at this time as to the causes of dust explosions. It is probably sufficient to state that any source that will ignite the dust or cause it to burn may result in dust explosion. Attention is particularly called, however, to the possible electrical causes and other mechanical sources that have been responsible for recent disastrous dust explosions. These causes have been fully discussed in publications of the Department of Agriculture, which are available for interested safety men. It should be sufficient to state that the matter of prime importance is the control of the dust condition in the plant, together with the elimination of any possible sources of ignition.

INDUSTRIAL EXPANSION INCREASES HAZARDS

The question as to why we are having so many dust explosions in industrial plants is very frequently asked. To the investigators that have been engaged in a study of this problem for several years the opposite question seems more proper, "Why do we not have more dust explosions in industrial plants?" The industrial expansion to large-scale operation and the increase in capacity and production have increased the quantity of dust produced and added to the dust explosion hazard. Naturally, the more dust created the greater the possibility of dust ignition and explosion. The introduction of new types of milling machinery and equipment has created new ignition sources that have been responsible for disastrous dust explosions, and it must not be concluded that all the recent dust explosions have occurred from common or previously determined causes. This is not the case. On the contrary, investigators have shown many new causes that had not previously been brought to the attention of the investigating agencies.

In connection with the operation of a paper mill, an explosion recently occurred in a drier used in the manufacture of lignone from waste sulphite liquors. The liquor was sprayed into the drier and the moisture was removed by means of superheated steam. A fire started in the drier and was followed by an explosion that did considerable damage. The fire evidently started on top of the superheater. There must have been an air pocket in the drier to furnish the oxygen for combustion, although the drier was supposed to be free from air and under pressure of approximately 1 in. of water with superheated steam. The point we wish to bring out is the fact that, because of new manufacturing processes and equipment, some equipment may be installed which the manufacturer believes to be safe, yet which, through some faulty design, may increase the explosion hazard. In the case cited there should have been no air pockets in the drier and if the equipment had been operating properly no dust should have collected on the hot superheater coils.

The extent of operation of many of our industrial

establishments has greatly increased the dust explosion hazard, particularly in the grain elevator industry. At present elevators in the terminal markets of the United States and Canada are handling as much grain in a day as would be handled in several weeks on the operating scale of only a few years ago. This has naturally increased the possibility of dust settling and accumulating throughout the plant.

We can fully realize the importance of the removal of static or accumulated dust when we consider that dust explosions, as a rule, occur in two stages, (1) The primary and (2) the secondary explosion. When the explosion occurs in a plant that has recently been cleaned and where effective dust collecting methods are practiced, the nature of the explosion is localized and of a minor extent. When dust is allowed to accumulate, however, the original ignition is accompanied by sufficient concussion to shake loose the accumulated dust, which feeds the flame of the first explosion and permits it to propagate throughout the entire plant. This propagation of flame is very rapid and is accompanied by excessive pressures, which cause great damage to property and extensive life losses.

Pneumatic Sweeping Systems for Removal of Static Dust

Attention is being given to the development of effective pneumatic systems for removing static dust. A system of this nature installed in a large industrial plant collects approximately a carload of dust a day. This system has a total of approximately 2½ miles of piping, with about 650 hose inlet connections distributed throughout the building in such a manner that any part of the building or interior structure can be reached with a maximum of 50 ft. of hose.

An efficient system of this nature, installed in industrial plants where explosive dusts are handled, should be of great value in reducing the hazard of secondary explosions. Reports indicate that progress has been made in developing systems of this type for many lines of industry where recovery of the dust is desirable on account of the commercial value of the product. Engineers who undertake the development of pneumatic sweeping systems of this character should fully appreciate the problems that must be worked out before these systems can be successfully installed and operated in handling many types of explosive industrial dusts. The installation should not be undertaken until previous experimental work has shown that the system recommended is of practical value and will operate at high efficiency in the particular type of industry for which it has been designed. The progress already made by experienced pneumatic engineers is worthy of recognition and encouragement, and, in the particular installation referred to, reports indicate that the system is operating with satisfactory results.

Suggested Plan of Action

It is no longer necessary to wait until an explosion occurs with expensive results to demonstrate that the dust in any particular plant is explosive. The Bureau of Chemistry of the United States Department of Agriculture would therefore like to suggest the following plan of action for safety men in dealing with this hazard:

(1) The company should determine the degree of explosibility of dust created during the operating processes. The Bureau of Chemistry has equipment for testing any samples of dust forwarded, or the bureau can advise the company as to what methods might be followed in conducting tests at the plant. There are a number of simple methods that require very little time for determining definitely the possibility of dust ignition.

(2) The bureau is glad to suggest control methods when requested. Frequently a control method effective in one branch of industry is of value in another line. The engineers of the bureau have studied this matter thoroughly and are continually assisting industrial companies in the installation of improved equipment and control methods.

(3) If a safety committee is maintained in the industrial organization, this committee should pay particular attention to dust accumulating throughout the plant and also observe the efficiency of any dust-collecting systems in operation. We must fully realize that, after all, the proposition must be "sold" to the workman, because he is one of the most important controlling factors in dust explosion prevention. Much depends upon him and he cannot be too fully informed as to the possibility of dust explosions.

(4) All dust explosions and resulting fires should be reported promptly to the Bureau of Chemistry, in order to secure the assistance of the engineers in determining the cause and in considering methods of prevention. It is very important that explosions of limited proportions be reported and that the industrial company does not delay action until there is loss of life or property damage. The investigation of a large number of these explosions has very definitely shown that more valuable data have been secured when the explosion was of a minor nature and the destruction neither complete nor extensive. As a rule, workmen can advance information of value in establishing the circumstances under which the explosion originated, a very definite and helpful contribution to dust explosion prevention that it is possible for every safety man to render. Report the "wee, small occurrences" and thereby help to take the "bust" out of combustible dusts.

International Attention to Dust Explosions

A number of international agencies are now considering dust explosion prevention. The National Fire Protection Association, through its committee on dust explosion hazards, has devoted a great deal of time during the past year to a study of the subject as it relates to various types of industries.

The Chamber of Commerce of the United States, through the National Fire Waste Council, is co-operating with the Bureau of Chemistry in bringing the question of dust explosion control to the attention of the chambers of commerce in industrial centers. A special circular on the subject, containing valuable suggestions along the lines of possible co-operation, has been distributed to the fire-prevention committees of the chambers of commerce.

Committees on dust control in grain elevators have been organized by prominent interests in the United States and Canada, to devise ways and means for the control of dust explosions in this particular industry, in which losses have been very great during recent years.

The efforts of these agencies, combined with the co-operation of the industrial companies, should result in the reduction of losses from disastrous dust explosions and fires.

A New Flow Meter

Most flow meters are based on the principle of measuring a pressure difference caused by the insertion of some such element as an orifice, or venturi tube, in the line of flow. The meter will then consist of this element and the means for recording the flow in the pipe line.

A simple way of measuring the pressure difference caused in the line is with a U-tube or manometer filled with mercury half way up each leg and with the sides to the tube connected to the two sides of the line of flow—that is, across the orifice or venturi.

In making its new flow meter, the H.S.B.W.-Cochrane Corporation has followed this simple theory. The U-tube, if mounted on a pivoted frame and permitted to rotate on a knife edge, will take a position such that the center of gravity of the whole supported structure—U-tube, frame and contained mercury—is vertically beneath the point of support. As the pressure difference causes the height of the mercury columns to vary—as between the two legs of the tube—the tube will then rotate. Its rotation can be made to actuate a pen and in this way draw a chart showing the flow over a given period.

For practical reasons, the U-tube is designed to tilt through only a relatively small angle. In order to have a sufficiently long indicator scale for practical use, an indicating pointer is mounted with a pinion on a shaft which rotates on pivots. A gear sector attached to the U-tube meshes with this pinion. Thus a relatively small swing by the U-tube is multiplied to a large angle of rotation of the indicator pointer. A large scale, visible from some distance, can thus be used.

The pen arm is also arranged to rotate on pivots. A toothed sector attached to the pen arm meshes with a second sector attached to the U-tube beam. The radii of these two sectors are in such proportion that a small tilting of the U-tube is multiplied to a suitable pen swing. The pen draws upon a circular, clock-driven chart concentric with the indicator scale. These two records are shown in Fig. 1, which is a photograph of the dial of a Cochrane flow meter.

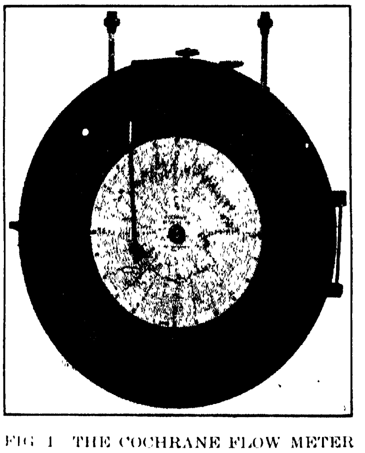

FIG. 1—THE COCHRANE FLOW METER

As the difference between the pressures on the two sides of an orifice varies as the square of the flow, both chart and indicator scale with a simple tilting U-tube would have unequally spaced divisions—that is, the lines would be closer together at low flow, becoming gradually farther apart as the flow increased to maximum.

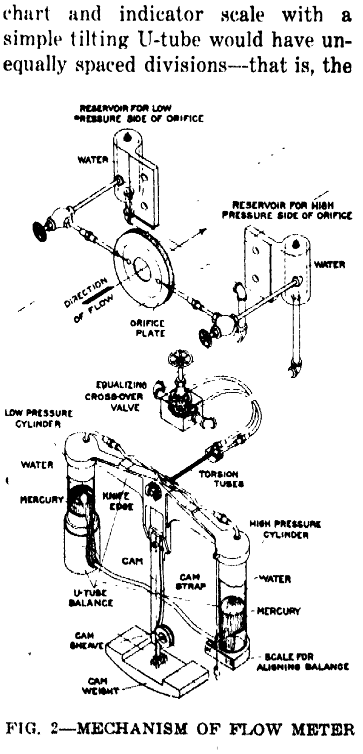

FIG. 2—MECHANISM OF FLOW METER

Uniform scale divisions and a uniformly divided chart are desirable and are obtained by the method shown in Fig. 2. A suitably shaped cam attached to the U-tube beam bears against a flat metal strap kept taut by a weight and guided by a stationary sheave. As the U-tube tilts, an increasing resistance is offered to motion. The cam is so shaped that the tilting is directly proportional to the flow that causes the difference in pressures which acts on the mercury in the U-tube.

The recording pen has a movement in a radial direction on the chart directly proportional to the flow, so that the chart can be integrated with an ordinary radial planimeter. The total pen movement is 4 in. and backlash has been eliminated. A micrometer adjustment provides for setting the pen at zero. The pen, which rests on the chart by gravity, may be lifted to permit replacement of the chart.

The standard element for creating the pressure differential supplied with this flow meter is a sharp-edged orifice in a circular plate of brass or Monel metal, ⅛ in. thick, to be installed inside the bolts, between flanges of the pipe line. Pressure connections to the two sides of the orifice are in this orifice plate itself. In this way these connections have correctly placed and sized openings, and the coefficient of discharge for the orifice is always exactly known.

NH_3 Compressors for Canada

Canadian users of ammonia compressors are to be able, in the future, to procure these machines of Canadian manufacture and standard design. The Canadian Ingersoll-Rand Co., Ltd., of 260 St. James St., Montreal, is placing on the market a line of straight-line and duplex ammonia

compressors for steam, belt, electric motor, or oil engine drive. These machines correspond to those manufactured in the United States by the Ingersoll-Rand Co. of New York. This new service will enable engineers and companies operating refrigerating equipment in Canada to procure compressors of standard design on quick delivery. The Canadian Ingersoll-Rand Co. also handles the full line of machinery, such as pumps, air and gas compressors and similar equipment manufactured by the Ingersoll-Rand Co. in the United States.

Rubber-Lined Barrel

The Cleveland Cooperage Co., Cleveland, Ohio, has recently placed on the market a rubber-lined barrel for the purpose of containing various chemicals which act on ordinary containers or are confined with difficulty and have formerly made necessary the use of glass or lead-lined receptacles.

This barrel was invented by J. H. Gravell, president of the American Chemical Paint Co. It was first used for carrying this company's products. So much interest was aroused in other shippers of similar products that the cooperage company has now undertaken the general sale of the barrel.

The barrel consists of a flexible cylinder of pure rubber suspended in a wooden barrel. The chemical to be transported comes into contact only with rubber surfaces; while the wood barrel serves to protect the rubber container and its contents.

The manufacturers of this container claim for it the following advantages: (1) A saving of 50 per cent in first cost over glass carboys. (2) A saving of 75 per cent of freight charges in long distance hauls as against the glass carboy. (3) Elimination of much breakage and a great saving in depreciation charges over other types of container. (4) A container which is easily rolled, upended, loaded and tiered and hence reduces labor costs. (5) Reduction of the number of accidents which occur when handling acid in glass.

This rubber-lined barrel is offered for the carriage of hydrochloric acid, dilute sulphuric acid, phosphoric acid, spirit varnishes, shellac, extracts, tinctures, ink, castor oil, milk, alcohol and other materials of similar nature. The manufacturers, however, caution users not to use this barrel for nitric acid, gasoline or benzol, carbon tetrachloride, soya bean oil, alcohol containing benzol derivatives or concentrated sulphuric acid.

This line is available, but the makers will sell only to a user who handles a product which test has proved the barrel will hold in a satisfactory manner.

A Unit Ash Conveyor

The medium-sized power plant not large enough to have a railway system running under the boilers for ash handling has long depended on either manual handling of ashes or on various not particularly satisfactory types of mechanical equipment. In order to obviate the difficulties encountered in this work, the Combustion Engineering Corporation, of 43 Broad St., New York City, has introduced a conveyor for this purpose called the "Combusco," which is claimed to be ideal for ash handling.

This conveyor is of the drag chain type with steel scrapers running between two strands of special drop-forged steel chain. The ashes are delivered through a spout to the lower strand of this chain, which runs in a cast-iron trough and carries the ashes out of the boiler house and—generally up a slight incline—delivers them to a storage bin from which they can be carted either by motor truck or freight car. The delivery chute has its delivery end situated inside of the cast-iron trough in which the conveyor runs and this trough is filled with water to such a height that the delivery chute is sealed by water.

It is claimed that by delivering ashes to the conveyor in this manner numerous advantages are realized. First, all dust of fumes and heat in the ash tunnel is prevented. Second, the ashes are quenched as they fall from the furnace. Third, the efficiency of the boilers is aided by the obviation of leakage at the ash discharge. Fourth, when the ashes are quenched in this manner they form a great many small pieces instead of large clinkers and are thereby much easier to handle. Fifth, it maintains a perfect air seal on the combustion chamber.

Besides these advantages claimed for this method of delivery of ash to the conveyor, other advantages are claimed for the equipment in general, such as: It dispenses with all labor except occasional attention to oiling. It permits the boilers to be built on the ground level, as it requires a trench only 4 ft. deep for installation. And because of its long life and elimination of labor it makes the cost of handling ashes per ton during its existence much less than any other method which has been so far developed.

Clean Steel

To the Editor of Chem. & Met.:

SIR—Dirty steel causes damage to watch parts in two ways. In the polishing processes used to secure a high polish on the heads of screws and on the faces of wheels, the non-metallic inclusions break out, forming a pit which injures the appearance of the part and causes its rejection. In the second place, the balance staff runs on four sapphire jewels, two of which, called endstones, bear against the ends of the staff. Non-metallic inclusions cut grooves in the endstones, causing the watch to lose its time-keeping qualities. Fig. 1 (× 50) shows such a groove in a sapphire endstone.

Several correspondents have shown photographs of dirty steel. Perhaps some would be interested to know that clean steel can be made. The accompanying photographs show the polished sections of the few samples of clean steel we have secured. These photographs are of polished, unetched, longitudinal sections, magnified 100 diameters, of samples of carbon steel drill rod.

Fig. 2 (× 100) shows the only inclusion in the section examined of a sample received in 1901. Fig. 3 (× 100) shows the only inclusion in the section examined of a sample received in 1907. Fig. 4 (× 100) shows an average section of a sample received in 1922. No other specimen has been examined here that was so free from inclusions. This specimen is polished in relief. No inclusions could be formed that, under a magnification of 100 diameters, appeared larger than a few hundredths of of a millimeter.

I believe, after examining many specimens, that the crucible steel made about 20 years ago was more free from inclusions than that manufactured today. I agree with G. F. Comstock that a specimen to be examined for nonmetallic inclusions need not be hardened before it is polished.

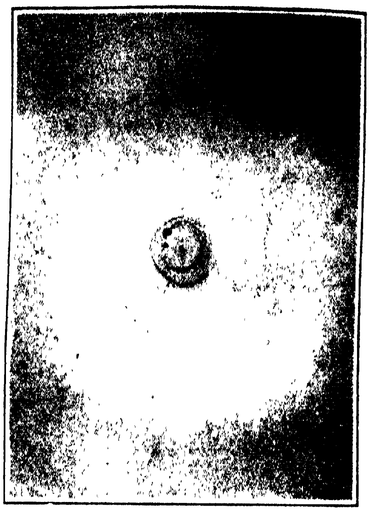

FIG. 1 JEWEL SCRATCHED BY INCLUSION IN STEEL BALANCE STAFF. × 50

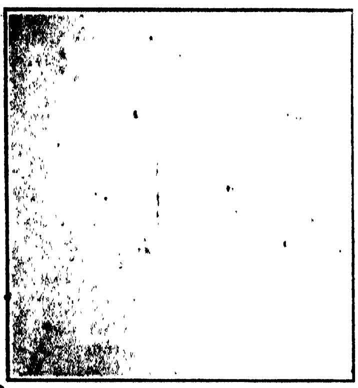
Electric Pig Iron in Brazil

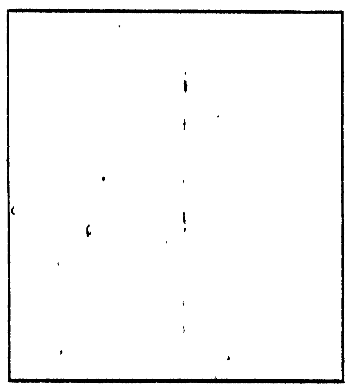
To the Editor of Chem. & Met.:

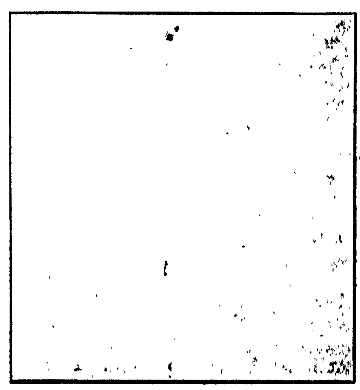
SIR—It might be of interest to your readers to learn that the first Electro Metal pig-iron furnace in America has been successfully put into operation in Ribeirao Preto, State of Sao Paulo, Brazil.

On April 1 the first tap was made and since then the furnace has been working steadily without troubles of any kind, producing 25 to 30 tons per day. From the description of our plant appearing in *Chem. & Met.* of Dec. 7, 1921, you will find that we have two furnaces, exactly alike, but only one can be operated until a new power station is completed. The furnace is of the size rated at 3,000 kw., but is provided with three G. E. transformers, each with a capacity of 1,550 kva., thus making it possible to run the furnace at a high rate, if so desired. As a matter of fact I believe that an output of 35 tons per day will be easy to attain, the limiting factor of course being the electrodes and their current-carrying capacity. Unfortunately the power supply is also at the present time a limiting factor, and we have to run the furnace very slowly. I might mention here that the smooth curve G. E. regulators, used for varying the low tension voltage from 60 to 120 volts, have proved very satisfactory, making possible a very close regulation of the power input.

When designing the furnaces we did not digress to any great extent from the standard design; only in a few details did we have to make some small changes on account of local conditions. We thought it advisable to decrease the diameter and height of the shaft on account of the higher density of the Brazilian charcoals compared with Swedish charcoals (15 lb. per cu.ft. compared with 9 lb.). The cubical contents of our shaft is only 70 per cent of the standard shaft, and the result has shown itself very satisfactory. As the gases escaping from the furnace top have a temperature seldom exceeding 100 deg. C., it is evident that the height of the shaft could be decreased even more without detrimental effects, but to do so would have meant a radical departure from the usual arrangement, as a certain distance is required between the charging floor and the floor where the electrodes are handled and joined together. For this reason the height of the shaft was hardly changed at all, but on the other hand the diameter at the bosh was quite considerably decreased. This gives the shaft a more cylindrical shape, facilitating the descent of the charge and bringing about a more effective gas circulation which







FIGS. 2, 3, 4—CLEAN STEEL. UNETCHED. × 100

Fig. 2—Only inclusion in 1901 steel

Fig. 3—Only inclusion in 1907 steel

Fig. 4—1922 steel polished in relief

at this type of furnace is of such great importance.

Another slight difference is that the electrodes enter the furnace nearer its center line than is usually the case. By this arrangement relatively cold material will always descend on the electrodes and no semi-fused mass will be formed in front of the electrodes that would prevent the descending charge from arriving in the reaction zones formed round each electrode. In spite of the small change it has proved highly beneficial, improving the regularity of the operation to a marked degree.

By this arrangement the brickwork back of the electrodes, which used to be the weakest point of the furnace, is less exposed to the heat, and the roof consequently stands up better.

The electrical connections on furnaces of the Electro Metal type have been the subject of much study and discussion. On the early furnaces diametrically opposite electrodes were always connected to the same transformer, it being taken for granted that the currents in each phase would pass diametrically across the crucible, thereby providing the greatest possible resistance to the current and making possible to operate the furnace at a higher voltage for a given power input. Investigations, however, have shown not only that such crossings of the currents are impossible, but also that the greatest voltage drop takes place just at the electrodes, the resistance of the actual charge therefore being of small importance. Hence there is no very good reason for connecting diametrically opposite electrodes to the same transformer and consequently adjacent electrodes should be connected, a method that has been followed here in Ribeirao Preto. This arrangement makes possible a very effective interlacing of the busbars, thereby cutting down the induction losses and improving the power factor.

Of course it is much too early to tell anything about the operating results. It will suffice to say that from all indications the power, electrode and charcoal consumption appears to be normal. During the last week, for instance, the furnace produced 178.2 metric tons with a power consumption of 354,000 kw.-hr., or 1,986 kw.-hr. per ton. The average load for the week was only 2,107 kw.

As to the rest of the plant, I might say that the 6-ton Ludlum furnace was put in operation last July and has been working ever since on purchased scrap, producing ingots that have been rolled into bars.

Review of Recent Patents

Treatment of Gases From Gas Producers—This invention has for its object such a treatment of the gases produced from the gasification of fuel in a gas producer that it becomes possible to obtain the most advantageous operation of the plant from a calorific standpoint and to obtain a complete and continuous conversion of the ammonia in the gas into ammonium sulphate.

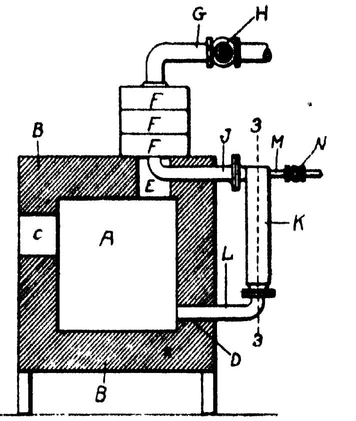
The principal point in this process consists in causing the air that is to be sent in under the grate of the gas producer to pass through the water that has served to cool the gases by spraying. The water is thus cooled and can be used again and the air is heated and at the same time charged with moisture that is useful for the production of water gas in the producer. The circulation of water and its temperature should be adjusted in such a manner that the water will condense the ammoniacal salts only—that is, such salts as do not distill in an aqueous solution—and that this water shall become richer and richer in ammoniacal salts by successive passages in the apparatus for spraying the gases. After the condensation of the fixed salts has taken place, the gases are sent into a closed saturator in which the sulphatation of the ammonia contained in the gases takes place and crystallized ammonia sulphate is produced.

In order to supply the saturator with heat necessary for dilution of the bath and for insuring crystallization of the sulphate, the saturator should be provided with a heating device fed with steam. This steam may be taken from the jacket of the gas producer or from the discharge of an engine, and afterward the steam is fed into the circuit of the air that is fed under the grate of the gas producer. The water of condensation contained in the fixed ammoniacal salts, concentrated by their successive passages through the gases, is used for diluting the sulphuric acid in a receptacle placed in line before the saturator, and in this receptacle a first formation of ammonium sulphate takes place with the elimination of harmful acids, which escape directly from the said receptacle without entering into the gas circuit at all. (1,450,562. Oliver Piette, Brussels, Belgium. April 3, 1923.)

Varnish Composition—Cheaper gums than are ordinarily used in oil varnishes may be employed in compounding if an aryl ester of an inorganic acid is added in compounding. Triphenyl phosphate is especially recommended as a suitable substance to use. Not only is it possible to use cheaper materials by employing this substance but also superior qualities are imparted to the resulting product, it is claimed by the inventors, P. Rothberg and A. P. Sachs, of Summit, N. J., and Manhattan, N. Y. (1,448,869. March 20, 1923.)

Producing Gaseous Fuel—In high-temperature furnaces such as are employed for metallurgical purposes, in order to maintain the requisite temperature, the fuel oil must be introduced into the combustion chamber in the form of a gas premixed with the proper proportion of air to effect the complete combustion. The temperature of the furnace is dependent upon the temperature of the combustion of the fuel supplied to it.

This invention is concerned with a method for preheating the air, premixing it with the fuel and introducing the fuel in the form of a vapor or gas with the correct proportion of air so that the highest possible temperature and complete combustion may be obtained in the furnace. The means for effecting this consists of a counter-flow preheater in which the air is preheated by the exhaust fumes from the furnace, a vaporizing chamber in which the oil is injected and thoroughly intermixed with the air and control valves on the air and oil supply, so that the proportion may be definitely regulated, all as shown in the accompanying cross-section of a furnace to which this type of burning equipment has been applied. In the illustration, the preheater is shown at *F*, the control valves at *H* and *N*, and the vaporizing chamber at *K*, while the gas for combustion is introduced into the combustion chamber *A* at *D*. (1,450,338. M. Sklovsky, assignor to Deere & Co., of Moline, Ill. April 3, 1923.)



Paper Pulp Process—If a small amount of hydrosulphurous acid, a powerful reducing agent, is introduced into the cooking acid used in the sulphite process, an increased and improved yield is obtained. The bisulphite liquor is made up in the usual manner and the hydrosulphurous acid, which may be made specially from such a source as sodium hydrosulphite, is added. Another recommended method of producing the hydrosulphurous acid in the liquor is that of addition of zinc

to the cook, in which case, by reaction with the sulphurous acid present, hydrosulphurous acid results. Ordinarily the addition of from 1 to 2 lb. of zinc dust to a ton of charge in the digester is sufficient to bring about the desired condition. This process has been patented by B. S. Summers, of Port Huron, Mich. (1,451,125. April 10, 1923.)

Sulphur Burner—In the manufacture of sulphuric acid by burning crude sulphur to form sulphur dioxide, there is a necessity in certain cases to use a sulphur high in ash. The purpose of the present invention is to provide a continuous burner for such a sulphur.

This burner comprises a stationary cylindrical shell forming the combustion chamber or burner proper and inclined to the horizontal at a slope of about 1 in. per foot of length. The ends of the shell are closed at each end of the cylinder, making it practically a closed combustion chamber. At the top and near the lower end is the sulphur inlet. This inlet is of the screw conveyor type and makes a positive feed. In this same end of the chamber, somewhat above the bottom, is a port which serves for admitting air for combustion and for overflow of excess sulphur. At the upper end of the drum is the ash outlet connected tangentially to the drum. This ash outlet is located somewhat above the line of sulphur in the burner, thus preventing loss of sulphur with the ashes. The outlet for sulphur dioxide is also at this upper end of the drum and is provided with a suction fan for drawing air into the burner from the other end and for removing the sulphur dioxide at this end. Within the burner is a water-cooled shaft upon which are mounted numerous paddles set at an angle, so that when the shaft rotates the ashes are conveyed to the upper end of the burner. These blades are of a comparatively narrow and ribbon-like structure, so that they will not interfere with the passage of the gases through the burner. However, in order to provide proper conveyance of the ash to the ash outlet, the blades are set in sufficient numbers on the rotating shaft so that their ends overlap. (1,450,677. Horace G. Chickering, assignor to E. I. du Pont de Nemours & Co., Wilmington, Del. April 3, 1923.)

American Patents Issued May 8, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,454,113—Oil Filter. C. A. Hamilton and B. F. Noyes, Bayonne, N. J.

1,454,112—Means for Cracking Hydrocarbons. H. A. Wier and S. A. Wier, Dallas, Tex.

1,454,153—Process of Preparing Sugar. J. Carr, Esher, and A. B. Bradley, Fulham Park, England.

1,454,211—Gas-Pressure Regulator. W. P. Capps, Shreveport, La.

1,454,214—Fused Salt Bath for Heating Steel in Hardening. R. S. Dean, Cicero, Ill., assignor to the Western Electric Co., New York City.

1,454,248—Filtering Apparatus for Air and the Like. S. J. Marx, Cleveland, Ohio, assignor to the Cleveland Air Engineering Corp., Cleveland, Ohio.

1,454,255—Apparatus for Electrical Precipitation of Suspended Particles From Gases. C. H. Weiskopf, Santa Monica, Calif., assignor to International Precipitation Co., Los Angeles, Calif.

1,454,291—Cast Metal Container. J. G. Lehman, Bethlehem, Pa., assignor to Bethlehem Foundry & Machine Co., Bethlehem, Pa.

1,454,300—Combination Agitator and Sampler. L. Sturges, Chicago, Ill., assignor to Solar-Sturges Manufacturing Co., Chicago, Ill.

1,454,301—Fluid Meter. L. E. Van Hise, Los Angeles, Calif., assignor of one-third to J. V. Baldwin, one-third to G. E. McCreery and one-third to P. F. Howell, all of Los Angeles, Calif.

1,454,341—Safety Control for Automatic Gas Appliances. G. F. Schwartz, St. Louis, Mo.

1,454,341—Solidifying Molten Sulphur. R. H. Stewart, Vancouver, Canada, assignor to Texas Gulf Sulphur Co., Bay City, Tex.

1,454,377—Process of Elevating Liquids. J. C. Grant, London, England.

1,454,411—Progressive Nitrocellulose Powder Containing Nitroguanidine. J. M. Skilling, Wilmington, Del., assignor to E. I. du Pont de Nemours & Co., Wilmington, Del.

1,454,419—Apparatus for Continuous Extraction, Particularly of Oil. M. Wilbuschewitsch, Zurich, Switzerland.

1,454,462-3—Process of Esterification and Process of Producing High-Grade Esters. A. A. Backhases, Baltimore, Md., assignor to United States Industrial Alcohol Co.

1,454,485—Process of and Apparatus for Treating Hydrocarbon Oils. J. P. Persch, Houston, Tex., assignor of one-fifth to B. Tolles, Hohokus, N. J.

1,454,491—Tube Mill. E. C. Soper, Chattanooga, Tenn.

1,454,521—Process of Making Ethyl Alcohol From Galactose. E. C. Sherrard, Madison, Wis., dedicated to the people of the United States.

1,454,564—Process of Producing Zirconium Dioxide. Otto Ruff, Breslau, Germany.

1,454,567—Method and Apparatus for Producing a Chemical Union Between Hydrocarbon Gases and Hydrocarbon Oils. H. B. Snyder, Fullerton, Calif.

1,454,581—Process of Treating Vegetable Fiber. H. C. Fueller, Jacksonville, Fla.

1,454,583—Process of Producing Magnesium Nitrate. V. M. Goldschmidt, Christiania, Norway, assignor to A/S De Norske Saltverker, Bergen, Norway.

1,454,591—Method of Treating Gases. A. Naglevoort, Providence, R. I., assignor to the Nitrogen Corporation, Providence, R. I.

1,454,593—Method of Purifying Mineral Oils. E. E. Arnold, Coventry, R. I., assignor to the Nitrogen Corporation, Providence, R. I.

1,454,599—Process of Ammonia Synthesis and Catalyst Therefor. J. C. Clancy, Providence, R. I., assignor to the Nitrogen Corporation, Providence, R. I.

1,454,604—Process of Making Glycol. W. H. Rodebush, Baltimore, Md., assignor to U. S. Industrial Alcohol Co.

1,454,606—Paper-Making Machine. J. D. Tompkins, Valatie, N. Y.

1,454,609—Apparatus for Use in the Manufacture of Aldehydes. E. J. Winter, Baltimore, Md., assignor to the United States Industrial Alcohol Co.

1,454,610—Bleaching Pulp and Apparatus Therefor. R. B. Wolf, New York City.

1,454,612—Carburizing Material and Process of Making Same. L. Aeby, East Chicago, Ind., assignor to Chicago Flexible Shaft Co., Chicago.

1,454,616-7—Process for Resolving and for Preventing the Formation of Emulsions. E. E. Ayres, Jr., Chester, Pa., assignor to the Sharples Specialty Co., Philadelphia, Pa.

1,454,687—Method of Making Acid-Proof Containers. J. E. Perrault, Watertown, Mass., assignor to Hood Rubber Co., Watertown, Mass.

1,454,694—Leather Drier. W. M. Schwartz and E. B. Ayres, Philadelphia, Pa., assignors to Proctor & Schwartz, Philadelphia, Pa.

1,454,705—Method of Extracting Oil. F. P. Croft, Philadelphia, Pa.

1,454,708—Manufacture of Carbon Bisulphide. A. E. Delph, Workingham, England, assignor to Courtaulds, Ltd., London, England.

1,454,747—Apparatus for Manufacturing Flowers of Sulphur. E. Knapp and J. K. Dickerson, Middleport, N. Y., and F. L. Begtrup, Louisville, Ky., assignor to Niagara Sprayer Co., Middleport, N. Y.

1,454,838—Concentration of Minerals. W. O. Borcherdt, Austinville, Va., assignor to the New Jersey Zinc Co., New York City.

1,454,839—Fire Extinguishing Apparatus for Oil Tanks. W. D. Witter, Roselle Park, N. J., assignor to the Foamite Firefoam Co., New York City.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Cellulose From Wood—In a process for obtaining cellulose from wood and the like by treatment with chlorine peroxide and subsequently with alkaline lye, the chlorine peroxide is used in solvents, such as dilute acetic acid, which dissolve the liquor after it has been transformed by the chlorine peroxide. (Br. Pat. 191,357; not yet accepted. E. Schmidt, Berlin, Germany. Feb. 28, 1923.)

Dioxyperylene—If dioxydinaphthyl is heated with ring-closing condensing agents, such as aluminum chloride, dioxyperylene is obtained. Basic substances, such as the oxides, hydroxides or carbonates of alkali and alkaline earth metals, are preferably added to the mixture. Specifications 165,770 and 165,771 are referred to. (Br. Pat. 191,363; not yet accepted. H. Pereira, Vienna, Austria. Feb. 28, 1923.)

Paper — A further development in utilizing rubber latex efficiently in paper making is obtained by adding a small quantity of soluble alkaline sulphide to the same before it is diluted and mixed with paper pulp in the process described in the parent specification. On addition of acid to coagulate the rubber, etc., sulphur is deposited for the subsequent vulcanization. With acid fibers, or paper sized with resin and alum, the addition of acid may be unnecessary. Sufficient sulphide to produce 1 to 2 per cent sulphur calculated on the rubber content is usually enough, but quantities to produce 10 per cent may be added. (Br. Pat. 191,446. F. Kaye, Ashton-on-Mersey. Feb. 28, 1923.)

Synopsis of Recent Literature

Utilization of Waste Lime Rock

Most of the lime manufactured in the United States is burned in various types of shaft kilns. The fuel and limestone may be added in alternating layers, as in pot kilns, or the fuel may be burned beneath the stone, the flames and hot gases passing up through the spaces between the rock fragments. The necessary draft is maintained either by a tall stack, a power fan, or in certain cases by natural currents.

The necessity of a good draft is a great detriment to the utilization of small-sized fragments of stone, for if large quantities of the finer materials are mixed with the larger masses the draft is greatly retarded and imperfect calcination results. For this reason rock below 4 in. in diameter is usually either discarded or diverted to other uses. In this way, in many cases, a large waste is entailed.

With the growing tendency toward underground operations in lime quarries the problem of utilization of small rock is becoming more urgent, since a much larger part of the rock comes out in the finely divided form.

Of the possible means of burning the smaller fragments either a rotary or a Mount kiln is most commonly used. Since either one of these types of apparatus is rather expensive, neither can be used economically unless the output of the plant is quite large. For plant operating twenty to twenty-four shaft kilns the addition of one Mount kiln for small fragments, and one rotary kiln for fine, is regarded by some as an ideal equipment which will utilize practically the entire quarry output. The Interior Department, Bureau of Mines, from whose publication this information comes, is at the present time working upon the problem of burning small-size rock in the ordinary shaft kiln.

However, as alternate means of disposing of fragments from 2 to 7 in. in diameter several possible outlets may be developed. Open-hearth steel furnaces usually demand stone not less than 4 or 5 in. in diameter, but for blast furnaces smaller stone may be used. This use, however, is limited not only by the demand, but by transportation, for it is too low priced to warrant a heavy haulage charge. Fragments unsuited for lime manufacture are used extensively for road building, and also as ballast and riprap for railway construction. However, these last two applications are of local significance only. Still further uses for small fragments are for use in terrazo floors, for facing concrete blocks, or as a substitute for sand in mortar and wall plaster.

There is also a growing tendency to use pulverized limestone as liming for land. When this means of outlet is resorted to, large storage space for the product between seasons is necessary, because the demand for agricultural limestone is seasonal. Limestone pulverized to a much finer grade than for agricultural use is finding wide application in various products. Small quantities may be added to stock food as a bone builder. A dust—approximately 80 per cent of which will pass a 200-mesh screen—is the most widely used filler in road asphalt surface mixture, although slate flour, portland cement and hydrate of lime are used to some extent. Ground limestone is used, to a limited extent, as a fertilizer filler. Very finely pulverized stone may be used successfully as a whiting substitute in certain classes of rubber, paint and other products. It is essential for such uses that it be very finely ground and uniform in size so as to exclude all comparatively large-size grains. In general the limestone flour that will successfully meet the requirements of fillers such as whiting or china clay should approximate 300-mesh size.

Seaboard Liquid Purification Process

Enough has been written of the Seaboard process of liquid purification of gas so that by this time engineers are thoroughly familiar with the theory. The process has now been in use for some time and reports of its success over a varying length of time are beginning to come to hand. In *Gas Age-Record* for April 21, 1923, H. R. Broker reports the various advantages and disadvantages of the method as they have worked out in the plant at Racine, Wis.

The apparent advantages were:

First—Low cost of installation. A wet process plant designed to obtain 90 per cent sulphur removal for 3,500,000 cu.ft. send-out costs approximately $11,000. One additional oxide box would cost approximately this amount and would not remove 30 per cent of the sulphur.

Second—Low cost of operation. As near as could be determined the cost of operation would not exceed 0.7 cent per thousand cubic feet of gas purified, including royalty, labor and materials, as against 1½ to 2 cents for the oxide method.

Third—Labor is practically eliminated. No additional men are required; the only labor connected with the process is in adding soda ash daily and in oiling pumps and fans. In any plant not sufficiently large or not adapted entirely to mechanical handling of oxide, there is a labor charge, as every operator knows, that does not show on the books. There is a tendency to carry some men on the payroll primarily to have them available when a box is to be emptied.

Fourth—By varying the strength of solution and rate of circulation, the Seaboard process is apparently capable of removing 90 per cent of the sulphur whether a 400-grain gas or 1,000-grain

Important Articles in Current Literature

More than fifty industrial technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

Solution: Rate 60 gal per M., temp 60 deg F. Actifier air 40 cu ft per gal temp 60-100 deg F.

gas is being treated. This is, of course, not true of oxide purifiers.

Fifth — Possible elimination of stopped services and ruined meters from hydrocyanic acid.

It has been known for many years that a large part of the hydrocyanic acid in the gas has been going through the oxide boxes and into the mains. During recent years a large part of the so-called rust troubles and meter troubles have been traced to this compound. The Seaboard process removes a large part of the cyanides (80 to 90 per cent), sufficient so that the oxide boxes can handle the residue.

The design and operation of the apparatus are more technical than it may first appear from the simplicity of the process, as we soon learned after putting the plant into operation. There are several factors which have a very material effect on the efficiency of operation, most noteworthy of which are the size of coke, depth of packing, rate of circulation, and type of sprays or efficiency of distribution of liquor.

The plant was started in cold weather and we immediately found that we were chilling the gas with the resultant deposit of naphthalene in the actifier. It will be noted that the actifier is quite an efficient cooler when cold air is used. We were blowing 5,000 cu.ft. of air per minute (sometimes at a temperature around zero) through the actifier and absorbing heat from the liquor; this cold liquor again coming in contact with the gas in the absorber. It was found necessary to either heat the liquor entering the absorber or to heat the actifier air.

About 2 weeks after starting the plant we got into trouble from a strong odor of hydrogen sulphide around town. This was noticeable within an area of a mile from the plant. We immediately conferred with Koppers engineers, who recommended dilution of the actifier air as it left the stack. We had two old fans at hand having a combined rated capacity of about 25,000 cu.ft. of air per minute, which were connected to the outlet of the actifier temporarily.

At the same time Prof. O. L. Kowalke was called to give us some information regarding the amount of hydrogen sulphide air would carry without detection. He advised that 1 part in 10,000 was noticeable. The actifier air contained approximately 1 part in 300, so that it would be necessary to use 35 cu.ft. of dilution air per cu-ft. of actifier air discharged, or 175,000 cu.ft. of dilution air per minute. The diluted air would need to be very thoroughly mixed and discharged above the surrounding buildings. The cost of suitable fans, stack and necessary power made this scheme prohibitive. The only remaining positive solution was to burn the actifier air.

During the time we were discharging the air into the atmosphere we had complaints of sickness that were undoubtedly in part psychological. Silverware and copper in restaurants near by turned black over night.

Up to the time of writing, the apparatus has not come up to the contemplated efficiency, but we have sufficient reason to believe that when smaller coke is put in and the sprays properly adjusted, we shall be able to get at least 90 per cent removal of hydrogen sulphide.

The accompanying table of operating data is a summary of results for 8 weeks, which time the plant was in continuous operation. From the data sheet a striking difference in soda consumed is noticeable for the last week and a half. Steam had been admitted at the bottom of the actifier to saturate the air and prevent loss of water from the soda solution, and at the same time utilize the heat in this waste steam. The difference in soda requirements when the steam was shut off shows the fallacy in its use. The results for the last week represent very good efficiency in soda requirements.

Due to the short time, and the numerous difficulties encountered, it is impossible to give a just estimate of the cost of operation.

The conclusions drawn are:

First—We have not lost faith in the process and believe it will work out satisfactorily.

Second—We feel justified in believing the process not feasible near business or dwelling houses without burning the actifier air; as our experiments with dilution, although not complete, indicate that the people controlling the process have no ground to justify their recommending dilution.

Third—The sizes of shells, fans, pumps and all engineering data will stand considerable investigation before the most efficient plant can be specified to be used under any given set of conditions.

Book Reviews

TABLES ANNUELLES DE CONSTANTES ET DONNÉES NUMÉRIQUES DE CHIMIE, DE PHYSIQUE ET DE TECHNOLOGIE. Vol. IV, 2nd Part, 1913-1916. By *Ch. Marie*, secrétaire général du Comité International. Gauthier-Villars et Cie. (Paris). University of Chicago Press (Chicago). 1922. 627-1377 pp. 22x27 cm. Price, $13.25 net.

An international committee was organized at the Eighth Congress of Applied Chemistry in London, June, 1909, for the purpose of collecting and publishing annual tables of physical constants and other numerical data. This committee published Vols. I, II and III, containing, respectively, data for the years 1910, 1911 and 1912. The preparation of the succeeding volumes was interrupted by the war. The work has now been resumed under the patronage of the International Research Council and the International Union of Pure and Applied Chemistry. The original secretary of the committee, Professor Marie, has continued in charge of the work, and Vol. IV contains data for the 3-year period 1913-1916. Work on Vol. V, containing data for the years 1917-1922, is about completed and it is hoped that Vol. VI will contain data for 1923 and 1924 and thereafter the publication again become annual.

The present volume embraces data on electricity, magnetism, atomistic properties, radioactivity, cosmic physics, atomic weights, molecular weights, transition temperatures, diffusion, osmotic pressure, solubility, calorimetry and thermochemistry, chemical equilibrium, velocity of reaction, electrolytic conductivity, electrochemical equivalents, electromotive forces, colloids, crystallography and mineralogy, organic chemistry, essential oils, fats and waxes, biology, vegetable physiology and chemistry; engineering data classified under (1) mechanical constants, (2) electrical constants, (3) physical and chemical properties of fuels; metallurgical data classified under (1) metals and alloys, (2) mechanical constants, (3) electrical constants; supplement.

The data are concisely and systematically arranged, and complete literature references are given. The manner in which the compilation is made is designed to promote completeness and accuracy. The information in all cases was collected by collaborators residing in the various countries and then forwarded to the central office in Paris. From there it was distributed to specialists who undertook the compilation of each separate section.

The total represents an expenditure of considerable effort, which is, for the most part, contributed by zealous individuals impelled by their interest in science who received either no pay or very inadequate pay. The value expressed as effort put into the compilation is certainly many times the sum

of money received for its support as grants and from the sale of the publication. A purchaser may accordingly be assured that he is not only buying a volume that is an invaluable aid to research in every laboratory, but he is supporting an undertaking designed for the general advancement of science and industry.

Furthermore, generous support is especially needed at the present time on account of the increasing difficulties of publishing the tables with the funds so far available. When one considers the very small sums that have been collected, the amount accomplished is remarkable. The undertaking is certainly one that should receive more liberal and regular support than it has in the past. ATHERTON SEIDELL.

BRIQUETTING. By *Albert L. Stillman*, E.M., M.Sc. The Chemical Publishing Co., Easton, Pa. 6¼x9 in., xl + 466 pp., with 160 illustrations. Price, $6.

The author states in the preface: "Although thousands of tons of briquets are manufactured each year, from all classes of raw materials, the only textbook to date published on the subject is the very comprehensive work 'Handbook of Briquetting,' by Prof. G. Franke, translated from the German by Prof. F. Lantsberry. It is, therefore, thought that a book on the subject, presenting it from the American standpoint, will be of interest."

The author has prepared a text on briquetting that is interesting and valuable to American engineers, in describing machinery, binders and methods for briquetting various materials with special reference to American practice. A brief introductory chapter on raw materials is followed by 71 pages describing the various types and classes of briquet presses of both American and foreign makes. Manufacturers' names are given and installations are described with comments on the commercial success or failure of the press.

Chapters III to V inclusive describe the briquetting of steel swarf and turnings, cast-iron boring and non-ferrous metals swarf and scrap. Particular attention is called to the various types of gas and electric furnaces for melting metal briquets and to the reduction of melting losses by the use of briquets rather than loose scrap.

Chapter VI, on "A Discussion of Binders," and Chapter X, on "Principles of Briquetting With Binders; The Briquetting of Coals; Combustion of Fuel Briquets," are full of valuable and practical information based on the author's extended experience in briquet engineering. He does not stop with a mere description of different types of binders, but discusses their advantages and disadvantages and the extent to which the binders and processes have proved commercially successful.

Chapter XI, on "A Chronology of Coal Briquetting in the United States and Canada," discusses the reasons for failures in fuel briquetting and points out the difficulties to be avoided in future construction. Briquetting plants are described from the first one at Port Richmond piers, Philadelphia, Pa., in 1872 to the Nukol plant at Port Stanley, Ontario, built in 1921.

Other chapters in the book cover the briquetting of sawdust, wood wastes and charcoal; the winning, drying, distillation and briquetting of peat and peat char; the carbonization and briquetting of lignite, *braun kohle* and lignite chars; the briquetting of coke braize, low-temperature cokes and petroleum carbon; briquetting of flue dust and ores; and laboratory research in briquetting. Comprehensive bibliographies and lists of patents are given at the end of each chapter.

There are a few minor errors. On page 9 it is stated that "The United States Government Bureau of Mines is at present engaged in investigating the distillation of waste straw and kindred products." It was the U. S. Department of Agriculture that made this investigation and not the Bureau of Mines.

Also on page 236 reference is made to a contract between the Bureau of Mines, John B. Adams and Fred Bremier for the erection of a commercial lignite carbonizing and briquetting plant in Dakota. This contract was not completely signed and the construction of the plant was never started. On page 237, "Grand Forge" should be "Grand Forks," North Dakota. Most of the subject matter is selected with excellent judgment that reflects the author's experience in briquetting.

A. C. FIELDNER.

THE WORKING OF STEEL. ANNEALING, HEAT-TREATING AND HARDENING OF CARBON AND ALLOY STEEL. By *Fred H. Colvin* and *K. A. Juthe*. McGraw-Hill Book Co., New York. 250 pp. Price, $3.

This is a revision of what is probably the best and most handy volume on heat-treatment so far printed. The first forty-five pages of the book, containing chapters on Steel Making, Composition and Properties of Steel, Alloys and Their Effect on Steel, cover the subject in as complete a manner as is necessary. The authors are to be commended for getting into this short space a mass of pertinent information that usually occupies far too great a volume in most text books. Much of the reading matter has been rewritten with improvement. The classification of steels appearing on page 11, and the matter on the physical testing of steels, are useful additions which did not appear in the first printing. Chapter VIII is on Heat-Treatment, and is greatly altered, especially the part that discusses the principles of the art. It is markedly improved and actually is the "heart of the book." It appears to the reviewer that this chapter should replace Chapter IV, and if it were so the authors would have condensed the subject of heat-treatment into less than 100 pages, which is truly a remarkable performance. Chapter IV at present contains some remarks on the application of Liberty engine materials to the automotive industry. In the reviewer's opinion, this is out of place. A serious crticism might be leveled that while Liberty engines might have been a war-time commodity, there is some question as to whether peace-time articles can be manufactured with the same precision.

Chapters V, VI and VII, on Forging, Annealing and Case-Hardening, contain many corrections. Annealing deserves more space than the four pages the authors have given it; the subject of normalizing—an annealing operation—is conspicuously absent. While the general treatment of case-hardening is excellent, it is probably dangerous to advocate mixing carburizers in the shop when much more uniform materials for this purpose are purchasable from a number of sources which have command of the raw materials required. Cyanide hardening is not discussed, which is a strange omission. The balance of the book, on Hardening Carbon Steels, High-Speed Steels, Construction of Furnaces, and Pyrometry, are the same as in the first edition. It is to be regretted that the authors have not inserted some more advanced tables at the end of the book, in addition to the simple ones which are now found.

Those practicing the art of heat-treatment will find that "Working of Steel" is a book containing practically everything required in a technical way for the execution of their art, which naturally employs the method of trial and error quite extensively. It is a book that should be owned by all heat-treaters, and it is believed by the reviewer that it is written in such a way as to be understandable to any intelligent person. SIDNEY CORNELL.

ilar capacity with the recently organized Cajon Lime Products Co., San Bernardino, Calif. He will also act as superintendent at the proposed plant of the new company.

R. C. TOLMAN, professor of physical chemistry and mathematical physics at the California Institute of Technology, has been elected a member of the National Academy of Sciences.

A. S. WALTER, professor of chemistry at the New Mexico School of Mines at Socorro, N. M., has been recently appointed professor of mining and metallurgy. Professor Walter has been identified with mining, milling and smelting in the West since 1907. He is the junior member of the firm R. J. Walter & A. S. Walter, consulting mining and metallurgical engineers, of Denver.

Men in the Profession

Prof. HORACE G. BYERS, head of the department of chemistry, Cooper Union, N. Y., and president of the American Institute of Chemistry, sailed May 8 on the Mauretania for a 3 to 4 months trip to Belgium, France and Germany. The greater part of Dr. Byers' time will be spent on investigating the status of the chemical industry in Belgium and France.

G. W. CLAMER of the Ajax Metal Co., Philadelphia, has been elected president of the American Foundrymen's Association. H. B. SWAN of the Cadillac Motor Co. is the new vice-president.

H. C. DICKINSON, who has been for some time on leave of absence from the Bureau of Standards to serve as director of research of the Society of Automotive Engineers, has returned to the bureau. He resumes his work as physicist and has been designated chief of the heat division. Work of this division includes thermometry, pyrometry, automotive engine investigations and the various branches of research on thermal physics.

E. H. DIX, JR., who for the past few years has had charge of the metals branch of the engineering division, U. S. Army Air Service, at McCook Field, has resigned to take charge of the new metallurgical laboratory of the Research Bureau of the Aluminum Company of America, New Kensington, Pa. Mr. Dix has been working on the production of light alloys since his graduation. During the war he was in charge of the testing department of the general laboratories of the Bureau of Aircraft Production. At McCook Field he organized a most interesting foundry which operates under strict technical control, where is worked out the correct manufacturing practice for new and old alloys.

ECKARDT V. ESKESEN, head of the New Jersey Terra Cotta Co., New York, has been elected president of the National Terra Cotta Society, rather than vice-president as previously noted in these columns. O. W. KETCHEM of Philadelphia has been elected first vice-president and ADOLPH HOTTINGER second vice-president. WALTER GEER, JR., is treasurer and F. S. LAURENCE has been elected executive secretary.

Dr. E. C. FRANKLIN was guest of honor at a luncheon given by the Chicago Chemists Club, May 7.

CHARLES HINCHMAN has been elected vice-president of the Keystone Tire & Rubber Co., New York.

A. E. MARSHALL, chemical engineer, of Baltimore, Md., delivered a series of three lectures on chemical engineering to the department of chemical engineering, Columbia University, May 8, 9 and 10.

Prof. HARRY MCCORMACK of Armour Institute of Technology and Dr. GUSTAV EGLOFF of the Universal Oil Products Co. are in Washington, testifying in the patent interference case of Dubbs vs. Isom (Sinclair Refining Co.) in connection with oil cracking. Dr. Walter F. Rittman of the Carnegie Institute of Technology and Prof. Frank Wagner of Rose Polytechnic Institute have testified for the Sinclair Refining Co.

ROBERT A. MILLIKAN, foreign secretary of the National Academy of Sciences, returned to Pasadena, Calif., recently after having delivered several addresses before scientific organizations in the Eastern states.

HERBERT FISHER MOORE, first professor of engineering materials at the University of Illinois, gave an interesting illustrated address before the members of the Engineers' Club of the Lehigh Valley, Allentown, Pa., May 7, on the subject of the failure of materials caused by fatigue stresses.

Prof. A. A. NOYES recently underwent an operation at Johns Hopkins Hospital, Baltimore, to combat an infection in his larynx. He is reported to be convalescing satisfactorily.

FRANK REITH, formerly chief chemist at the plant of the Golden State Portland Cement Co., Oro Grande, Calif., has become connected in a sim-

Society Calendar

AMERICAN ASSOCIATION OF CEREAL CHEMISTS will hold its ninth annual convention at Hotel Sherman, Chicago, June 4 to 9.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Milwaukee, Wis., Sept. 10 to 14.

AMERICAN ELECTROPLATERS SOCIETY will hold its eleventh annual meeting at Providence, R. I., July 2 to 5.

AMERICAN GAS ASSOCIATION will hold its annual convention the week of Oct. 15 at Atlantic City. An elaborate exhibition of gas-making and gas-utilization equipment is planned.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting June 20-23 at Wilmington, Del.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting May 28 to 31 in Montreal, Canada.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

CANADIAN INSTITUTE OF CHEMISTRY will hold its annual meeting in Toronto, May 29 to 31.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH) will be held in New York Sept. 17-22.

NATIONAL FERTILIZER ASSOCIATION will hold its thirtieth annual convention at White Sulphur Springs, W. Va., the week of June 11.

NATIONAL LIME ASSOCIATION will hold its fifth annual convention at the Hotel Commodore, New York City, June 13 to 15.

NATIONAL SYMPOSIUM ON COLLOID CHEMISTRY will be held at the University of Wisconsin, June 12 to 15.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

PACIFIC DIVISION, American Association for the advancement of Science, will hold its seventh annual meeting at the University of Southern California, Los Angeles, Sept. 17 to 20, in conjunction with the summer session of the national association and a meeting of the Southwestern Division of the National Association.

SOCIETY OF CHEMICAL INDUSTRY, Canadian Section, will meet in Toronto, May 29 to 31.

SOCIETY FOR STEEL TREATING — Eastern sectional meeting will be held June 14 and 15, in Bethlehem, Pa.

TAYLOR SOCIETY will hold a meeting June 7, 8 and 9 at the Hotel Onondaga, Syracuse, N. Y.

The following meeting is scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: June 8—American Chemical Society, regular meeting.

The Summary of the Week

Four dye plants, backbone of German chemical trust, seized by French.

Harry A. Curtis to head Yale's chemical engineering department.

Richard B. Moore succeeded by Samuel C. Lind as chief chemist of Bureau of Mines.

Reports to Department of Commerce, from different foreign countries, say American exporters are neglecting the trade of markets abroad, because domestic markets are more attractive.

State Department announces method of procedure to be followed by importers who desire export licenses for shipping goods from the Ruhr.

Spanish decree of April 30 extends preferential import rates to commodities entering Spain from different American republics, but the decree does not extend to United States goods.

Collectors of customs have received instructions to exact penalties on importers who release goods from custody on bond in lieu of required shipping documents, whenever the missing papers are not presented within prescribed time limits.

Demand for calcium arsenate has quieted down following uncertainty in arsenic market, and prices are easier.

Recent advances in acetic acid have been followed by an advance of one-half cent per lb. in quotations for acetate of lead.

A sale of 700 tons of coconut oil in bulk at 8c. per lb. c.i.f. Pacific Coast, was reported. This is a new low price for the movement.

Lower prices have been announced for salicylates, but all producers have not met the decline and offerings do not appear free at the lower price levels.

Manufacturers Report on Business Conditions

AT the convention of the National Association of Manufacturers, held last week in New York, a very interesting report on general industrial conditions was submitted. This report deserves more than passing mention, including, as it does, production and consumption of basic materials in the representative industries of the country. The conclusions reached are in harmony with those which have been current in trade circles. The manner in which information has been sought and obtained is strikingly different from the ordinary and gives to the report of the association an authority that is beyond dispute. The report is based on a survey of the manufacturing trades in the leading industrial centers. This survey took the form of a questionnaire to which more than 42,000 answers were received, and from this abundance of first-hand information the conclusions of the report were drawn. While the questionnaire covered a wide range of industries, the information was grouped under key industries.

According to the survey, conditions in general throughout the country are very healthy and wholesome. A large number of replies from manufacturers characterized business as excellent and further stated that prospects for the fall trade were equally bright. Those who reported business as poor formed only a small fraction of 1 per cent of the number who answered in that way in the year preceding.

Production, as compared with last year, is showing an increase of something like 40 per cent in all lines of manufacture, with excellent prospects for fall. Stocks on hand are reported generally as low or normal, indicating that sales are keeping ahead of or abreast with production, another most healthy symptom. In New York, Massachusetts, Pennsylvania, Ohio, Illinois and Indiana, the reports of "excellent to fair" for present business and fall prospects in all lines rarely fall below an average of 99 per cent, while stocks are reported low to normal by about the same percentage f. manufacturers.

Under the plan of grouping key industries, reports on activities in chemicals are joined with those for drugs, oils and paints. It is possible that unusual activity in some of these trades may bring up the average for the group, but at least an approximate idea of conditions existing in those industries may be gathered from the survey, which states that 95 per cent report present trade excellent to fair and fall prospects excellent to fair. Ninety-four per cent report business as better than last year and stocks on hand are normal or low in 88 per cent. Employment has increased in 93 per cent of the factories, while there is a labor shortage felt by 66 per cent. Wages have been increased in 75 per cent of the cases, while almost the same percentage report a production increase of about 37 per cent. Sales quantities have increased about 20 per cent in 70 per cent of the reporting factories, while their values have increased on the average of 14 per cent over the values of last year.

Important Changes in Personnel at Bureau of Mines

R. B. Moore Resigns as Chief Chemist and Chief Mineral Technologist to Be Succeeded by Samuel C. Lind

RICHARD B. MOORE, well known for his work as chief chemist of the United States Bureau of Mines, is resigning his post to take effect on June 1. He is to go into commercial work with the Dorr Co., engineers, of New York, where he is to be in charge of that company's development work and is to act as consulting engineer in certain of the company's projects. His resignation follows 11 years of service at the bureau. Dr. Samuel C. Lind is to be his successor.

Dr. Moore is 58 years old. His education has included work at University College, London, under Sir William Ramsay, a B.S. degree at Chicago University, from which institution he went to the University of Missouri as an instructor. In 1905 he became professor of chemistry at Butler College, Indianapolis, where he remained until 1911. In 1916 the University of Colorado bestowed on him the honorary degree of Doctor of Science. Perhaps his most notable work at the bureau has been in connection with the production and purification of the rare gases, especially helium.

Photo by Harris & Ewing
SAMUEL C. LIND

Dr. Lind, who succeeds him, has also had very thorough training in scientific work and extensive experience in the work of the bureau. His education included study at Washington and Lee University, a degree at M.I.T., a Ph.D. from Leipzig, after which he worked at the University of Paris and the Radium Institute of Vienna. When he entered the Bureau of Mines as physical chemist, he was acting as assistant professor of chemistry at the University of Michigan. This was in 1912. Dr. Lind, at present, is in charge of the bureau's rare and precious metals experiment station, at Reno, Nev. His chief work has been on radio activity, radium extraction and measurements; the influence of radiation on chemical action; kinetics of chemical reaction; and the relations of gaseous ionization to chemical action. He is likewise the inventor of the well-known interchangeable electroscope which bears his name.

A.C.S. Invited to Washington

The Washington Chemical Society voted on May 10 to invite the American Chemical Society to hold its 1924 spring meeting in Washington. It is hoped that this session of the society can be made unusually successful because of the expected large attendance at so favorable a location. Since the society has received no other invitations for that meeting, it is expected by Washington chemists that this invitation will be accepted.

Anti-Dumping Order Issued

The Treasury Department has issued an anti-dumping order against calcium carbide imported from the province of Quebec, Canada, having received information that this product is being sold or is likely to be sold at less than its fair value, to the detriment of domestic producers. The duty on calcium carbide is 1 cent a pound. In accordance with the order under the 1921 anti-dumping law, collectors will assess additional duty on importations from Quebec sufficient to bring the total cost to a fair value.

Michigan to Have New Chemical Engineering Laboratory

With the opening of the fall term at the University of Michigan, that institution is to be equipped with its new engineering building, which will include one of the finest chemical engineering laboratories in the country. The equipment includes adequate experimental apparatus for work on evaporation, distillation, gas absorption, filtration, drying and cystallizing, as well as on stirring and mixing.

With its new facilities, the school is much better fitted for graduate work than it has been in the past. As a result several specialized groups of graduate courses are to be given, including gas engineering, metallurgy, organic industries, pulp and paper and general manufacturing.

Ford Buys Garnet Quarry

Henry Ford's latest purchase is a New Hampshire plant for the quarrying and finishing of garnet for use in the automobile manufacturing industry as a polishing agent.

Calendar

The following important technical meetings are scheduled for the immediate future:

AMER SOCIETY MECHANICAL ENGRS.
Montreal, May 28-31

CANADIAN INSTITUTE OF CHEMISTRY
Toronto, May 29-31

SOCIETY OF CHEMICAL INDUSTRY
Canadian Section
Toronto, May 29-31

AMER. ASSN CEREAL CHEMISTS
Chicago, June 4-9

AMER LEATHER CHEMISTS ASSN.
White Sulphur Springs, W. Va.,
June 7-9

NAT'L FERTILIZER ASSOCIATION
White Sulphur Springs, W. Va.,
June 11-16

NATIONAL LIME ASSOCIATION
New York City, June 13-15

SOCIETY FOR STEEL TREATING
Eastern Sectional Meeting
Bethlehem, Pa., June 14-15

AMER. INST CHEMICAL ENGRS.
Wilmington, Del., June 20-23

AMER. SOC FOR TESTING MATERIALS
Atlantic City, June 25-29

France Seizes Four German Dye Plants

Outcome of Latest Move May Have Great Significance—I. G. Now Under French Control

France has taken a big bite into the "Interessengemeinshaft" (I. G.), or German chemical trust. Four of Germany's largest dye plants have been seized. These are said to represent from 50 to 90 per cent of the entire dye output of the trust. The numerous dispatches received from the Ruhr are somewhat conflicting in detail. It is not clear what disposition is to be made of the plants seized. One report states that the time of occupation will be only long enough to seize and remove available dyestuffs which are due France and Belgium. The New York *Tribune* states, however, that "the seized factories, in accordance with the terms of the treaty, will not be turned back to Germany until the default on dye payments has been cleared up through future negotiations—a development which by no means appears imminent."

The four plants that have been seized are the Badische Anilin und Soda Fabrik, near Ludwigshafen, said to employ 40,000 workers; the Kalle Chemical Works at Biberich-on-the-Rhine; the Hochster Farbwerke, formerly the Meister Lucius & Brüning concern; and the Weiler-ter-Meer works at Urdinge, near Duisberg. The laborers on duty at the plants were allowed to leave but none was allowed to enter.

Since Germany's attitude has been disclosed on the réparation settlements question, through the note of May 2, the French and Belgians are gradually tightening their grip on the occupied areas. If German labor is unavailable in the Ruhr, France hopes to make up the shortage by imported workmen. For several days past Italians have been entering the area in large numbers.

Production of Carbon Black Becomes Political Issue in Louisiana

At Present Production Is Permitted Under Certain Regulations—Change in Administration May Ban Industry From the State

A GUBERNATORIAL CAMPAIGN is opening in Louisiana. One of the issues apparently is to be the attitude of the state toward the carbon black industry. The Monroe gas field in that state, described by the Bureau of Mines as the most extensive ever discovered in the country, now is the principal source of carbon black in the United States. The Monroe field is so isolated that no use has been found for this great gas supply other than the manufacture of carbon black, with its incidental recovery of gasoline and some small use for local fuel purposes. There has been much discussion of proposals to pipe this gas to New Orleans, but as the distance is in excess of 300 miles and the crossing of the Mississippi River is involved, the feasibility of the project has remained in sufficient doubt to prevent the financing of the project.

The present state administration in Louisiana instigated careful studies of the situation, to which the U. S. Geological Survey and the Bureau of Mines contributed importantly. As a result of those studies it was deemed best to permit the manufacture of carbon black under certain regulations. This policy now is being assailed and one of the candidates for Governor is expected to advocate that the industry be banned from the state.

It is declared that the fifteen carbon plants in the Monroe field are using 1,380,000,000 cu.ft. of gas a day. It is contended that the profits of these fifteen factories aggregate $3,000,000 a year, practically all of which goes out of the state. It is argued that the benefit to Louisiana from this industry is practically negligible and that on the other hand the extinction of the gas field is threatened.

The opposition to the manufacture of carbon black insists on basing its claims of inefficiency and waste on a quantitative standard. Sight is lost of the fact that carbon black is a complex and highly essential pigment, contributing perhaps as much to the pleasure and needs of the people in Louisiana through its use in the rubber, printing and other industries as it would were it made available to them in the form of fuel. Since the losses of long transmission would be great, the efficiency of Monroe field gas at the burner in New Orleans probably would not be much greater than that at the carbon black factories. Since the pipe line to New Orleans or other centers of population is still a vision and very likely never will be realized, the friends of the carbon black industry in Louisiana are pointing out that to ban that utilization of this resource would mean that no use whatever would be made of the gas. As the presence of gas is regarded as the best clue to the occurrence of oil, it is certain that active drilling in the field will continue. Under such conditions it never has been found practicable in any gas field to attempt to conserve the supply under ground awaiting the development of the so-called higher uses.

Strength in Paper Markets

Very firm conditions exist in the paper and pulp industry. A review of the industry by the American Paper and Pulp Association says that the paper manufacturers, in the face of the heaviest demand ever known in some branches of the industry, are not taking advantage of the increasing cost of raw materials and of labor to increase prices. In one important branch of the industry, for example, prices are 98 per cent higher than in 1914, but costs are 101 per cent higher.

The basic strength of the paper markets in general is indicated by the fact that there seems to be no speculative demand. The orders being received are strictly to meet pending requirements. Boxboard mills are sold ahead for three months, newsprint is in unprecedented demand, with prospects of still greater demand, orders for wrapping are in excess of production, and in such food-protective specialties as parchment and waxed paper deliveries are from three weeks to two months behind.

Increased Output of Acetate of Lime and Methanol

Production of acetate of lime in March was 15,569,000 lb., as compared with 13,894,000 lb. in February. For the first quarter of the year production was 46,007,000 lb., which compares with 44,171,000 lb. for the last quarter of 1922. These figures were compiled by the Department of Commerce, through the Bureau of the Census, in co-operation with the National Wood Chemical Association. Methanol production in March is placed at 91,273 gal., as against 85,105 gal. in February. For the first 3 months of the year the output of methanol reached a total of 2,498,134 gal., which represents an increase of 55,506 gal. over the production for the last quarter of 1922.

Final Program of A.I.C.E.

Local Committee of American Institute of Chemical Engineers Announces Technical Program and Social Features of Wilmington Meeting

THE fifteenth semi-annual meeting of the Institute will convene at the Hotel du Pont, Wilmington, Del., on June 20. Registration will begin at 8 a.m. and the technical program will follow closely. Four sessions of technical papers will include the following:

"Activated Carbon, Its Evaluation and Uses," Frederick Bonnet, Jr.

"The Properties of Activated Carbon Which Determine Its Industrial Applications," N. K. Chaney, A. B. Ray and Ancel St. John.

"The Abatement of Industrial Stenches by Activated Carbon," N. K. Chaney and A. B. Ray.

"The Capillary Theory of Adsorption From Solution With Silica Gel," W. A. Patrick.

"The Refining and Recovery of Petroleum Products by Silica Gel," E. B. Miller.

"Hydro-Electric Development in the Pacific Northwest," C. A. Newhall.

"Synthetic Ammonia From Byproduct Hydrogen," Charles O. Brown.

"Oxidation of NO to NO_2," W. A. Patrick.

"The Sulphur Industry," C. A. Newhall.

"Laboratory Corrosion Tests," W. S. Calcott and J. C. Whetzel.

"Materials of Construction for Chemical Apparatus," Harold F. Whittaker.

"Acid- and Abrasion-Resisting Metals and Materials," W. E. Piper.

"Modern Methods of Metal Protection and Finishing," L. E. Eckelmann.

"The Literature of Chemical Corrosion," A. E. Marshall.

"Action of Fullers Earth on Vegetable Oils," David Wesson.

"Automatic Fractionating Columns," W. A. Peters, Jr.

"The Rate of Absorption of Hydrochloric Acid Gas in the Tyler Vitreosil System," H. E. Fritz and James R. Withrow.

"The Theory of the Design and Testing of Gas Absorption Apparatus," E. M. Baker.

"Calculation of Vapor Recompression Evaporators," L. A. Pridgeon.

"Economic Value of Chemistry in Industry—A Study of the Census of Manufactures, 1919, and of Foreign Trade, 1921," R. K. Strong.

The members and guests of the Institute will be entertained at a reception given by Mr. and Mrs. C. L. Reese on Wednesday afternoon and at the theater in the evening. An opportunity for inspecting the conservatories of P. S. du Pont and a supper at the home of Irenee du Pont will be among the courtesies extended to the visitors.

Trips through the famous Jackson laboratories of the du Pont Co., the Jessup & Morse Paper Co., the Bond Corporation cork plant and the Joseph Bancroft cotton-finishing plant will be features of the technical program.

Washington News

Spain Excludes U. S. From Favored Import Rates

Cable advices from Commercial Attaché Cunningham at Madrid state that a Spanish decree of April 30 grants the benefit of preferential rates of the import tariff to Honduras, Hayti, Dominican Republic and Panama, thereby according them the same treatment as is given other American republics by previous legislation. The favored rates are not extended to include the United States, Canada and Brazil. According to unofficial advices from Spain, all goods from the United States imported into Spain after Nov. 5 will be subject to materially higher duties than are now in effect. Efforts are being made to procure an agreement whereby materials and manufactured goods from this country will be admitted into Spain on a more favorable basis, but the higher import duties on many materials originating in Spain, as put into effect by the new tariff act of this country, makes it improbable that our goods will be favored by Spanish import regulations.

United States Largest Buyer of Haitien Logwood

A report from Consul Damon C. Woods, covering the logwood industry in the Cape Haitien consular district, states that logwood held second place among the commodities exported from that district in 1922. In commenting on market conditions, the report states that logwood recovered appreciably from the depression of 1921, when the price fell to $15 per ton f.o.b. Cape Haitien, as contrasted with $40 in the summer of 1920. Of the total amount shipped in 1922, at least 90 per cent went to Newport News and Chester, Pa., for reduction into extract at the plants of large American dyewood concerns. This proportion amounted to 13,571 tons, of the declared value of $277,194.79, or an average of $17.42 per ton after deduction of the export duty of $3 per ton. Due to the lower freight rate nearly all of this logwood was carried on sailing vessels.

The logwood extract plant at Grand Riviere du Nord, in the Cape Haitien district, increased its output and exportation from 306,199 lb. of liquid extract in 1921 to 1,552,889 lb. in 1922. The declared value of the product for the latter year was $59,592. In addition the factory shipped 30,260 lb. of extract in crystallized form. The entire quantity went to the United States.

Declared exports from the three ports of the district to the United States, exclusive of returned American goods, for the years 1921 and 1922 were:

	1921		1922	
	Quality	Value	Quantity	Value
Logwood....	10,047 tons	$238,148	13,571 tons	$277,194
Logwood extr. crystals	....	....	30,260 lb.	2,092
Logwood extr. liquid	306,198 lb.	17,836	1,552,889 lb.	59,592

Thomas W. Delahanty Joins Chemical Division

Thomas W. Delahanty, a chemical engineer of New York, who recently was appointed a member of the staff of the Chemical Division of the Department of Commerce, assumed his new duties May 14. The appointment is in line with plans to increase the staff of the division under C. C. Concannon, acting chief, to meet the demands of expanding work.

Mr. Delahanty is a Cornell graduate and a member of the American Chemical Society and of the American Society of Mechanical Engineers. During the war he was inspector of powder and explosives in the ordnance department of the army and later became Lieutenant in the navy air service in charge of hydrogen gas production at Rockaway Beach, N. Y. He has had considerable experience in manufacture, import and export of drugs, chemicals and dyes through his connection with Dicks David Co., Inc., and the American Chemical Co. He came to the Chemical Division from the Ajax Rubber Co., where he had been systematizing production, control and marketing of products.

Specific Penalties for Loss of Shipping Documents

Of interest to importers was the announcement of Assistant Secretary of the Treasury Moss, made last Wednesday, to the effect that new regulations would become effective with reference to the cancellation of bonds. This refers to bonds given by importers in cases where goods reach domestic markets and where shipping documents are missing or are incomplete. In such cases the consignee obtains possession by furnishing a bond to the collector of customs, in order to guarantee the later presentaton of the necessary documents. According to the new instructions, collectors of customs are advised, in treating bonds for the production of missing documents as satisfied, to demand and collect $20 for each missing invoice not produced within 6 months, and $10 for each missing declaration of the owner or ultimate consignee not produced within 90 days from the date of entry.

Also an amount equal to the invoice value plus the duty will be collected for failure to return to the collector on demand packages subject to redelivery.

Collectors may in their discretion waive demands for the payment of liquidated damages upon the non-production of other documents governing the importation and admission of merchandise into the commerce of the United States, but when demand is made in such cases no greater amount will be collected than $20 upon any one default of the bond, without specific authority of the department.

Unfavorable Outlook for Lower Freight Rates

Senators and Representatives who have been planning to make a drive at the next session of Congress for reduced freight rates are perturbed by the prospect that such agitation will not arouse any popular enthusiasm. When prices are good, the average shipper is more interested in service than he is in the rate. On most commodities the freight rate really represents a small percentage of the selling price. When prices are hovering around the cost of production, the freight charge looks big. For that reason the agitation of railroad legislation in 1921 and early in 1922 struck a popular chord. It is believed, however, that in prosperous times there will be no general support for any legislation that would instruct the Interstate Commerce Commission to regard an amount less than 6 per cent as a fair return or to take into account other factors which would have the effect of lowering rates.

Transportation specialists in Washington agree that more efficient service is being rendered by the railroads at this time than ever before has been the case. The proportion of unfilled car orders to the total loadings is very small. This has been made possible through closer co-operation and more friendly relationships with the shippers; through the reduction to the minimum of bad-order equipment, and through the placing in service of increasing numbers of new cars.

Personals

Leon Rigole, vice-president of the Société Co-operative Graines & Huiles, Antwerp, was in New York last week.

C. A. Mace, formerly with the Butterworth-Judson Corporation, is now associated with the Tower Manufacturing Co.

Colonel Charles B. Wing, prominent paper manufacturer, died at his home in Cincinnati on May 13.

J. W. Daniels, president of the new linseed oil combine, the Archer-Daniels-Midland Linseed Co., Minneapolis, was in New York last week. According to G. H. Tomlinson, who is in charge of the New York office of the old Midland Linseed Products Co., the sales policy will not be altered in any way, and the production of "Midland" brand oil will be marketed through his office as heretofore.

F. C. Ryan, Eastern sales manager of the Shasta Zinc Co., left New York last week on a business trip, to include points in the Middle West.

American Exporters Urged to Retain Trade of Foreign Markets

Business With Markets Abroad Being Neglected, According to Reports Received by Department of Commerce

After having captured a considerable foreign trade, American manufacturers are allowing it to get away from them while they cater to the domestic market, which for the nonce is more attractive. Reports to the Department of Commerce from a large number of countries indicate that American exporters are neglecting their foreign business. Since the war upset the world's trade, the American exporter has been playing the flirt with foreign markets, as one official described it. For a time every attention will be given a foreign buyer and then without warning he will be jilted. It is feared that many markets will be lost irretrievably to the United States if the present tendency continues.

Largely as a result of fortuitous circumstance, the United States has built up an important foreign business. While favorable conditions were responsible for inducing American manufacturers to go into foreign markets, their activities in that connection represent a large investment. Not only is this investment being jeopardized by the present business policies of many exporters, but it is sealing the way against any retracing of steps when the domestic demand begins to fall off.

Officials of the Department of Commerce are urging that a fair distribution of available stocks be made among all customers. If there is to be any favoritism shown, it should be in favor of the foreign market. American consumers, once that they understand the situation, would be willing to make some sacrifice in order that foreign trade may be retained.

American manufacturers and exporters, it is pointed out, would be well advised in taking a leaf from the German book. Germany, and to a less extent England, fill foreign orders first. They are in a position to satisfy later their domestic customers if they should be displeased in securing delivery. Concrete information is at hand from a hundred sources to indicate that foreign markets are being neglected. It applies to all lines and is not confined to the chemical trade. The situation is regarded at the Department of Commerce as being of sufficient seriousness to require the most energetic efforts to remedy the situation while there still is time.

Curtis to Direct Chemical Engineering at Yale

Harry A. Curtis, now in charge of the Department of Commerce's nitrate investigation, has been appointed professor of chemical engineering at Yale University. He will undertake his new work at New Haven early in the fall, taking charge of the course in chemical engineering which was established by Yale about 3 years ago.

The work in chemical engineering at this institution is to be developed in close co-operation with both the chemistry and the engineering departments. Details of the plans for the department and the course of study will be prepared during the next few months to permit their application during the next college year. As head of the department Curtis will be active in both the scientific and technical faculties.

The nitrate study on which he is now engaged will be actively prosecuted by Dr. Curtis during the summer and probably will continue to receive his attention in a consulting capacity until this part of the government's raw materials survey has been completed.

Photo by Harris & Ewing

HARRY A. CURTIS

Dr. Curtis was graduated from the University of Colorado in chemical engineering and taught there for several years prior to 1917. He received the Ph.D. degree in chemistry at the University of Wisconsin and somewhat later was for a short time professor of chemistry at Northwestern University. For 2 years he was in government work, first as a Captain in the Ordnance Department and later as executive officer of the Fixed Nitrogen Research Laboratory, Washington. In this War Department work he was active in the design and operation of the small-scale ammonia-oxidation plant at Sheffield, Ala. More recently he has been chief chemist of the International Coal Products Co., first being in charge of research and development work at Irvington, N. J., and subsequently serving as general manager of the Clinchfield Carbocoal Corporation, South Clinchfield, Va., an International subsidiary.

News Notes

The California Section of the A.C.S. continues to provide excellent addresses at its monthly meetings. On May 11 Prof. James Kendall of Columbia gave an illustrated talk on "The Separation of Isotopes."

"The Andrew Carnegie Chair of Biochemistry" is the name assigned to the chair of biochemistry at the University of Cincinnati, according to an announcement made by Judge Rufus B. Smith, chairman of the board of trustees. With the expansion of the biochemistry department at the University of Cincinnati it is expected that Cincinnati will become the center for the study of various branches of chemistry.

A new chemical laboratory at Tufts College, Mass., comprising a large three-story and basement building, is practically completed, and arrangements are being made to dedicate the structure with appropriate ceremonies on alumni day, June 16.

Oats won't produce alcohol, although sugar can be obtained in large quantities by hydrolysis of hulls. The Forest Products Laboratory has made this finding as a result of special experiment. It is thought that this conclusion confirms the belief that many cellulosic substances which have been considered as possible sources of alcohol are actually not suitable for its production.

The second annual fertilizer conference to be held by the Connecticut Agricultural College is planned for July 11 and 12. This conference is intended primarily for manufacturers and dealers. However, several papers of interest to the consumer as well as to these groups are included in the program.

Cleveland and Akron chemists are planning a big day for May 23, when the Cleveland Chapter of the A.C.S. holds its spring meeting. During the day several Cleveland plants are to be visited and in the evening Charles L. Parsons, H. E. Howe and H. H. Dow, president of the Dow Chemical Co., are to address the society.

Non-Shellac phonograph records of simple materials and inexpensive fabrication have been developed by European manufacturers. The new process, using paper, cloth or leather as a base instead of requiring molding, makes use of rotary presses capable of turning out 50,000 per unit per day. The unit mold's capacity has been about 600 per day. Production of the new records is to begin here in the near future.

Liquid oxygen can be used to advantage in lessening blasting costs in iron, salt and other mineral mines and quarries. This explosive also has several further advantages, according to the Pittsburgh experiment station of the Bureau of Mines and $15,000 for further investigation of this use of oxygen has been appropriated for use during the coming fiscal year.

American Buyers of Goods in the Ruhr May Obtain Export License

New Regulations Define How Applications Must Be Made—German Firms Authorized to Make Deliveries on Sales Made Prior to Feb. 20

LAST Wednesday the Department of State issued a statement, in which was outlined the method to be followed by American importers, in securing deliveries of goods which they had purchased from the Ruhr section of Germany. The statement sets forth that the method of procedure in securing export licenses is not as simple as it is desired, but represents such concessions as have been granted to date on the part of the German authorities and from the occupying forces. It is held that American buyers will receive considerable relief by observing these regulations and directions.

"American buyers intending to apply for export licenses for goods in occupied Germany must address their applications to the Rhineland High Commission at Coblenz, stating the date of contract, quantity and character of goods, the value of order, name of German supplier and submit evidence showing that contract was made prior to Feb. 1 and that payment has been made either in whole or in part. A copy of the contract should accompany the application.

"However, the authorities in occupation stipulate that applications must be accompanied by a statement covering the American interest in the shipment. Accordingly, until further notice, American buyers should first submit the application direct to the American Embassy in Paris or Brussels, which will issue the statement required and forward it with the application to the American Consul at Coblenz, who in turn will present the application to the High Commission for approval. When the application is returned, the Consul will, upon request, turn it over to the American buyer's agent or representative, who should then make all arrangements with appropriate licensing office for delivery of the license and payment of export tax, to the authorities in occupation.

"The department is informed that the authorities in occupation on May 1 put into force an export tariff based on the German export tariff of 1921 instead of the 10 per cent ad valorem tax which has been temporarily collected and, furthermore, that the time for receiving applications from American buyers for contracts made previously to Feb. 1 has been extended for an indefinite period. However, American buyers are urged to expedite their applications as much as possible. The department also understands that German firms are now authorized by their government to deliver goods involved in commercial transactions made prior to Feb. 20, provided they have first obtained a German export license.

"In negotiating, on behalf of American commerce, with the various governments concerned in this matter, it has been the aim of the Department of State to endeavor to obtain for American traders the same facilities granted to traders of other countries and at the same time to find a way out of the present deadlock of commerce, whereby, through the modification of conflicting regulations and the elimination as far as possible of official interference, the movement of American-owned goods for export out of occupied Germany could actually be accomplished."

Federal Specification Board Officials Named

Dr. George K. Burgess, new director of the Bureau of Standards, has been named by the President as chairman of the Federal Specification Board. In this office he succeeds S. W. Stratton, formerly director of the bureau.

N. F. Harriman, who has been acting chairman during the interim, is named as vice-chairman and technical secretary of the board, in charge of all administrative and routine matters and supervision of technical committee work. Mr. Harriman is located at the Bureau of Standards.

Manganese Exports From Brazil

Total exports of manganese from Brazil in 1922 were 340,706 tons, an increase in quantity over 1921 exports and a decrease as compared with 1920, according to a report from Commercial Attaché W. L. Schurz at Rio de Janeiro. Heavy exports were made to the United States, the message states.

Figures on total manganese exports for 5 years, in gross tons, with the average price per ton are given as follows:

1922, 340,706 tons, $65; 1921, 275,694 tons, $83; 1920, 453,737 tons, $88; 1919, 205,725 tons, $82; 1913, 122,300 tons, $22.

Quiet Market for Fertilizers in France

The French fertilizer market is calm, according to a cable from Commercial Attaché Jones to the Department of Commerce dated May 13. April deliveries of nitrate of soda were 53,000 tons, imports were 37,000 tons and stocks on hand 20,000 tons. Little business is being done in other fertilizers. The price of turpentine fell to 600 francs, the market being unsettled. Raw materials of naval stores are being gathered.

Trade Notes

Stocks of flaxseed at Minneapolis on May 12 were placed at 10,263 bu., which compares with 6,885 bu. the week previous and 69,829 bu. on the corresponding date a year ago.

The Department of Commerce announces that the value of products of establishments engaged primarily in the distillation of common or ethyl alcohol and other liquors, whether sold as such for industrial or medicinal use, or in a denatured form, amounted to $28,789,000 in 1921, as compared with $31,854,000 in 1919, a decrease of about 10 per cent.

The Endicott-Johnson Corporation officials have been in St. Louis inspecting various properties with a view to locating a large warehouse there.

The M. S. Chemical & Drug Co. of Brooklyn, N. Y., has increased its capital stock from $5,000 to $250,000.

The Archer-Daniels Linseed Co., 29th Ave., Minneapolis, Minn., manufacturer of oil products, has been reorganized as the Archer-Daniels-Midland Co. A charter has been taken out under Delaware laws with capital of $10,625,000, and plans are in progress for general expansion in plant facilities for the production of vegetable oils.

Governor Gifford Pinchot of Pennsylvania has signed a bill recently passed by the Legislature, regulating the sale of caustic acid, alkali and chemical or mineral preparations designed for domestic or agricultural service. The bill requires that all containers used for such materials be labeled with the name and address of the manufacturer, and the word "poison."

The Rubber Controller for Ceylon has announced that a maximum of 36,020 long tons of Ceylon-produced rubber may be exported from Ceylon during the year Nov. 1, 1922, to Oct. 31, 1923.

The steamship "West Prospect" arrived at San Francisco on May 14, from Manila, with a cargo of 2.259 tons of copra.

E. Bright Wilson has been appointed equity receiver for the Druggists' Commercial Alliance, Inc., 250 Hudson St., New York, in an action filed by the Mifflin Chemical Corporation.

Officials of the International Paper Co. have denied reports that the company is involved in negotiations for a merger with Canadian interests which would combine a half dozen plants operating on the St. Maurice River near Quebec.

Bush, Beache & Gent, Ltd., of London, announces that the company is now entirely British owned. It is removing shortly to larger offices at 24 Monument St., London, E. C. 3.

White Arsenic Makes Gold Mining Profitable

New Plant Treating Gold-Bearing Concentrate at Montana Mine Yields 100 Tons of As_2O_3 Per Month—Sold at 14½c. Per Lb., f.o.b. New Jersey

ON APRIL 15 the Jardine Mining Co. removed 75 tons of crude oxide of arsenic from the kitchens of its newly built plant at Jardine, Mont. This was the first product from the plant, which had been in operation for about 30 days. The mines of the Jardine company are on the edge of Yellowstone National Park, 6 miles from Gardiner, the nearest railroad point. They have been worked for gold for many years. The ore is low grade, however, and the recent demand for arsenic offered a welcome opportunity to realize a profit from the large content of arsenopyrite in the gold ores.

The special correspondent of *Engineering and Mining Journal-Press* in that vicinity reports that as a consequence of the high price of arsenic, plans were made in December, 1922, to treat the concentrate and recover the arsenic at the mill. Fortunately, the large mill building formerly used as a cyanide plant was in good condition. A few tanks were removed, the building was remodeled, and the new equipment was rapidly installed. A reverberatory furnace, connected with a dust chamber, and a series of kitchens 6x8 ft. in section and 180 ft. long, were built. These were connected to a large stack, the top of which is 250 ft. higher than the furnace. Construction work was finished and the plant was operating on March 17, just 2 months from time it was started. The cost of plant, including building alteration and equipment, was $12,000.

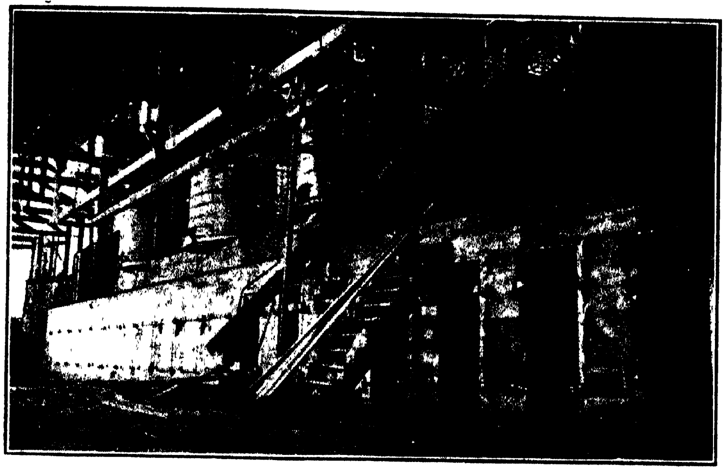
The first time the concentrates are treated the reverberatory furnace is fired with ordinary mine-run coal. The arsenic volatilizes and the fume is conducted through the dust chamber and thence to the baffled kitchens, where the arsenious oxide is deposited. This product is not white; accordingly it is stored until enough has been accumulated for refining. It is then put through the same process except that a coke fire is used in the reverberatory instead of a coal fire.

The concentrate as received from the mill averages 38 per cent arsenic and contains from 2 to 3 oz. in gold per ton. At the present time the capacity of the arsenic plant is limited to 100 tons of oxide per month.

Shipped to New Jersey

The first car of calcined concentrates was shipped from Gardiner on March 29 to the East Helena smelter. The first shipment of refined white arsenic was contracted for by W. F. B. Berger, representing the Chipman Chemical Engineering Co. The price agreed upon was reported to have been 14½c. per lb. f.o.b. Bound Brook, N. J.

The large smelting companies have been producing white arsenic as a by-product for years, but this is probably the first venture at producing it as on a commercial scale by an independent mining company.



ARSENIC KITCHENS BUILT IN THE OLD CYANIDE PLANT AT THE JARDINE MINE

Leather Chemists to Meet at White Sulphur, W. Va.

The convention of the American Leather Chemists which is to be held at White Sulphur, W. Va., June 7-9 is to include features which will be of great interest. These embrace a wide field, including among others two papers on chrome tanning, one on tannin and several on the use of oil in leather fabrication. Dr. Allan Rogers will give a unique talk, illustrated by moving pictures, on leathers of marine origin. F. M. Moffat, president of the Tanners' Council, plans to be present to address the association.

Advisory Committee Expanded for 1923 Exposition

Chemical Exposition plans are being formulated for the 1923 show, which is to be held at Grand Central Palace, New York, during the week of Sept. 17 to 22, inclusive.

The advisory committee which aided in conducting last year's exposition has been expanded, and in addition to the former twenty executives and technical men now includes the following members from the sales and production departments of the chemical and chemical equipment manufacturers: John W. Boyer, of the Mathieson Alkali Works; Dr. Charles L. Reese, of E. I. du Pont de Nemours & Co.; Percy D. Schenk, of the Duriron Co.; Milton Kutz, of the Roessler & Hasslacher Chemical Co.; W. E. Moore, of the New Jersey Zinc Co.; T. C. Oliver, of the Chemical Construction Co.; R. Gordon Walker, of the Oliver Continuous Filter Co.; Williams Haynes, of *Drug and Chemical Markets*; H. J. Schnell, of the *Oil, Paint and Drug Reporter*.

Alabama Exporting Large Amounts of Pitch

According to advices coming from Birmingham, Ala., a number of plants in that section are selling pitch in large quantities to European governments and private firms. One company at Ensley is reported to have closed.

The Semet-Solvay Co. of Ensley has just closed a deal with the Italian Government for 5,113 tons of pitch for $60,000. This is but a small part of a movement of pitch that has been going to Europe during the past few months. In all it is estimated that from 40,000 to 50,000 tons has been shipped to Europe since Jan. 1, 1923.

About 35,000 tons of pitch had been accumulated by another company. All of this has been shipped to France, Italy and other countries, having been sold mostly in 5,000-ton lots.

Before the world war much pitch was shipped from the Birmingham district to European countries. During the war the shipments ceased. It has only been since Jan. 1 of the present year that these shipments have been revived. During the war piles of pitch at a number of plants at Bessemer and Fairfield grew very large, and it is out of these piles that many shipments have been made.

European manufacturers are using this pitch in making briquets, which are burned as fuel and are very valuable where coal is scarce or high.

One large producer has recently perfected a high-grade coke, which is manufactured out of this pitch by putting it through a beehive coke oven. This gives a coke of 98 per cent pure carbon, and sells for several dollars more per ton than ordinary coke.

It is estimated that from now on Birmingham pitch will continue to move to Europe at the rate of from 6,000 to 8,000 tons per month, even after the present accumulation is exhausted.

Facts and Figures That Influence Trade in Chemical Products

Market Conditions

Current Prices
Imports and Exports
The Trend of Business

Prices for Chemicals Continue to Show Downward Tendency

Arsenic and Calcium Arsenate Sell at Lower Levels—Imported Copper Sulphate Weak—Prussiates Inactive and Decline in Price—Permanganate of Potash Lower—Denatured Alcohol Advanced in Price—Acetate of Lead Higher

THE market for chemicals was easier during the week. A few items, notably acetate of lead and alcohol, were marked up in price, and many of the important chemicals held a steady position, yet the general tone as a whole was easier. Imported materials have led the way in the downward movement and are relatively weaker than chemicals of domestic origin. In part this is due to lack of confidence in the position of foreign and in part to arrivals from abroad at a time when buyers were not prominent with the consequent result that prices were lowered to move stocks and thus avoid carrying charges. There seems to be a hesitancy on the part of consumers to take on fresh commitments and the market is not in a position to encourage speculative buying from non-consumers. Basically many selections are in a firm position but the influence of foreign markets and the attitude of buyers is expected to be a prominent factor in regulating values.

Arsenic holds a very prominent place in the present market. Views regarding prices for the next three months vary with well posted members of the trade holding that declines will be maintained only if imported makes come on the market in large volume. Estimates on domestic production of arsenic have been lowered but this has very little bearing on the market for nearby positions. It is evident, however, that demand has fallen off with the coming of lower prices and the same holds true for calcium arsenate.

Buying of caustic soda for export has ceased to be active and reports are heard that prices would have to be lowered materially to meet the views of foreign markets. As a result prices f.a.s. New York are easy and concessions could be obtained if actual business was in sight. On the other hand bichromates are firmly held and production has been reduced due to scarcity of labor. Most of the acids likewise are firm with some selections sold ahead and very little to be had in the open market.

The prospect of securing chemicals from the Ruhr, that is on purchases made prior to Feb. 1 and possibly to Feb. 20, were brighter as the result of an announcement from the Department of State that arrangements had been made with the authorities in Germany and with the authorities of the occupying forces, whereby shipments would be made, if a prescribed method of procedure were followed in securing export licenses.

Acids

Acetic Acid—Consuming demand is variously reported but in general new business appears to be along quiet lines, with export slowed up by the high prices in effect. Some of the largest consumers are covered by contracts placed at prices below those now quoted in the open market. Current quotations are on a basis of 3.38c. per lb. for 28 per cent and 6.75c. per lb. for 56 per cent. On glacial prices vary according to seller with round lots quoted at 12c. to 12.78c. per lb.

Boric Acid—Sellers are reported to be competing keenly for business and values have not reacted from the recent decline. Increased output also is credited as being a factor. Offerings are available at 10½c. per lb., in bbl. and 11½c. per lb., in kegs.

Chromic Acid—Steadiness in price has been the outstanding feature to this acid for a long time. Consuming interest is sufficient to prevent accumulations, without causing any upset to values. The technical grade is held at 39c. per lb., in drums and 98 per cent at 40c. per lb.

Citric Acid—Reports from foreign markets still indicate firm prices abroad and this has a steadying influence on the market in general. Spot holdings, however, have been subject to some fluctuations according to seller with offerings heard at 51½c. to 52½c. per lb. Domestic goods holds at 49@50c. per lb. with offerings fairly ample.

Lactic Acid—Imported offerings are said to be in fair demand with prices largely nominal. Home makes are finding a good outlet in consuming trades with prices on a steady basis of [illegible]@6c. per lb. for 22 per cent light and [illegible]@5c. per lb. for 22 per cent dark.

Muriatic Acid—Producers are still well sold ahead and the scarcity of stocks gives a strong tone to the market. Good call is reported for contract deliveries and this leaves but little to be had on new accounts. Quotations are given at 90c. to $1 per 100 lb. for 18 deg. and $1.75@$2 per 100 lb. for 22 deg.

Oxalic Acid—Prices for domestic remain firm at 13½c. per lb., f.o.b. works with smaller lots commanding higher prices. Demand, while not active, has been fairly good. Imported is not in large supply but prices do not appear steady and sellers are open to bids with 13½c. per lb. given as representing the market.

Tartaric Acid—Imported was easier in tone and 36¾@37c. per lb. was quoted for prompt. Trading was not active. Domestic grades are moving regularly against contracts with very little offered in the open market. Prices for the latter hold at 37½c. per lb.

Potash

Bichromate of Potash—The general asking price of producers is 11½c. per lb., f.o.b. works, although some makers are willing to deliver at that price in places near by works. There has been a fair call for moderate sized lots and with an absence of competitive selling, values are well maintained.

Caustic Potash—Sales of domestic have been made at 9c. per lb., works, and this is the inside price heard for such offerings. Imported sold at 7½c. per lb. early last week, and eagerness of holders to move stocks gave a weak appearance to the market. As low priced stocks were reduced, prices recovered slightly and 7¾c. per lb. was asked for spot and shipment. In fact shipment was quoted up to 8c. per lb. and prices depended on seller.

Carbonate of Potash—Stocks of 90-95 per cent are still held in the local market, with prices low in comparison with quotations for lower grade material. It was possible to do 6½c. per lb. For 80-85 per cent asking prices were 7c. per lb., with a possibility that 6¾c. per lb. could be done. Hydrated was in fair demand at 7½@7¾c. per lb.

"Chem. & Met." Weighted Index of Chemical Prices

Base — 100 for 1913-14

This week	177.66
Last week	177.69
May, 1918	270.00
May, 1919	248.00
May, 1920 (high)	280.00
May, 1921 (low)	143.00
May, 1922	159.00

An easier situation in spot barium chloride brought down the week's index number 3 points. The major items in the list scarcely moved so far as prices were concerned.

Chlorate of Potash—Offerings of imported chlorate could be picked up at 7¾c. per lb. and attempts to advance prices resulted in withdrawal of buyers. There is a steady movement of domestic with the price holding steady at an inside figure of 8½c. per lb., works, for powdered or crystal.

Permanganate of Potash — Lower prices have prevailed in this market and the impression is gaining that still lower prices are to follow. The general asking price for spot material was 19c. per lb. Consumers are slow to take hold and prices for shipment are purely nominal, as no interest was taken in forward positions. Some consumers say that a 14c. per lb. level will be reached before the decline will be checked.

Prussiate of Potash—While 70c. per lb. was asked for red prussiate, it was difficult to interest buyers at that figure and on firm bids it was reported that 68c. per lb. would find sellers. Yellow prussiate likewise was easier and 36c. per lb. was given as the price at which sales were made.

Sodas

Soda Ash—The market is quiet as far as new business is concerned but contract withdrawals are holding up well and this is absorbing a large part of production. Prices are holding on a steady basis with quotations for light ash at $1.20 per 100 lb. in bags, carlots at works and $1.40 per 100 lb. in bbl. These are contract prices and on new orders for prompt shipment a slight advance is asked. Dealers have quoted as low as $1.75 per 100 lb., with a range upward on a quantity basis.

Bichromate of Soda—Underlying conditions have not changed for the better, and prominent producers are holding out for 8½c. per lb. at works. The spot market is quiet but 8½c. per lb. is asked, and while reports are still heard to the effect that odd lots can be picked up at 8¼c. per lb., this is by no means an open quotation.

Caustic Soda—The falling off in export buying has had a dampening effect on prices, in spite of attempts of producers to maintain values. Shipments to foreign markets are noted against old orders, but demand for June forward is very dull and according to reports $3.25c. per lb. could be done on some makes, although prices are generally quoted at 3.30@3.35c. per lb., according to brand and seller. Domestic consumption is fairly large, based on the movement from producing points. Quotations for domestic use are 2½c. per lb., basis 60 per cent, carlots, f.o.b. works. Spot offerings are held at an inside price of 3½c. per lb., with the usual range for smaller amounts.

Fluoride of Soda — The advance in price of a short time ago served to restrict trading, and values have eased off both on the part of imported and domestic grades. Freight rates play an important part in dividing demand for the two grades, with imported cheaper along Atlantic coast points. Prices for imported are 9@9½c. per lb., while domestic is held at 10½c. per lb. and upward on a quantity basis.

Nitrate of Soda—The announcement of a new schedule of prices for shipments from Chile, as reported last week, has had no influence as a market factor. In the spot market $2.60 per 100 lb. is given as the asking price, but resale offerings are rather numerous, especially at southern points and this causes some shading. Interest is not keen either for spot or shipment. The new prices are on a basis of $2.45 per 100 lb. for July, August and September; $2.47½ per 100 lb. for October; $2.50 per 100 lb. for November; $2.52½ per 100 lb. for December; $2.55 per 100 lb. for January; $2.60 per 100 lb. for February; $2.62½ per 100 lb. for March to June inclusive. Estimates on consumption of nitrate for the year, to end June 30, place the total in excess of 2,100,000 tons and the visible supply is placed at 1,150,000 tons.

Prussiate of Soda—A buyers' market has prevailed with prices weak. Spot holdings have shown wide fluctuations, according to seller. Some reports credit sales at 16½c. per lb. and up to 17½c. per lb. is asked. Buyers are interested only when concessions are granted and slow consuming demand is largely responsible for the present weakness. Imported for shipment is quoted at 16½@17c. per lb., with prominent domestic producers not yet ready to quote on anything but May deliveries.

Miscellaneous Chemicals

Acetate of Lime—Reports on production show that the domestic output for the first quarter of the year was larger than for the last quarter of 1922. The position of raw materials, however, is firm and the higher selling price recently inaugurated is being adhered to. Asking prices are 4@4.05c. per lb.

Arsenic—Demand for white arsenic is none too active. The fact that some domestic producers are supplying consumers at prices under those quoted in the open market is taking away interest in imported grades. It is generally held however that prices will hold fairly steady for the present unless imports become larger than is now expected. Some producers have offered prompt shipment at 13½c. per lb., but there were offerings of prompt from Canada at 13c. per lb. with June shipment at the same price. For June, domestic material is offered at 12½c. per lb. In the spot market prices ranged from 14¾c. to 15c. per lb., but it was difficult to arouse interest at those levels. Some reports say that sales for delivery into 1924 have been made at 9c. per lb., but other reports say there is no interest in distant positions.

Calcium Arsenate — Buying interest has become less active and consumers evidently are influenced by the lower prices which have come out recently for arsenic. Sales of calcium arsenate are reported to have gone through at 16c. per lb. although 17c. per lb. is the figure asked in many quarters. A considerable quantity of arsenate was damaged by fire last week but this had nothing more than a passing effect on the market.

Copper Oxide—Demand has been active throughout the season and stocks have been held at low levels. Some producers are using their entire output to take care of contract deliveries and are unable to quote for nearby shipment. With offerings difficult to locate, prices are little better than nominal. with prices of 20@21c. per lb. heard as representing sellers views.

Copper Sulphate — Domestic makes are offered at 6c. per lb. for large crystals and 5.90c. per lb. for small crystals. Demand is reported to be fair but not active. Imported grades were very weak and sales are said to have been made at 5½c. per lb. The lower prices have not succeeded in stimulating business to any marked degree and the trend of values is uncertain, depending on the volume of imports.

Cream of Tartar—Domestic makers held out for 26½c. per lb., while on the imported there were sellers down to 25½c. Demand showed no improvement, and, despite the recent uplift in the acid, prices were rather unsettled in some directions.

Lead Acetate—With the seasonable demand about to come in producers of lead acetate advanced the market ½c. per lb. The revised trading basis follows: White crystals, bbl., 14@14½c.; white, broken, 13½@14c.; white granular, 13¾@14¼c.; brown, broken, 13@13½c. per lb. Less than a fortnight ago there was much talk of a higher market, but the weakness in the metal held prices in check. The higher cost of acetic acid was one of the reasons given out for the uplift in prices.

Tin Oxide—The market for tin suffered another decline, but late in the week the metal developed a firmer tendency and producers of tin oxide saw no good reason for lowering prices. Up to the close 50c. represented the general asking price.

Denatured Alcohol Up

Leading producers of denatured alcohol announced an advance of 2c. per gal. on all grades. Demand was described as fair, but with competition not so keen, the market presented a better feeling from the seller's point of view. The No. 1 special closed at 35c. per gal. in drums, and 41c. per gal. in barrels, carload lots. Completely denatured, 188 proof, formular No. 1, was raised to 43c. per gal. in drums, and 49c. per gal. in barrels. Ethyl spirits closed unchanged on the basis of $4.70 per gal. for the 190 proof, U. S. P. Methanol also was unchanged, first-hands quoting on the basis of $1.18 on the 95 per cent. Production of methanol in March was placed at 831,784 gal., against 733,179 gal. in February and 933,171 gal. in January.

Coal-Tar Products

Competition in Salicylates Unsettles Prices—Spot Phenol Quiet—Flake Naphthalene Sells at 9c. on Spot; Crude Easier

AT THE close of the week prices named for the salicylates showed a wide range. The decline in the market was not general, several large factors refusing to meet the cut announced early last week and, according to some traders, it was not possible to purchase round lots at the lower levels in all instances. Talk in the trade had it that a "price war" was the cause of the sudden shift in the position of certain makers. With no important change in the market for phenol, traders seemed to be at a loss for any other reason for the decline. Of course, there is a possibility that, with demand less active and prospects for cheaper phenol in sight, producers who led in the decline saw no good reason for maintaining prices any longer.

The reported seizure by the French of several large German coal-tar products plants attracted attention in trade circles here, but in the absence of more definite information operators suspended judgment. With sufficient tariff protection manufacturers in this country are no longer so anxious about developments abroad. It is pointed out that the American coal-tar products industry has made rapid strides toward recovery from the severe slump witnessed about 2 years ago.

Importations of naphthalene continue, but virtually all of the crude arriving is moving into manufacturing channels. New prices on domestic ball and flake naphthalene have not yet been named. Spot flake was barely steady. Phenol settled at 54@55c. on spot, with trading quiet all week. Benzene in other than motor grades appeared in largest supply, but prices showed no quotable change.

Benzene—Reports on the state of trade were rather conflicting last week. Several handlers took the stand that business was not so good as at this time last year, yet prices pointed to a fairly steady market. Sales of the 90 per cent grade, for prompt shipment, went through at 30c. per gal., carload lots, in drums. Leading factors say that there is no accumulation in stocks of motor benzene and that indications point toward a steady market for some time to come.

Creosote—Another bulk shipment of creosote oil arrived from abroad consigned to wood preservative plants. What really interested traders was the receipt of several shipments of creosote oil fit for disinfectant manufacture. The market for the 25 per cent grade held at 30c. per gal. in tanks and 35c. per gal. in drums.

Cresylic Acid—The demand was inactive and prices were unsettled, imported 97 per cent, pale, being available at $1.25@$1.30 per gal., in drums, while on the 95 per cent, dark, there were sellers at $1.15 per gal. Domestic production has been augmented, but actual offerings remain light owing to the sold-up condition of leading makers.

Naphthalene—During the past week 1,440 bags of crude naphthalene arrived at New York, mostly from German ports. The market for crude was easier and nominal quotations on fair quality goods ranged from 3¼@3½c. per lb. c.i.f. New York. Flake on spot sold at 9c. per lb. On ball naphthalene the "outside" market held at 9½@9¾c. per lb. There was no buying interest in futures.

Phenol—Scattered lots of U.S.P. phenol sold on spot at 54@55c. per lb. The demand was slow all week and the undertone was barely steady. With the trade talking increased production, buyers were disposed to hold off. Leading makers quote around 27@28c. on contract.

Salicylic Acid—A quotation of 40c. per lb. was named in more than one direction, but this failed to bring out a general downward revision in prices. In fact the largest producer refused to shade 50c. per lb. The keen competition among certain producers of salicylates, which has unsettled the market in all directions, had also curtailed buying. The revised list of prices, announced by several factors within the past week, follows: Sodium salicylate, U.S.P., 47c.; acid salicylic, U.S.P., 40c.; acid acetylsalicylic, U.S.P., 95c.; salol, U.S.P., 85c. Methyl salicylate was unchanged at 62c. per lb.

Beta Naphthol—Producers continue to quote the market on the 23c. per lb. basis, but in outside channels price cutting is being resorted to.

Aniline Oil—The market was steady at the close at 16c. per lb., round-lot basis, prompt shipment.

Xylene—First hands were sellers on contract at 75c. per gal. for the pure, but had little to offer. Second hands continue to quote around $1 per gal., spot.

Financial Notes

The annual report of the Anton Jurgens' United Margarine Works of Holland shows net income in 1922 of $f,931,723, leaving a balance of $1,446,223 after payment of all interest and full dividends on preference shares.

The Beech-Nut Packing Co. for the first 3 months of 1923 reports net earnings of $595,787 after all charges, but before providing for Federal taxes. This compares with net earnings of $392,291 in the same period last year.

A readjustment of capital of the St. Louis Coke & Chemical Co. of St. Louis has been completed. The reorganized company will be called the St. Louis Coke & Iron Co.

The Vacuum Oil Co. has declared a semi-annual dividend of $1 a share on the new $25 par stock, payable June 20 to stock of record May 31. This is equal to 32 per cent on the old stock of $100 par. Last year 16 per cent was declared on $100 par stock.

An addition of $75,000,000 to its authorized capital stock, increasing it from $225,000,000 to $300,000,000, has been proposed by the Standard Oil Co. of New York.

Income account of Devoe & Raynolds Co., Inc., for the year ended Dec. 31, shows net profits of $704,995, after charges, depreciation, and taxes. Consolidated income account for the year shows net sales of $10,077,924; cost of sales, $6,147,393; operating profit, $3,930,531, and total income, $4,007,134.

The Kennecott Copper Corporation for the first quarter of 1923 reports total income of $4,963,453 and net income of $4,395,203 after allowing for interest obligations totaling $568,250. Net income for the first quarter of the year was equal to $1.56 a share on the outstanding capital stock, against 28 cents a share earned in the last quarter of 1922.

Vegetable Oils and Fats

Coconut Weak on Selling Pressure—Linseed Futures Unsettled—Cottonseed Steadies—China Wood Lower—Tallow 7½c.

INQUIRY for vegetable oils in the edible group showed moderate improvement, but this could not be said of the technical descriptions. Prices were unsettled and declines were registered in coconut, corn, china wood and palm oils. Cottonseed, both crude and refined, steadied on smaller offerings, reflecting a tight statistical position on old crop oil. The break in tallow prices was a feature in the week's developments. Linseed oil was dull and sentiment favored buyers. Soya bean oil was barely steady. Olive oil foots was unsettled on lack of demand.

Linseed—Spot oil sold at $1.14 per gal., carlots, cooperage included, indicating that crushers were not in a hurry to lower prices. On June deliveries, however, business was booked at $1.09 per gal., cooperage terms, while on July oil nominal prices ranged from $1.03@$1.05 per gal. The forward positions were unsettled throughout the week, and some consumers, who have lost confidence in the market, resold contracts at sharp concessions. Crushers admitted that July-August-September oil might have been obtained at less than $1 per gal. on a firm bid. Demand, taken as a whole, was quiet. Foreign oil was offered freely on spot and sales went through at prices ranging from $1@$1.06 per gal., duty paid. The cost of import was high towards the close and May shipment from abroad settled around $1.06@$1.08 per gal., duty paid, landed weights, New York. Importations of flaxseed from the Argantine have been heavy. Crushers have virtually caught up on contract deliveries, but have not yet had an opportunity to accumulate a surplus in either seed or oil. Foreign crushers believe that the future of the market hinges upon the state of trade in America. Continued heavy absorption of oil by consumers in this country would tend to steady the seed situation. The acreage planted to flaxseed in the United States will have some bearing on the market, and from latest reports a fair increase in the plantings may be expected. The Argentine seed movement continues large, while Indian shipments have been in excess of 500,000 bu. weekly for some time now. Linseed cake for export was dull and prices nominal at $34.50@$35.50 per ton, f.a.s. New York.

Cottonseed—Prices did not move much one way or the other, but a steadier undertone was in evidence, reflecting apprehension over the tight statistical position and the improvement in lard and other speculative markets. Shorts were the buyers of May oil in the option market on the Produce Exchange and business went through at higher than 11¼c. per lb., in prime summer yellow. The December option settled around 8⅞c. per lb., but interest in the distant months was of a desultory character. Refiners' brokers were credited with buying July and September oil, at least part of which represented covering. Cotton prices did better on unfavorable weather news from the south, which also exerted some influence on oil. The Chicago lard stocks on May 15 were estimated at 30,455,152 lb., against 34,212,572 lb. on the first of the month, the shrinkage causing considerable surprise in the oil trade. Crude oil held at 9⅞@10c. per lb., f.o.b mills, with offerings scanty. Bleachable oil was offered at 10¾c. per lb., f.o.b. Texas points. Lard compound held at 13@13¼c., f.o.b. New York. Oleo stearine was dull at 10c. nominal.

China Wood Oil—The market was weak, May delivery at New York selling at 25c. per lb., while June-July brought 23c. per lb. Demand was quiet and prices easy, even at the decline.

Coconut Oil—The sale of 700 tons of Manila oil at 8c. coast, bulk basis, was reported last week. Selling pressure was in evidence on the coast and on tank car offerings, nearby oil, prices ranged 8⅛@8¼c. In New York the feeling was not so bearish and the price on Ceylon type oil in sellers' tanks settled at 8⅝@8⅞c., according to position. Copra was offered at 5⅛@5⅝c., c.i.f. New York.

Corn Oil—Crude was lowered to 9⅛@9⅜c., sellers' tanks, f.o.b. point of production.

Olive Oil — Denatured closed unchanged at $1.10@$1.15 per gal., in barrels, spot. Prime green sulphur oil (foots) closed barely steady at 9⅛@9⅜c. per lb., spot New York, with demand quiet.

Palm Oil—The decline in tallow restricted buying in palm oils to a minimum and prices at the close were more or less nominal. Lagos was offered at 7⅞c., spot, one parcel of 200 tons being available at this figure.

Soya Bean Oil—Crude soya was offered at 10¼c., coast, and 10½c. New York, sellers' tanks, duty paid, nearby positions. Demand was dull. One car of spot oil was offered at 10⅞c., Atlantic port.

Fish Oils—No sales went through in crude menhaden oil. The nominal quotation on forward material held at 50c. per gal., tanks, f.o.b. factory. Newfoundland cod oil held at 70@72c. per gal., f.o.b. New York.

Tallow and Greases—The sales of several hundred drums of extra tallow went through at 7½c. per lb., f.o.b. plant, a decline of ½c. for the week. At the weekly London auction prices were unchanged. House grease was offered at 6⅞@7c. per lb., according to acidity.

London Tallow Auction

At the weekly tallow auction, held in London, May 16, 731 casks were offered and 644 casks sold. Prices realized were unchanged.

Miscellaneous materials

Casein—Arrivals from foreign sources were heavy, amounting to 4,870 bags. Offerings increased and the market presented an unsettled appearance. Prices named on the ordinary grades ranged from 20@25c. per lb., depending upon the quantity and seller.

Glycerine— While refiners did not alter prices for the c.p. grade, holding out for 17½c. asked, in drums, it was intimated that certain operators took on business at 17c., drums included. Trading was inactive. Chicago quoted 17c. as the market for c.p. Dynamite glycerine sold late in the week at 16c. per lb., carload lots, drums included, a decline of ½c. from the nominal price of a week ago. Demand for dynamite glycerine was quiet. Crude soap lye, basis 80 per cent, loose, held at 11¼c. asked, eastern territory, while in the Middle West 11c. represented the nominal asking price. On saponification, 88 per cent, loose, 12½c. was asked, with no transactions to report.

Turpentine—Inquiry from foreign as well as domestic buyers sent prices sharply higher and late in the week the nominal quotation stood at $1.22½ per gal., which compares with $1.08, the recent low. Southern markets developed strength and this stimulated buying interest. However, after the rise the demand met with a setback.

Shellac—Cables were about unchanged and importers continued to offer T. N. on spot at 64@66c. per lb. Bleached, bonedry, held at 76@78c. per lb. Superfine orange was available at 68@70c. per lb. Trading was inactive.

White Lead— Corroders considered changing prices, but at the last minute it was decided upon to maintain the list on the basis of 9⅜c. per lb. for the standard dry, in cask, round-lots. The pig lead market seemed to steady and this checked the easier undertone for the time being. Pig lead was unchanged at 7¼c., New York.

Zinc Oxide—New business was routine only, but deliveries against existing contracts absorbed the bulk of the production and leading producers reported a steady situation. Production of tires has not yet been restricted to the point where zinc oxide business is likely to suffer. American process, lead free, held at 8@8¼c. per lb. French process, red seal, closed unchanged at 9⅜c. per lb.

Argentine Linseed Exports

Shipments of linseed from the Argentine from Jan. 1, 1923, to May 12, 1923, by countries, were:

	Bushels
United Kingdom	2,120,000
Continent	8,920,000
United States	13,128,000
To order	4,868,000
Total	29,036,000

The visible supply at the Argentine ports on May 12 was estimated at 4,000,000 bushels. The shipments to-date exceed all previous shipments for a like period.

Imports at the Port of New York

AMMONIUM—10 csk carbonate, Liverpool, Order; 8 csk sulphocyanide, Liverpool, Order, 1183 csk nitrate, Hamburg Kuttroff, Pickhardt & Co

ASBESTOS—950 bg., Southampton, W D. Crumpton & Co

BARIUM HYDRATE—21 csk, Hamburg, E Suter & Co

BARIUM SUPEROXIDE—68 bbl. Hamburg, F. Boehm

BARIUM PEROXIDE—99 csk., Hamburg., W. A. Brown & Co., 62 dr., Havre, Mallinckrodt Chem. Wks., 124 dr., Havre, Gulf Merc. Corp

BARYTES 600 bg, Bremen, N. Y. Trust Co., 599 bg, Bremen, Order; 17 csk., Hamburg, Order.

BARIUM CHLORIDE 52 csk, Antwerp, Order.

CAMPHOR—100 cs., Kobe, Nat'l Park Bank; 200 cs., Kobe, Mitsui & Co.; 56 cs., Shanghai, Eastman Kodak Co.; 100 cs., Hamburg, A. Ochse Co.

CASEIN—667 bg, Buenos Aires, Equitable Trust Co.; 84 bg., Buenos Aires, Nat'l City Bank, 417 bg., Buenos Aires, Williamson Trading Co.; 2002 bg., Buenos Aires Kalbfleisch Corp.; 100 bg., London, A. Hurst & Co., 250 bg., Bordeaux, N. Y. Trust Co, 100 bg., Bordeaux, Nat'l City Bank, 833 bg., Buenos Aires, Equitable Trust Co.; 417 bg, Buenos Aires, Irving Bank-Col. Trust Co.

CREOSOTE—6015 tons, Antwerp, American Creosoting Co.; 60 dr., Leith, Order

CHEMICALS—46 csk., Hamburg Roessler & Hasslacher Chem. Co, 93 pkg., Bremen, Pfaltz & Bauer, 7 cs., Antwerp Ciba Co.; 157 pkg, Rotterdam, Order, 149 pkg., Antwerp, Order, 63 bbl Hamburg, Roessler & Hasslacher Chem. Co.; 242 pkg, Hamburg, Jungmann & Co.

CHALK—500 tons, London, Baring Bros. & Co.; 3,000 bg., Antwerp Bankers Trust Co.; 2,200 bg., Antwerp, Irving Bank-Col. Trust Co., 2,000 bg., Antwerp, Order; 1,828 tons (bulk), Dunkirk, Taintor Trading Co.; 500 tons (bulk), Dunkirk, J. Higman

COLORS—68 csk., Havre, Ciba Co; 58 csk. aniline Havre, Sandoz Chem. Works; 2 csk do., Havre, Order; 24 pkg, Hamburg, Kuttroff, Pickhardt & Co; 20 pkg., Hamburg, Grasselli Chem Co.; 19 cs dry, Bremen, M G. Lange & Co.; 5 keg aniline, Antwerp, Am. Ex Nat'l Bank; 16 pkg., aniline, Antwerp, Irving Bank-Col Trust Co.; 4 csk., Antwerp, Order; 8 csk. dry, Southampton, Order; 14 pkg. aniline, Havre, Sandoz Chem. Wks., 1 pkg., aniline, Rotterdam, Am. Aniline Products, Inc.; 11 csk. and 1 cs., Rotterdam, B. Mernard; 8 pkg., Rotterdam, F. Donders; 3 csk. Rotterdam, Order; 162 pkg. earth, Leghorn, Reichard-Coulston, Inc.; 65 csk. ochre, Marseilles, Gledhill & Co.; 6 dr. aniline, Liverpool, Am. Exchange Nat'l Bank; 12 csk. earth, Hamburg, E. M. & F. Waldo; 26 csk. earth, Hamburg, J. H. Furman Co.; 50 csk. do., Hamburg, C. J. Osborn & Co.; 37 csk. ochre, Bordeaux, Butcher & Co.; 10 csk. aniline, Hamburg, Guaranty Trust Co.; 13 csk., Hamburg, H. A. Metz & Co.; 7 cs. aniline, Hamburg, Carbic Color & Chem. Co.

COPPER SULPHATE—156 csk., Hamburg, A. Klipstein & Co.

COPRA—21,444 bg., Cebu, Order.

CREAM TARTAR—40 bbl., Genoa, Order, 40 csk., Bordeaux, National City Bank.

DIVI-DIVI—769 bg., Monte Cristi, M. J. Petit.

EPSOM SALT — 500 bbl., Hamburg, Hansa Co.

FERTILIZER—2,500 bg. bonemeal, Karachi, Ralli Bros

FLUORSPAR—975 bg., Hamburg, H. Sundheimer, 400 bg., Hamburg, A. Klipstein & Co.

FULLERS EARTH—950 bg., London, L. A. Salomon & Bros.

FUSEL OIL 12 csk., Antwerp, Guaranty Trust Co., 8 csk., Hamburg, A. Klipstein & Co., 6 dr., Hamburg, Order, 68 bbl. and 13 dr, Hamburg, Order, 9 csk., Genet, Maas & Waldstein, 5 dr., Dunkirk, Maas & Waldstein, 10 dr., Dunkirk, Guaranty Trust Co.; 3 dr., Dunkirk, Order.

GAMBIER—198 cs, Singapore, Order.

GLAUBERS SALT—278 bg., Hamburg, Roessler & Hasslacher Chem Co.

GLYCERINE 6 dr., Liverpool, Br. Am. Tobacco Co., 20 csk., Marseilles, Order; 41 dr., Antwerp, N. Y. Trust Co, 10 csk., Nazaire, Marx & Rawolle.

GUMS—100 cs. damar, Padang, Order, 270 pkg. copal, Macassar, Brown Bros & Co., 1,200 pkg. do., Macassar, Kidder, Peabody & Co., 3,855 pkg. do., Macassar, Order, 250 bg arabic, Port Sudan, Thurston & Braidich, 250 bg. arabic, Port Sudan, T M Duche & Sons; 500 bg. arabic, Port Sudan, Caraconda Bros., 250 bg. arabic, Port Sudan, W. Tappenbeck; 200 pkg. damar, Batavia, W. H. Muller & Co.; 155 pkg copal, Singapore, Irving Bank-Col. Trust Co, 350 bg. damar, Singapore, Kidder, Peabody & Co; 255 bg do, Singapore, Baring Bros. & Co., 140 bg damar, Singapore, Order, 901 pkg. copal, Macassar, Nat'l City Bank, 553 pkg. copal, Macassar, Order, 810 pkg. copal, Brown Bros & Co, 72 pkg. copal, Macassar, Irving Bank-Col. Trust Co, 5,191 pkg. copal, Macassar, Order, 3,103 pkg. copal, Antwerp, Order, 30 bg. copal, Antwerp, Order, 125 bg. copal, London, Chem. Nat'l Bank.

IRON OXIDE—100 bbl Malaga, Scott, Libby & Co., 95 bbl., Malaga, J. L. Smith & Co., 91 bbl., Malaga, Reichard-Coulston, Inc, 81 bbl., Malaga, Order, 86 bbl., Malaga, S C. Goldberg, 298 bbl. Malaga, C K. Williams & Co., 111 bbl., Malaga, Reichard-Coulston, Inc.; 125 bbl., Malaga, E M. & F. Waldo; 303 bbl., Malaga, C. J. Osborne & Co.; 114 bbl., Malaga, Hummel & Robinson Co.; 17 csk., Liverpool, E. M. & F. Waldo, 39 csk., Hull, J. L Smith & Co, 40 csk, Liverpool, J. A. McNulty; 15 csk, Liverpool, Order; 25 csk, Manchester, Order; 25 csk., Leith, Reichard-Coulston, Inc.

IRON SULPHATE—88 csk., Antwerp, E. M Sergeant & Co.

LITHOPONE — 200 csk., Antwerp, A. Klipstein & Co.; 999 csk., Antwerp, Benj. Moore & Co.; 80 csk., Antwerp, E. M. & F. Waldo.

MAGNESITE—250 bg. calcined, Rotterdam, H. J. Baker & Bro.; 105 bg. do., Rotterdam, Spelden.

MAGNESIUM—40 cs. carbonate, Hull, Van Oppen & Co.; 61 dr. chloride, Hamburg, Innis, Spelden & Co.; 345 bbl. chloride Hamburg, Hansa Co.; 182 dr. chloride, Hamburg, Innis, Spelden & Co.

MANGROVE BARK—1,500 bg. extract, Singapore, Order

MYROBALANS—1,824 pkts. Calcutta, Nat'l City Bank, 10,263 pkts., Calcutta Order.

NAPHTHALENE—328 bg., Hamburg, Irving Nat'l Bank; 218 bg., Hamburg, Irving Bank-Col. Trust Co.; 894 bg., Hamburg, Calco Chem. Co.; 500 bg., London; Order

OILS — Castor — 55 bbl, Hull, Brown Bros & Co.; 200 bbl., Hull, Order **Cod**—160 bbl., Hull, Order; 100 bbl., Hamburg, Order. **China Wood**—152 bbl, Hankow, Int'l Banking Corp, 109 csk., Hamburg, Order **Linseed**—146 bbl., London, Order; 146 bbl., London, Irving Bank-Col. Trust Co; 120 bbl, Rotterdam, I. R Boody & Co.; 1157 bbl., Rotterdam, L. & E Frankel; 291 bbl., Rotterdam, J. C Francesconi Co.; 146 bbl, Rotterdam W. Benkert Co.; 144 bbl, Rotterdam, Bur-Mac Chem. Corp; 371 bbl Rotterdam, Order; 1019 bbl, Hull, Nat'l City Bank; 800 tons in bulk, Hull, Am. Linseed Co.; 450 bbl., Hull, Order; 725 bbl., Copenhagen, Order; 770 tons, Leith Midland Linseed Products Co. **Olive Oil Foots**—(sulphur oil)—500 bbl., Naples, Brewer & Co.; 200 bbl., Messina, Bank of the Manhattan Co.; 200 bbl., Messina, First Nat'l Bank of Phila.; 100 bbl., Palermo, Banca Comm. Ital., 100 bbl., Malaga, Elbert & Co.; 400 bbl., Syracuse, Order; 200 bbl., Catania, Mech. & Metals Nat'l Bank; 200 bbl., Catania, Order; 200 bbl., Milazzo, Order. **Palm**—499 csk., Seccondee, Order; 48 pkg., Liverpool, D. Bacon; 474 csk., Liverpool, African & Eastern Trading Corp, 69 csk, Liverpool, Order. **Rapeseed**—1144 bbl., Liverpool, Vacuum Oil Co.; 200 bbl., Hull, Nat'l City Bank; 335 bbl., Hull, Order; 75 bbl., Leith, Order. **Sesame**—144 csk., Rotterdam, Order.

OIL SEEDS—Castor—1844 bg., Santos, F. Matarazzo & Co.; 373 bg., Santos, Bank of N. Y & Trust Co.; 4400 bg., Santos, F. Matarazzo & Co. **Linseed**—87,350 bg., Rosario, Spencer Kellogg & Sons; 17,676 bg., Buenos Aires, Spencer Kellogg & Sons, 60,957 bg., Diamante, Order; 8,502 bg., Bajada Grande, Order; 26,407 bg., Buenos Aires, Order; 8,827 bg., Buenos Aires, L. Dreyfus & Co.; 6,088 bg., Buenos Aires, Order; 17,858 bg., Buenos Aires, L. Dreyfus & Co., 24,090 bg., Buenos Aires, Am. Linseed Co., 51,014 bg., Buenos Aires, Order.

POTASSIUM SALTS — 100 bbl., bicarbonate, Hamburg, Brown Bros & Co.; 449 csk., nitrate, Hamburg, Kuttroff, Pickhardt & Co., 34 dr, caustic, Bremen, Brown Bros. & Co., 14 csk., carbonate, Bremen, P. H. Petry & Co.; 2,000 bg., sulphate, Bremen, A. Vogel; 30 dr., permanganate, Hamburg, E. E Reifenberg, 581 dr., caustic, Hamburg, A. Klipstein & Co., 37 dr., caustic, Hamburg, Order; 424 dr., permanganate, Hamburg, Order; 2,625 bg., muriate, Antwerp, Societe Comm. des Potasses D'Alsace, A quantity of Kainit, Antwerp, Societe Comm. des Potasses D'Alsace, 62 csk., carbonate, Hamburg, Innis, Spelden & Co., 400 pkg., salts, Hamburg, Roessler & Hasslacher Chem. Co.; 21 csk, carbohydrate, Hamburg, Globe Shipping Co.; 200 bbl., bicarbonate, Hamburg, Mallinckrodt Chem Works, 100 cs alum, Hamburg, Order.

PITCH—767 bbl., Hull, Order.

QUEBRACHO—2,017 bg., Buenos Aires, Guaranty Trust Co; 6,128 bg, Buenos Aires, Nat'l Bank of Commerce, 6,955 bg., Buenos Aires, Order, 937 bg., Buenos Aires, Nat'l Bank of Comm.; 21,025 pcs, Santa Fe, Tannin Corp.; 6,000 bg., extract, Buenos Aires, Tannin Corp.; 10,075 bg, extract, Buenos Aires, Tannin Corp, 4 100 bg., Buenos Aires, Fourth Atl. Nat'l Bank of Boston.

QUICKSILVER—100 flasks, London, A. Pickering & Co

SHELLAC — 40 cs, London, Mech. & Metals Nat'l Bk; 100 bg., London, Order, 300 bg., Calcutta, Brown Bros. & Co., 520 bg., Calcutta, Bank of Br. West Africa, 350 pkg, Calcutta, Irving Bank-Col. Trust Co.; 200 bg., Calcutta, Br. Bank of South America, 150 bg., Calcutta, Chase Nat'l Bank; 600 bg., refuse lac, Calcutta, Bank of the Manhattan Co.; 50 cs., Calcutta, First Fed. For. B'k'g Corp.; 10 bg., Calcutta. Phil. Nat'l Bank; 3,429 bg., 200 chests, 338 pkg, button, 200 pkg., garnet, 75 cs., seed, and 40 bg., refuse, Calcutta Order; 13 chests button, Hamburg, A. Holmrath.

SODIUM SALTS — 1845 bg. nitrate, Mejillones, Wessel, Duval & Co.; 9,857 bg. nitrate, Iquique, Wessel, Duval & Co.; 15 csk. carbonate, Liverpool, J. Turner & Co; 119 csk. sulphide, Hamburg, A. Klipstein & Co.; 109 dr. sulphide, Hamburg, Order; 10 csk. hyposulphite, Hamburg, Kuttroff, Pickhardt & Co.; 268 dr. sulphohydrate, Hamburg, C S. Grant & Co.

SUMAC—700 bg., Palermo, Order.

STRONTIUM NITRATE—38 csk., Hamburg, Meteor Products Co.

TALC—700 bg., Genoa, C. Mathieu; 200 bg., Genoa, Kountze Bros.; 450 bg., Genoa, Parfume de Luxe Co.; 200 bg., Genoa, Order; 1,000 bg., Genoa, Ital. Discount & Trust Co.

TANNIN—12 csk., Antwerp, Geigy Co

TARTAR—58 bg, Malaga, Tartar Chem. Works

TALLOW—414 csk., Buenos Aires, Nat'l City Bank; 162 csk., Buenos Aires, Swift & Co.; 286 tcs., Buenos Aires, Nat'l City Bank.

WATTLE BARK—1,824 bg., Durban, E J. Haley, Inc.; 11,659 bg, Durban, Tannin Corp.; 2,592 bg., Durban, Order.

WAXES — 113 bg. bees, San Antonio, Equitable Trust Co.; 86 bg. do, Valparaiso, W. R. Grace & Co.; 175 bg. do, Valparaiso, Banco Anglo Sud. Am; 51 bg. bees, San Antonio Guaranty Trust Co.; 314 bg. bees, Lisbon Order; 36 bg. bees, Valparaiso, Guaranty Trust Co.; 332 bg. carnauba, Santos, F. Matarazzo & Co.; 26 bg. bees, Rio de Janeiro, Order.

ZINC CHLORIDE — 37 dr., Hamburg, Innis, Spelden & Co.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 38 -	
Acetone, drums	lb	.25 -	25½
Acid, acetic, 28%, bbl	100 lb	3 38 -	3 50
Acetic, 56%, bbl	100 lb	6 75 -	7 00
Glacial, 99½%, bbl	100 lb	12 00 -	12 50
Boric, bbl	lb	10½ -	
Citric, kegs	lb	49 -	52
Formic, 85%	lb	14 -	16
Gallic, tech	lb	45 -	50
Hydrofluoric, 52%, carboys	lb	12 -	12½
Lactic, 44%, tech, light, bbl	lb	.11½-	12
22% tech, light, bbl	lb	05½-	06
Muriatic, 18° tanks	100 lb	90 -	1 00
Muriatic, 20°, tanks	100 lb	1 00 -	1 10
Nitric, 36°, carboys	lb	04½-	.05
Nitric, 42°, carboys	lb	06 -	06½
Oleum, 20%, tanks	ton	18 50 -	19 00
Oxalic, crystals, bbl	lb	.13½-	.13¾
Phosphoric, 50% carboys	lb	07½-	.08½
Pyrogallic, resublimed	lb	1.50 -	1 60
Sulphuric, 60°, tanks	ton	9 50 -	11 00
Sulphuric, 60°, drums	ton	13.00 -	14 00
Sulphuric, 66°, tanks	ton	16.00 -	16 50
Sulphuric, 66° drums	ton	20 00 -	21 00
Tannic, U S P, bbl	lb	65 -	70
Tannic, tech, bbl	lb	45 -	.50
Tartaric, imp crys, bbl	lb	.36½-	
Tartaric, imp, powd, bbl	lb	.36½-	
Tartaric, domestic, bbl	lb	37½-	
Tungstic, per lb	lb	1 10 -	1 20
Alcohol, butyl, drums, f o b works	lb	.26 -	.28
Alcohol ethyl (Cologne spirit), bbl	gal	4 75 -	4.95
Ethyl, 190 p'f U S P, bbl	gal	4 70 -	
Alcohol, methyl (see Methanol)			
Alcohol, denatured, 190 proof			
No 1, special bbl	gal	41 -	
No. 1, 190 proof, special, dr	gal	35 -	
No 1, 188 proof, bbl	gal	42 -	
No 1, 188 proof, dr	gal	36 -	
No 5, 188 proof, bbl	gal	40 -	
No. 5, 188 proof, dr	gal	.34 -	
Alum, ammonia, lump, bbl	lb	03½-	03¾
Potash, lump, bbl	lb	02¾-	03¼
Chrome, lump, potash, bbl	lb	05¼-	05½
Aluminum sulphate, com, bags	100 lb	1 50 -	1 65
Iron free bags	lb	.02½-	02¾
Aqua ammonia, 26°, drums	lb	06½-	07½
Ammonia, anhydrous, cyl	lb	.30 -	30½
Ammonium carbonate, powd casks, imported	lb	.09½-	.10
Ammonium carbonate, powd, domestic, bbl	lb	.13 -	.14
Ammonium nitrate, tech, casks	lb	10 -	.11
Amyl acetate tech, drums	gal	3 50 -	3 75
Arsenic, white, powd, bbl	lb	.14½-	15
Arsenic, red, powd, kegs	lb	14½-	14½
Barium carbonate, bbl	ton	78 00 -	80 00
Barium chloride, bbl	ton	85.00 -	90 00
Barium dioxide, drums	lb	.18 -	18½
Barium nitrate, casks		.08 -	08½
Barium sulphate, bbl	lb	.04 -	04½
Blanc fixe, dry, bbl	lb	.04 -	.04½
Bleaching powder, f o b wks, drums	100 lb	1 90 -	
Spot N Y drums	100 lb	2 40 -	
Borax, bbl	lb	05½-	05½
Bromine, cases	lb	28 -	30
Calcium acetate, bags	100 lb	4 00	4 05
Calcium arsenate, dr	lb	17 —	18
Calcium carbide, drums	lb	05½	05½
Calcium chloride, fused, drums	ton	22 00 -	23 00
Gran drums	ton	28 00 -	30 00
Calcium phosphate, mono, bbl	lb	06½-	07
Camphor, cases	lb	86 -	.88
Carbon bisulphide, drums	lb	07 -	07½
Carbon tetrachloride, drums	lb	09½-	10
Chalk, precip.—domestic, light, bbl	lb	04½-	.04½
Domestic, heavy, bbl	lb	03½-	03¾
Imported, light, bbl	lb	.04½-	05
Chlorine, liquid, cylinders	lb	06 -	06½
Chloroform, tech, drums	lb	35 -	38
Cobalt oxide, bbl	lb	2 10 -	2 25
Copperas, bulk, f o b wks	ton	19 00 -	20 00
Copper carbonate, bbl	lb	19 -	20
Copper cyanide, drums	lb	.47 -	50
Coppersulphate, dom., bbl	100 lb	6 00 -	6 25
Cream of tartar, bbl	lb	.25½-	26½
Epsom salt, dom., tech, bbl	100 lb	1.90 -	2 15
Epsom salt, imp, tech, bags	100 lb	1.00 -	1 15
Epsom salt, U.S.P., dom., bbl	100 lb	2.50 -	2 60
Ether, U.S.P., drums	lb	.13 -	15
Ethyl acetate, com., 85%, drums	gal	.80 -	.85
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal	.95 -	1.00
Formaldehyde, 40%, bbl	lb	$0 14½-	$0 15¼
Fullers earth—imp, powd, net	ton	30 00 -	32 00
Fusel oil, ref, drums	gal	3 55 -	4 05
Fusel oil, crude, drums	gal	2 50 -	2 60
Glaubers salt, wks, bags	100 lb	1.20 -	1 40
Glaubers salt, imp, bags	100 lb	90 -	95
Glycerine, c p, drums extra	lb	.17½-	
Glycerine, dynamite, drums	lb	16 -	
Glycerine, crude 80%, loose	lb	11	11½
Iodine, resublimed	lb	4 55 -	4 65
Iron oxide, red, casks	lb.	12 -	.18
Lead			
White, basic carbonate, dry, casks	lb.	.09¾-	.10
White, basic sulphate, casks	lb	.09½-	
White, in oil, kegs	lb	12½-	14
Red, dry, casks	lb	11¾-	12
Red, in oil, kegs	lb	13½-	.15
Lead acetate, white crys, bbl.	lb	14 -	14½
Brown, broken, casks	lb	13 -	13½
Lead arsenate, powd, bbl	lb	23 -	24
Lime-Hydrated, bbl	per ton	16 80 -	17 00
Lime, Lump, bbl	280 lb	3 63 -	3 65
Litharge, comm, casks	lb	10¾-	11
Lithophone, bags	lb	07 -	07½
in bbl	lb	07	07¾
Magnesium carb, tech, bags	lb	08 -	08½
Methanol, 95%, bbl	gal	1 18 -	1 20
Methanol, 97%, bbl	gal	1 20 -	1 22
Nickel salt, double, bbl	lb	10½-	
Nickel salts, single, bbl	lb	11½-	
Phosgene		60 -	75
Phosphorus, red, cases	lb	35 -	.40
Phosphorus, yellow, cases	lb	30 -	35
Potassium bichromate, casks	lb	11¼-	11½
Potassium bromide, gran, bbl	lb.	19 -	20
Potassium carbonate, 80-85%, calcined, casks	lb	.06¾-	07¼
Potassium chlorate, powd	lb	07½-	08
Potassium cyanide, drums	lb	45 -	50
Potassium, first sorts, cask	lb.	08¼	09
Potassium hydroxide (caustic potash) drums	lb	07¾-	09
Potassium iodide, cases	lb	3 65 -	3 75
Potassium nitrate, bbl	lb	.06¾-	07¼
Potassium permanganate, drums	lb.	19 -	20
Potassium prussiate, red, casks	lb	70 -	72
Potassium prussiate, yellow, casks	lb	36½-	37
Salammoniac, white, gran, casks, imported	lb.	.07 -	07¼
Salammoniac, white, gran, bbl, domestic	lb	.07¾-	.08
Gray, gran, casks	lb.	.08 -	.09
Salsoda, bbl	100 lb	1 20	1 40
Salt cake (bulk)	ton	26 00 -	28 00
Soda ash, light, 58% flat, bags, contract	100 lb	1 60 -	1 67
Soda ash, light, basis, 48%, bags, contract, f o b wks	100 lb	1 20 -	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb.	1.75 -	1.80
Soda ash, dense, bags, contract, basis 48%	100 lb	1.17½-	1 20
Soda ash, dense, in bags, resale	100 lb	1.85 -	1.90
Soda, caustic, 76%, solid, drums, f a s	100 lb.	3.30 -	3 40
Soda, caustic, basis 60%, wks, contract	100 lb.	2.50 -	2.60
Soda, caustic, ground and flake, contracts	100 lb.	3 80 -	3.90
Soda, caustic, ground and flake, resale	100 lb.	3.72½-	..
Sodium acetate, works, bags	lb.	.05½-	.06½
Sodium bicarbonate, bbl	100 lb.	2.00 -	2 50
Sodium bichromate, casks	lb.	.08½-	08½
Sodium bisulphate (niter cake)	ton	6.00 -	7.00
Sodium bisulphite, powd., U.S.P., bbl	lb	.04½-	.04½
Sodium chlorate, kegs	lb.	.06½-	.07
Sodium chloride	long ton	12.00 -	13.00
Sodium cyanide, cases	lb.	.20 -	.23
Sodium fluoride, bbl	lb.	$0.09 -	$0 10½
Sodium hyposulphite, bbl	lb.	.02½-	.03
Sodium nitrite, casks	lb.	.08 -	.08½
Sodium peroxide, powd, cases	lb.	.28 -	.30
Sodium phosphate, dibasic, bbl	lb.	.03½-	.04
Sodium prussiate, yel drums	lb.	.16½-	.17½
Sodium salicylic, drums	lb	.47 -	57
Sodium silicate (40°, drums)	100 lb.	.80 -	1.25
Sodium silicate (60°, drums)	100 lb.	2.00 -	2.25
Sodium sulphide, fused, 60-62%, drums	lb.	.04½-	.04½
Sodium sulphite, crys, bbl	lb.	.03½-	.03½
Strontium nitrate, powd, bbl.	lb.	.12½-	.13
Sulphur chloride, yel drums.	lb.	.04½-	.05
Sulphur, crude	ton	18.00 -	20.00
At mine, bulk	ton	16.00 -	18.00
Sulphur, flour, bag	100 lb	2.25 -	2.35
Sulphur, roll, bag	100 lb.	2 00 -	2.10
Sulphur dioxide, liquid, cyl	lb.	.08 -	.08½
Talc—imported, bags	ton	30 00 -	40.00
Talc—domestic powd, bags.	ton	18 00 -	25.00
Tin bichloride, bbl	lb.	.12½-	.13¾
Tin oxide, bbl	lb.	.50 -	
Tin crystals, bbl	lb.	.35½-	.36
Zinc carbonate, bags	lb.	.14 -	.14½
Zinc chloride, gran, bbl.	lb.	.06 -	.07
Zinc cyanide, drums	lb.	.37 -	.38
Zinc oxide, lead free, bbl.	lb.	.08 -	.08½
5% lead sulphate, bags	lb.	.07½-	......
10 to 35% lead sulphate, bags	lb.	.07 -	.....
French, red seal, bags	lb.	.09¾-	.....
French, green seal, bags	lb.	.10¾-	......
French, white seal, bbl	lb.	.12 -	.....
Zinc sulphate, bbl.	100 lb.	2.50 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb.	$0.65 -	$0.80
Alpha-naphthol, ref, bbl	lb.	.75 -	.90
Alpha-naphthylamine, bbl.	lb.	.35 -	.37
Aniline oil, drums	lb.	.16 -	.16½
Aniline salts, bbl	lb	.24 -	.25
Anthracene, 80%, drums	lb.	.75 -	1.00
Anthracene, 80%, imp, drums, duty paid	lb.	.70 -	.75
Anthraquinone, 25%, paste, drums	lb.	.70 -	.75
Benzaldehyde U S P, carboys	lb.	1.40 -	1.45
tech, drums	lb	75	80
Benzene, pure, water-white, tanks and drums	gal.	.30 -	.32
Benzene, 90%, tanks & drums	gal.	.27 -	.30
Benzene, 90%, drums, resale	gal.	.30 -	.33
Benzidine base, bbl	lb.	.85 -	.90
Benzidine sulphate, bbl	lb.	.70 -	.75
Benzoic acid, U S P, kegs	lb.	.72 -	75
Benzoate of soda, U S P, bbl.	lb.	.57 -	65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 -	
Benzyl chloride, tech, drums	lb.	.30 -	.35
Beta-naphthol, subl, bbl	lb	.55 -	.60
Beta-naphthol, tech, bbl	lb.	.22 -	.23
Beta-naphthylamine, tech	lb.	.80 -	.90
Cresol, U S P, drums	lb.	.25 -	.29
Ortho-cresol, drums	lb.	.28 -	.30
Cresylic acid, 97%, resale, drums	gal.	1.25 -	....
95-97%, drums, resale	gal.	1.15 -	1.25
Dichlorbenzene, drums	lb.	.07 -	.09
Diethylaniline, drums	lb.	.50 -	.60
Dimethylaniline, drums	lb.	.42 -	.43
Dinitrobenzene, bbl,	lb.	.19 -	.20
Dinitroclorbenzene bbl.	lb.	.22 -	.23
Dinitronaphthalen, bbl	lb.	.30 -	.32
Dinitrophenol, bbl	lb.	.35 -	.40
Dinitrotoluene, bbl	lb.	.20 -	.22
Dip oil, 25%, drums	gal.	.25 -	.30
Diphenylamine, bbl	lb.	.50 -	.52
H-acid, bbl	lb.	.80 -	.85
Meta-phenylenediamine, bbl.	lb.	1.00 -	1.05
Michlers ketone, bbl	lb.	3.00 -	3.50
Monochlorbenzene, drums	lb.	.08 -	.10
Monoethylaniline, drums	lb.	.95 -	1.10
Naphthalene, flake, bbl	lb.	.09 -	.09½
Naphthalene, balls, bbl.	lb.	.09½-	.10½
Naphthionate of soda, bbl	lb.	.58 -	.65
Naphthionic acid, crude, bbl.	lb.	.55 -	.60
Nitrobenzene, drums	lb.	.10 -	.12
Nitro-naphthalene, bbl.	lb.	.30 -	.35
Nitro-toluene, drums.	lb.	.15 -	.17
N-W acid, bbl	lb.	1.25 -	1.30
Ortho-amidophenol, kegs	lb.	2.30 -	2.35
Ortho-dichlorbenzene, drums	lb.	.17 -	.20
Ortho-nitrophenol, bbl	lb.	.90 -	.92
Ortho-nitrotoluene, drums	lb.	.10 -	.12
Ortho-toluidine, bbl	lb.	.14 -	.15
Para-amidophenol, base, kegs	lb.	1.20 -	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 -	1.35
Para-dichlorbenzene, bbl	lb.	.17 -	.20
Paranitraniline, bbl.	lb.	.74 -	.75
Para-nitrotoluene, bbl	lb.	.60 -	.65
Para-phenylenediamine, bbl.	lb.	1.45 -	1.50
Para-toluidine, bbl	lb.	.95 -	.98
Phthalic anhydride, bbl	lb.	.35 -	.38
Phenol, U.S.P., drums	lb.	.54 -	.55
Picric acid, bbl.	lb.	.20 -	.22
Pyridine, dom., drums	gal.	nominal	

Pyridine, imp., drums	gal.	$2.50 - $2.75
Resorcinol, tech., kegs	lb.	1.40 - 1.50
Resorcinol, pure, kegs	lb.	2.00 - 2.25
R-salt, bbl.	lb.	.55 - .60
Salicylic acid, tech., bbl.	lb.	.47 - 48
Salicylic acid, U.S.P., bbl.	lb	40 - 50
Solvent naphtha, water-white, drums	gal.	37 - 40
Crude, drums	gal.	24 -
Sulphanilic acid, crude, bbl	lb	18 - 20
Thiocarbanilide, kegs	lb.	35 - 38
Toluidine, kegs	lb.	1.20 - 1 30
Toluidine, mixed, kegs	lb.	.30 - 35
Toluene, tank cars	gal.	.30 - 35
Toluene, drums	gal.	.35 - 40
Xylidines drums	lb.	47 - 49
Xylene, pure, drums	gal.	75 - 1 00
Xylene, com., drums	gal.	.37 -
Xylene, com., tanks	gal.	.32 -

Naval Stores

Rosin B-D, bbl.	280 lb.	$6 10 -
Rosin E-I, bbl.	280 lb.	6 10 -
Rosin K-N, bbl	280 lb	6 15 -
Rosin W G-W W., bbl	280 lb	6 50 - 7 50
Wood rosin, bbl	280 lb	6 00 - 6 10
Turpentine, spirits of, bbl.	gal.	1 22½ -
Wood, steam dist, bbl.	gal	1 00 -
Wood, dest dist, bbl.	gal.	75 -
Pine tar pitch, bbl	200 lb	- 6 00
Tar, kiln burned, bbl.	500 lb.	- 13 00
Retort tar, bbl.	500 lb.	- 12 00
Rosin oil, first run, bbl	gal	45 -
Rosin oil, second run, bbl.	gal	48 -
Rosin oil, third run, bbl	gal	.52 -
Pine oil, steam dist	gal.	75 -
Pine oil, pure, dest dist.	gal	70 -
Pine tar oil, ref.	gal.	48 -
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla.	gal.	32 - 32½
Pine tar oil, double ref, bbl.	gal.	- 75
Pine tar, ref, thin, bbl	gal.	- 25
Pinewood creosote, ref, bbl	gal.	- 52

Animal Oils and Fats

Degras, bbl	lb	$0 03¾ - $0 04¼
Grease, yellow, bbl	lb	07 - 07¼
Lard oil, Extra No 1, bbl	gal	90 - 92
Neatsfoot oil 20 deg bbl.	gal	1 30 -
No 1, bbl.	gal	92 - 94
Oleo Stearine		10 -
Red oil, distilled, d p bbl	lb	11 - 11½
Saponified, bbl	lb	11 - 11¼
Tallow, extra, loose	lb	07½ -
Tallow oil, acidless, bbl	gal.	.94 - .96

Vegetable Oils

Castor oil, No 3, bbl	lb	$0 14 -
Castor oil, No 1, bbl.	lb	14½ -
Chinawood oil, bbl	lb.	25 - 27
Coconut oil, Ceylon, bbl	lb	09¾
Ceylon, tanks, N Y	lb	08¾ - 08¾
Coconut oil, Cochin, bbl.	lb.	10 - 10¼
Corn oil, crude, bbl	lb	.12½
Crude, tanks, (f o b mill)	lb.	.09½ - 09¾
Cottonseed oil, crude (f.o.b. mill), tanks	lb	09¾
Summer yellow, bbl.	lb	12 -
Winter yellow, bbl.	lb.	13 - .13½
Linseed oil, raw, car lots, bbl.	gal.	1 14 -
Raw, tank cars (dom)	gal.	1 09 -
Boiled, cars, bbl. (dom).	gal.	1 16 -
Olive oil, denatured, bbl.	gal.	1 10 -
Sulphur, (foots) bbl	lb.	.09½ - 09¾
Palm, Lagos, casks	lb.	07½ - .07¾
Niger, casks	lb	07½ - .07¾
Palm kernel, bbl	lb	.08¾ - .09
Peanut oil, crude, tanks (mill)	lb	13½ -
Peanut oil, refined, bbl.	lb.	17 -
Perilla, bbl	lb	16½ - 16¾
Rapeseed oil, refined, bbl.	gal.	83 - 84
Rapeseed oil, blown, bbl	gal	88 - 89
Sesame, bbl	lb	11½ - 12½
Soya bean (Manchurian), bbl.	lb.	.12¾ - 13
Tank, f o.b. Pacific coast	lb	10½ - 10¾
Tank, (f o b. N Y.)	lb	10½ - 10¾

Fish Oils

Cod, Newfoundland, bbl	gal	$0 70 - $0 72
Menhaden, light pressed, bbl	gal	76 -
White bleached, bbl.	gal.	78 -
Blown, bbl.	gal	82 -
Crude, tanks (f o b factory)	gal.	50 -
Whale No. 1 crude, tanks, coast	lb	07¾ - 08
Winter, natural, bbl	gal	76 - 78
Winter, bleached, bbl	gal	79 - 80

Oil Cake and Meal

Coconut cake, bags	ton	$30 00 - $31 00
Copra, sun dried, bags (c i f)	lb	05¼ - 05½
Sun dried Pacific coast	lb	05¼ - 05½
Cottonseed meal, f o b mills	ton	38 00 -
Linseed cake, bags	ton	34 50 -
Linseed meal, bags	ton	36 50 -

Dye & Tanning Materials

Albumen, blood, bbl	lb.	$0 45 - $0 50
Albumen, egg, tech, kegs.	lb.	.80 - 85
Cochineal, bags	lb	35 - 36
Cutch, Borneo, bales	lb.	04½ - .05
Cutch, Rangoon, bales	lb.	13 - 13½
Dextrine, corn, bags	100 lb.	3 64 - 3 69
Dextrine gum, bags	100 lb.	3 99 - 4 09
Divi-divi, bags	ton	38 00 - 39 00
Fustic, sticks	ton	30 00 - 35.00
Fustic, chips, bags	lb.	.04 - .05
Logwood, sticks	ton	28.00 - 30 00
Logwood, chips, bags	lb	02½ - .03
Sumac, leaves, Sicily, bags	ton	70 00 - 72.00
Sumac, ground, bags	ton	$65 00 - $67 00
Sumac, domestic, bags	ton	40 00 - 42.00
Starch, corn, bags	100 lb	2.97 - 3 07
Tapioca flour, bags	lb	.05½ - 06¼

Extracts

Archil, conc, bbl	lb.	$0.17 - $0 18
Chestnut, 25% tannin, tanks.	lb	02 - 03
Divi-divi, 25% tannin, bbl	lb	04 - 05
Fustic, crystals, bbl	lb	20 - 22
Fustic, liquid, 42°, bbl	lb	08 - 09
Gambier, liq, 25% tannin, bbl.	lb	08 - 09
Hematine crys, bbl	lb	14 - 18
Hemlock, 25% tannin, bbl	lb	04 - 05
Hypernic, solid, drums	lb	24 - 26
Hypernic, liquid, 51°, bbl	lb	.14 - 17
Logwood, crys, bbl	lb.	19 - 20
Logwood, liq, 51°, bbl	lb.	.09 - 10
Quebracho, solid, 65% tannin, bbl	lb.	04½ - 05
Sumac, dom., 51°, bbl.	lb.	06½ - 07

Dry Colors

Blacks Carbongas, bags, f o b works	lb	$0 20 - $0 24
Lampblack, bbl	lb	12 - 40
Mineral, bulk	ton	35 00 - 45 00
Blues Bronze, bbl	lb	55 - 60
Prussian, bbl	lb	55 - 60
Ultramarine, bbl	lb	08 - 35
Browns, Sienna, Ital, bbl	lb	06 - 14
Sienna Domestic, bbl	lb	03½ - 04
Umber, Turkey, bbl	lb	04 - 04½
Greens Chrome, C P Light, bbl	lb	32 - 34
Chrome commercial, bbl	lb	12 - 12½
Paris, bulk	lb	30 - 35
Reds, Carmine No 40, tins	lb	4 50 - 4 70
Oxide red, casks	lb.	10 - 14
Para toner, kegs	lb	1 00 - 1 10
Vermilion, English, bbl.	lb.	1 30 - 1 32
Yellow, Chrome, C P bbls	lb	20 - 21
Ocher, French, casks	lb.	.02½ - 03

Waxes

Bayberry, bbl	lb.	$0 28 - $0 30
Beeswax, crude, bags	lb.	.20 - 21
Beeswax, refined, light, bags	lb	32 - 34
Beeswax, pure white, cases	lb.	40 - 41
Candelilla, bags	lb.	23 - .24
Carnauba, No 1, bags	lb	42 - .43
No. 2, North Country, bags	lb	23 - .23½
No. 3, North Country, bags	lb	19 - 19½
Japan, cases	lb.	16½ - 16¾
Montan, crude, bags	lb	.04½ - .04¾
Paraffine, crude, match, 105-110 m p	lb.	.04 - .04¼
Crude, scale 124-126 m p., bags	lb	02¾ - 03
Ref., 118-120 m p, bags	lb.	03½ - 03¾
Ref, 125 m p, bags	lb.	03½ - .03¾
Ref, 128-130 m p, bags	lb.	.04 - .04¼
Ref., 133-135 m p, bags	lb.	.04½ - .04¾
Ref, 135-137 m p, bags	lb.	.05 - .05¼
Stearic acid, sgle pressed, bags	lb.	.13½ -
Double pressed, bags	lb.	.14½ -
Triple pressed, bags	lb.	.15½ - .16

Fertilizers

Ammonium sulphate, bulk, f o b works	100 lb	$3 25 - $3 30
F.a.s double bags	100 lb.	3 85 - 3 90
Blood, dried, bulk	unit	4 25 -
Bone, raw, 3 and 50, ground	ton	27 00 - 30 00
Fish scrap, dom, dried, wks	unit	4 00 -
Nitrate of soda, bags	100 lb	2.60 - 2 65
Tankage, high grade, f.o.b. Chicago	unit	3.25 - 3 50
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$4 00 - $4.50
Tennessee, 78-80%	ton	8 00 - 8 25
Potassium muriate, 80%, bags	ton	34 55 -
Potassium sulphate, bags basis 90%	ton	43 67 -
Double manure salt	ton	25 72 —
Kainit	ton	7 22 —

Crude Rubber

Para—Upriver fine	lb.	$0 27½ -
Upriver coarse	lb.	22 -
Upriver caucho ball.	lb	.25 -
Plantation First latex crepe	lb.	27½ - 27¾
Ribbed smoked sheets	lb.	.27½ - 27¾
Brown crepe, thin, clean	lb.	.26½ - 26¾
Amber crepe No 1	lb.	26½ - 27

Gums

Copal, Congo, amber, bags	lb.	$0 12 - $0 13
East Indian, bold, bags	lb.	23 - 23½
Manila, pale, bags	lb.	.20 - 20½
Pontinak, No 1 bags	lb.	20 - 20½
Damar, Batavia, cases	lb.	.28 - .29
Singapore, No 1, cases	lb	34 - 35
Singapore, No 2, cases	lb.	23 - 24
Kauri, No 1, cases	lb.	64 - 65
Ordinary chips, cases	lb.	18 - 20
Manjak, Barbados, bags	lb.	09 - 09½

Shellac

Shellac, orange fine, bags	lb.	$0 68 -
Orange superfine, bags	lb.	.70 - .71
A. C. garnet, bags	lb.	nominal
Bleached, bonedry	lb.	.76 - .78
Bleached, fresh	lb.	64 - .65
T. N., bags	lb.	62 - 64

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh ton	$500.00 -
Asbestos, shingle, f.o.b., Quebec	sh. ton	$65.00 - $85.00
Asbestos, cement, f.o.b., Quebec	sh. ton	20.00 - 25.00
Barytes, grd., white, f.o.b. mills, bbl	net ton	16.00 - 20.00
Barytes, grd., off-color, f o b. mills bulk	net ton	13.00 - 15.00
Barytes, floated, f.o b. St Louis, bbl	net ton	28 00 -
Barytes, crude f o b. mines, bulk	net ton	10.00 - 11 00
Casein, bbl, tech	lb.	21 - .25
China clay (kaolin) crude, f.o.b Ga	net ton	7 00 - 9 00
Washed, f o b Ga.	net ton	8 00 - 9.00
Powd, f o b Ga	net ton	14 00 - 20 00
Crude f o b Va	net ton	8 00 - 12 00
Ground, f o b Va.	net ton	14 00 - 20 00
Imp, lump, bulk	net ton	15 00 - 20 00
Imp, powd	net ton	45 00 - 50 00
Feldspar, No 1 pottery	long ton	6 00 - 7 00
No 2 pottery	long ton	4 00 - 5 50
No. 1 soap	long ton	7 00 - 7 50
No 1 Canadian, f o.b. mill	long ton	20 00 - 22 00
Graphite, Ceylon, lump, first quality, bbl	lb	06½ -
Ceylon, chip, bbl	lb.	05½ -
High grade amorphous crude	ton	15.00 - 35.00
Gum arabic, amber, sorts, bags	lb.	.15 - 16
Gum tragacanth, sorts, bags	lb	.50 - .60
No 1, bags	lb	1.50 - 1.60
Kieselguhr, f o b Cal	ton	40 00 - 42.00
F o b N Y	ton	50 00 - 55.00
Magnesite, crude, f o.b Cal.	ton	14 00 - 15 00
Pumice stone, imp, casks.	lb	03 - .05½
Dom, lump, bbl.	lb	05 - 05½
Dom, ground, bbl.	lb	06 - 07
Silica, glass sand, f o b Ind	ton	2 00 - 2 50
Silica, sand blast, f o b Ind.	ton	2 50 - 5 00
Silica, amorphous, 250-mesh, f.o b Ill	ton	17 00 - 17 50
Silica, bldg sand, f o b Pa	ton	2 00 - 2 75
Soapstone, coarse, f o.b Vt, bags	ton	7 00 - 8 00
Talc, 200 mesh, f o b., Vt, bags	ton	6 50 - 9.00
Talc, 200 mesh, f o b Ga., bags	ton	7 00 - 9 00
Talc, 200 mesh, f o b Los Angeles, bags	ton	16 00 - 20.00

Mineral Oils

Crude, at Wells

Pennsylvania	bbl	$3 25 - $3 50
Corning	bbl	1 85 -
Cabell	bbl	1 91 -
Somerset	bbl.	1 75 -
Illinois	bbl	1 97 -
Indiana	bbl	1 98 -
Kansas and Oklahoma, 28 deg	bbl	1 20 -
California, 35 deg and up	bbl	1 04 -

Gasoline, Etc.

Motor gasoline, steel bbls	gal	$0 22½ -
Naphtha, V M & P deod, steel bbls	gal	21½ -
Kerosene, ref tank wagon	gal	14 -
Bulk, W W export	gal.	07 -
Lubricating oils:		
Cylinder, Penn, dark	gal.	25 - 27
Bloomless, 30@31 grav	gal.	.20 - .22
Paraffin, pale	gal	28 - .30
Spindle, 200, pale	gal.	.25 - .26
Petrolatum, amber, bbls	lb	.05 - .05¼
Paraffine wax (see waxes)		

Refractories

Bauxite brick, 56% Al_2O_3, f o.b. Pittsburgh	ton	$45-50
Chrome brick, f o.b Eastern shipping points	ton	50-52
Chrome cement, 40-50% Cr_2O_3	ton	23-27
40-45% Cr_2O_3, sacks, f o b. Eastern shipping points	ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f o b Ky wks.	1,000	40-46
2nd quality, 9-in shapes, f.o.b. wks.	1,000	36-41
Magnesite brick, 9-in straight (f o b wks)	ton	65-68
9-in. arches, wedges and keys	ton	80-85
Scraps and splits	ton	85
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48-50
Silica brick, 9-in sizes, f o b. Birmingham district	1,000	48-50
F.o b. Mt Union, Pa	1,000	42-44
Silicon carbide refract brick, 9-in.	1,000	1,100 00

Ferro-Alloys

Ferrotitanium, 15-18% f.o.b. Niagara Falls, N.Y.	ton	$200.00 - $225.00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11½ - .11¾
4-6% C	lb.	.12 - .13
Ferromanganese, 78-82% Mn, Atlantic seabd., duty paid	gr. ton	120.00 -
Spiegeleisen, 19-21% Mn.	gr. ton	40.00 -
Ferromolybdenum, 50-60% Mo, per lb. Mo	lb.	2.00 - 2.50
Ferrosilicon, 10-15%	gr. ton	48.00 - 50.00
50%	gr. ton	95.00 -
75%	gr. ton	150.00 - 160.00

Ferrotungsten, 70-80%, per lb. of W	lb.	$0.90 –	$0.95
Ferro-uranium, 35-50% of U. per lb of U	lb.	6.00 –	....
Ferrovanadium, 30-40%, per lb. of V	lb.	3.50 –	3.75

Ores and Semi-finished Products

Bauxite, dom. crushed, dried, f.o.b. shipping points	ton	$6 00 –	$9.00
Chrome ore Calif. concentrates, 50% min Cr_2O_3	ton	22 00 –	23.00
C i f Atlantic seaboard	ton	20 50 –	24 00
Coke, fdry, f o.b. ovens	ton	7 00 –	7 50
Coke, furnace, f o b. ovens	ton	6 00	6.50
Fluorspar, gravel, f.o.b. mines' Illinois	ton	20.00 –	21 50
Ilmenite, 52% TiO_2	lb.	01½–	.01¾

Copper bottoms	30 75
Copper rods	25.25
High brass wire	19 37½
High brass rods	17 00
Low brass wire	21.10
Low brass rods	22 00
Brazed brass tubing	24 25
Brazed bronze tubing	29.00
Seamless copper tubing	25 25
Seamless high brass tubing	23 50

OLD METALS—The following are the dealers' purchasing prices in cents per pound.

Copper, heavy and crucible	11 60@11.80
Copper, heavy and wire	11 50@11.60
Copper, light and bottoms	10 00@10.10
Lead, heavy	5 75@ 6 00
Lead, tea	3 50@ 3 75
Brass, heavy	6 50@ 6 75
Brass, light	5.75@ 6 00
No. 1 yellow brass turnings	6.75@ .700
Zinc	3.75@ 4.25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$3.29	$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

Arkansas

FORT SMITH—The Fort Smith Fertilizer Co., recently organized, has plans under way for the erection of a new 1-story plant for commercial fertilizer production Grinding, mixing, drying and other machinery will be installed Walter Knight is president

California

EXETER—John F Hamburg, an official of the Engels Copper Mining Co., Mills bldg., San Francisco, is at the head of a new company now being organized to construct and operate a cement manufacturing plant on site selected near Exeter It will consist of a number of buildings and is estimated to cost more than $2,000,000, with machinery William F. Humphrey, attorney, Mills Bldg., San Francisco, represents the new company.

REDDING—The Swayne Creosoting Co., plans for extensions and improvements in its plant, including the installation of additional equipment

MERCED—The Yosemite Cement Co., recently organized, is having plans prepared by the Hunt Engineering Co., Kansas City, Mo., for the erection of a new mill on 1,500-acre site acquired on the Merced River, near Merced. It will cost approximately $1,000,000, with machinery The Agricultural Lime & Composite Co., American National Bank Bldg., San Francisco, is interested in the project J E Monroe is an official of the company.

SOUTH SAN FRANCISCO—The Metal & Thermit Corp., Swift St., is taking bids for the erection of the initial units of its proposed new plant on site recently acquired, and will commence work at an early date. It will cost in excess of $1,500,000, with machinery. Headquarters are at 120 Broadway, New York The engineering department, 1127-29 Western Ave., Pittsburgh, Pa., Frank I Ellis, is in charge

Connecticut

MANCHESTER—The Oxford Soap Co has work in progress on a 3-story addition, 60x150 ft, to be equipped as a feldspar-grinding mill and will commence the machinery installation at an early date Complete pulverizing equipment will be installed Other extensions and improvements are contemplated for considerable increase in output.

Florida

TAMPA—The Tampa Bay Fertilizer Co., recently organized with a capital of $1,000,000, is perfecting plans for the operation of a local plant. S W Allen is president.

Illinois

DE PUE—The Mineral Point Zinc Co., Room 1111, 140 South Dearborn St., Chicago, has plans under way for a new smelting plant and general works on local site, to cost in excess of $1,000,000, with equipment. The Leonard Engineering Co., 37 South Wabash Ave., Chicago, is engineer William Scott is president

CHICAGO—The Chicago Bearing Metal Co., 2234 West 43rd St, will immediately commence erection of a new 1-story building at its plant, 35x100 ft, to cost $19,000.

Kansas

WICHITA—The Billings Paint Co. has leased a portion of the new building to be erected at Lulu and Douglas Sts., 80x120 ft., for a new works.

Maryland

HAVRE DE GRACE—The Tiger Tire Co., Toronto, Ont., is completing negotiations with the local Board of Trade for the acquisition of a site for the erection of a new branch plant for the manufacture of ties and rubber goods Property has been donated to secure the plant, which is estimated to cost approximately $200,000, with machinery Plans will soon be drawn.

HAGERSTOWN—The Tanners' Hide & Tallow Co has commenced the rebuilding of its local plant, destroyed by fire a number of months ago, and plans for the installation of machinery at the earliest date, to include melting equipment, presses, grinders, etc.

BALTIMORE—The Standard Sanitary Mfg. Co., Bessemer Bldg., Pittsburgh, Pa., has authorized the immediate preparation of plans for the initial unit of its proposed new enameled products plant on site lately acquired on 5th Ave. It will consist of a number of buildings, estimated to cost in excess of $1,000,000 with machinery.

Michigan

PETOSKEY—The Northwestern Pulp & Paper Co has tentative plans under consideration for the rebuilding of the portion of its local pulp mill destroyed by fire, May 7, with loss estimated at $100,000, including equipment.

Minnesota

ST PAUL—The Waldorf Paper Products Co has awarded a contract to the Steenberg Construction Co, Endicott Bldg., for the erection of its proposed new plant at 2230 Myrtle St., to be 4-story, 84x110 ft., estimated to cost $125,000, with machinery.

Missouri

ST. LOUIS—The Anheuser-Busch Brewing Association, 9th and Pestalozzi Sts., will remodel its malt house and a portion of its stock houses for a plant for the manufacture of glucose and kindred products. The improvement with equipment is estimated to cost $300,000 Work will be commenced at once

CAPE GIRARDEAU—The Marquette Cement Mfg Co, 140 South Dearborn St., Chicago, Ill., has purchased the local plant of the Cape Girardeau Portland Cement Co., for a consideration said to be $2,000,000. The new owner will take immediate possession and will develop plans for extensions and improvements to increase the present capacity.

ST LOUIS—The A. Leschen & Sons Rope Co, 5909 Kennerly Ave., has awarded a contract to James Stewart & Co., Boatmen Bank Bldg., for the erection of a new building at its wire rope manufacturing plant to cost $100,000, to be equipped in part as a testing laboratory

New Hampshire

DANBURY—The Ford Motor Co., Highland Park, Mich, is planning for the construction of a mill on garnet properties on the Wilmot highway, recently acquired from the Garnet Grit Co., for material for the polishing of plate glass. Pulverizing, grinding and refining machinery will be installed The output will be used at the company glass plant at Glassmere, Pa., comprising the former plant of the Allegheny Glass Co, lately purchased.

New Jersey

NEWARK—The Flood & Conklin Co., 182 Chestnut St., manufacturer of varnishes, etc., has filed plans for the immediate erection of an addition to its plant to cost about $40,000

PERTH AMBOY—The manual training committee of the Board of Education has been authorized to arrange for the purchase of a gas furnace for installation at the local school, to be used in connection with metal casting instruction.

PERTH AMBOY—A company is being organized by Emil Stremlau, Room 209, 217 Smith St., to construct and operate a local oil plant for the manufacture of a gasoline substitute. The initial works will cost about $50,000.

TRENTON—The Mercer Pottery Co., Muirhead Ave., manufacturer of general ware, will commence the erection of a 1-story

addition to cost about $15,000, exclusive of equipment

NEWARK—The Celluloid Co, 209 Ferry St, has completed plans for the construction of a new plant addition for general increase in capacity, estimated to cost $130,000, with equipment

METUCHEN—The Empire Floor & Wall Tile Co, Middlesex Ave, has been secured by new interests and plans are being arranged for the immediate reopening of the plant, which has been inactive for some time past Alterations and improvements will be made in the building and machinery with the installation of necessary operating equipment Roy Schweiker is plant superintendent

CARTERET—The Mexican Petroleum Co will make extensions and improvements in its local oil works, including the erection of new buildings

New York

FORT MILLER—Fire May 6, destroyed a portion of the plant of the Fort Miller Pulp & Paper Co, with loss estimated at $100,000, including equipment. It is planned to rebuild.

GENEVA—The General Glass Co, Inc, recently organized by Rochester, N Y, interests, has acquired the plant of the Geneva Glass Products Co, and will take immediate possession. The new company will expand the factory and purposes to install additional equipment for the production of glass under a recently developed process The company is headed by Henry J. and Earl H Crowder Louis E Fuller Rochester, attorney, is representative

North Carolina

CHARLOTTE—The Ornamental Stone Co, 129 Brevard Court, will commence the erection of a new plant, 75x300 ft, for the manufacture of precast stone products Mixing and grinding machinery, molding apparatus and other equipment will be installed W F McCanless is president, and C J Helms, secretary and treasurer in charge

BEAUFORT—M L Wright, Beaufort, has plans under consideration for the establishment of a local plant for the manufacture of fertilizer products Inquiries are being made for equipment

Ohio

COSHOCTON—The Columbia Tire & Rubber Co, Mansfield O has acquired the local plant of the Midland Tire & Rubber Co, and will use the property as a branch works Extensions and improvements are planned The company will also continue its branch factory at Columbiana, O

LISBON—The American Vitrified Products Co has broken ground for a new 1-story plant to replace its works destroyed by fire early in March with loss of about $100,000 New machinery will be installed The plant is estimated to cost close to $130,000 with equipment

NEWTON FALLS—The Newton Falls Rubber Co, lately organized, has extension and improvement work in progress at the former local plant of the Trumbull Rubber Co, acquired from the receiver, and purposes to have the mill ready for service early in June Equipment will be provided for the employment of about 250 men Irvin Jordan is vice president and general manager

Oklahoma

BARNSDALL—The Barnsdall Refining Co has commenced enlargements in its local oil-refining plant to increase the handling capacity to about 5,000 bbl per day A number of new plant units will be equipped

PONCA CITY—The Marland Refining Co will rebuild the portion of its local oil plant destroyed by fire recently with loss approximating $25,000

Pennsylvania

WARREN—The Conewango Refining Co has tentative plans under consideration for the rebuilding of the portion of its Plant No 1, destroyed by fire, May 7, with loss estimated at $750,000, including machinery The company is operated by the Fred G Clark Co., 1081 West 11th St Cleveland Ohio

PITTSBURGH—The Vitro Mfg Co, 60 Oliffe St, manufacturer of enamels, oxides etc., has filed plans for the erection of a 1-story plant addition, estimated to cost $14,000, exclusive of equipment.

FRANKLIN—Fire, May 7, destroyed a portion of the No. 3 Eclipse refining plant of the Atlantic Refining Co, with loss estimated at $33,000 It is planned to rebuild Headquarters are at 3144 Passyunk Ave, Philadelphia, Pa

PITTSBURGH—The National Tube Co, Frick Bldg has taken title to property on Forbes St, 150x223 ft, to be used as a site for a new research laboratory Plans will be drawn at an early date

PHILADELPHIA—The Phil-Fiber Boxboard Mills, Inc, Delaware and Tasker Sts, has filed plans for the erection of a new 1-story building at its plant to cost about $14,000

ROULETTE—The Roulette Glass Co, Corning, N Y, recently organized with a capital of $1,200,000, is considering plans for the erection of a new plant at Roulette, on site now being selected Dr George S Goff heads the company

Texas

BRECKENRIDGE—The Magnolia Petroleum Co Dallas, is planning for the construction of a new plant on local site for the production of carbon black, estimated to cost close to $200,000, with machinery Application has been made for permission

FORT WORTH—The Transcontinental Oil Co Pittsburgh, Pa, has plans nearing completion for the erection of an addition to its local refinery, to include the installation of a new unit for gasoline manufacture stills and other equipment, estimated to cost $500,000 O D Robinson is vice president

FORT WORTH—The Texhoma Oil & Refining Co, Wichita Falls, Tex, is planning for the erection of a new local plant for gasoline refining It will consist of 4 units each with capacity of 500 bbl a day, estimated to cost close to $500,000, with machinery W B Hamilton is president

TEXAS CITY—The Marland Refining Co, operating a local oil storage and distributing works, has preliminary plans under consideration for the erection of an oil refinery in the vicinity of its present works, estimated to cost in excess of $250,000, with machinery

EL PASO—Wells, Stillwell & Spears, Inc, has plans nearing completion for the construction of a cotton oil mill, to cost approximately $90,000 The equipment will be electrically operated

West Virginia

MORGANTOWN—The United States Window Glass Co has plans for the installation of additional machinery at its local plant including gas producers and other equipment Extensions will be built A portion of a bond issue of $350,000 now being sold will be used for the expansion Walter A Jones is president

New Companies

LAUBEC CHEMICAL PRODUCTS CO, New York, N Y, chemicals and chemical byproducts, $25,000 Incorporators H Laub, C Heckelman and H Becker Representative Herman Gottlieb, 299 Broadway

CAPE OIL CO, Boston, Mass, refined oils, $3,750,000 Henry L F Kreger, president and Robert Cutler, treasurer, both of Boston

J M BOOTH CHEMICAL CO El Paso Tex, chemicals and chemical byproducts, $10,000 Incorporators J M Booth, and W H Pryor, both of El Paso

JOHNSON-CARTER CORP, Newark, N J.; celluloid and composition products, $500,000 Incorporators Peter and Charles Johnson, George Y Carter Representative Porter, Link & Lafferty 31 Clinton St Newark.

ELECTROLYTIC ZINC PROCESS CO, Butte, Mont, chemical and metallurgical operations, $10,000. C. F Kelley, Butte, heads the company.

NEWMAN PRODUCTS CORP, 526 West 18th St, Chicago, Ill, chemicals and chemical byproducts, $10,000 Incorporators: John Newman, G Arthur Buhl and George S Pines

GOOD RUBBER CO, Akron, O; rubber products, $10,000 Incorporators W D and E K Good, both of Akron

McCALL OIL CO, Oakland, Calif, petroleum products, $125,000 Incorporators: B B McCall Sr and Jr, and H. E Peterson. Representative: Roscoe D. Jones, Bank of Italy Bldg., San Francisco

NORRIS FERTILIZER CO, Wilmington, Del; fertilizers: $40,000. Representative. Corporation Service Co, Equitable Bldg., Wilmington.

MOKAN CHEMICAL CO, Kansas City, Mo, chemicals and chemical byproducts; $10,000. Incorporators F I and Searcy Ridge, both of Kansas City.

ETTINGER-SMITH CHEMICAL CO, 3763 Wabash Ave, Chicago Ill, organized; chemicals and chemical byproducts. Bernard and Michael Holtzman are heads,

LEMA TANNING CO, Salem, Mass.; operate a leather tannery, $25,000 Paul Harsfald is president, and Morris H Levins, Dorchester, Mass, treasurer and representative.

ATLAS ROCK SALT CO, Wilmington, Del, salt and derivatives, $100,000 Representative: Corporation Trust Co of America, du Pont Bldg., Wilmington.

SEABOARD CRYSTAL CO., Newark, N J; chemicals and chemical byproducts, $100,000 Incorporators: James F. McKenna John M. Williams and John F. Burrell, 67 Stockton St, Newark. The last noted is representative

UNIVERSAL GYPSUM CO., Rotan, Tex., gypsum products; $100,000. Incorporators C E Williams, L Ford and J. B Gray, all of Rotan

NORTHEASTERN CONCRETE TILE CO, Worcester, Mass, concrete and cement products, 500 shares of stock, no par value Isaac M. Freedman is president, and N A Fieldstad, Worcester, treasurer and representative

TRIBOROUGH CHEMICAL CORP., Wilmington, Del., chemicals and chemical byproducts, $20,000 Representative: Corporation Service Co, Equitable Bldg., Wilmington

ALPINE OIL CO, San Francisco, Calif, refined petroleum products, $50,000. Incorporators S Herbert Lanyon, W. S. Boggs and C L. Froding Representative Thomas J Straub, 445 Sutter St, San Francisco.

RALEIGH ASBESTOS & SHINGLE CO., 217 Pullen Bank Bldg, Raleigh, N C.; asbestos and composition products, $100,000 Incorporators Perrin Busbee, D H. Winslow and C. F. Koonce

NAKLO CO, Rumford, Me, chemicals and chemical byproducts, $200,000. William J Leader is president, and J Abbott Nile, treasurer, both of Rumford Representative: Ralph T Parker, Rumford

REILLY-WHITEMAN CO, Philadelphia, Pa., being organized to manufacture chemicals and chemical compounds Application for a state charter will be made May 28 Representative: Frank A Moorshead, Commonwealth Bldg, Philadelphia

SUPERIOR OIL CO, Sandusky, O, refined oils; $100,000 Incorporators Martin J Monahon and Albert J Sanders, both of Sandusky

NEW ENGLAND PORCELAIN CO, Boston Mass; porcelain products, $100,000 Horatio C Rohrman, president, and H Wray Rohrman, Winchester, Mass, treasurer and representative

BLEKRE TIRE & RUBBER CO, St Paul, Minn., rubber products, $475,000 E O Blekre, 5025 Colfax Ave South, Minneapolis, Minn, heads the company

Opportunities in the Foreign Trade

Parties interested in any of the following opportunities may obtain all available information from the Bureau of Foreign and Domestic Commerce at Washington or from any district office of the bureau The number placed after the opportunity must be given for the purpose of identification.

OILS, TECHNICAL AND EDIBLE; fats, greases, tallows (raw materials and manufactured products thereof) Rotterdam, Netherlands Agency.—6340

OIL CAKES, FOODSTUFFS, etc, of the best quality. Malmo Sweden Agency.—6345.

CHEMICALS, PERFUMERY, HARDWARE, etc Capetown, South Africa. Agency.—6346

ROSIN AND TURPENTINE Genoa, Italy. Agency — 6400.

BLACK DECOLORANT FOR BLEACHING PURPOSES Turin, Italy. Agency —6401

DRUGS, CHEMICALS AND TOILET ARTICLES Winnipeg, Canada Purchase and agency —6402.

FERTILIZERS AND CHILEAN NITRATE Mannheim, Germany. Purchase —6403

CHEMICALS, DRUGS AND DRUGGISTS' SUNDRIES. Winnipeg, Canada Purchase.—6405.

CRUDE SULPHUR, 99 per cent and copper sheets, 4x4 ft., of various thicknesses and weights. Karachi, India. Purchase —6406.

PAINTS. Johannesburg. South Africa. Exclusive agencies.—6420.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, May 28, 1923 *Number* 21

Christening a New Technology

APPROXIMATELY a billion dollars is expended annually by industry for products of mine or quarry in which the metal content is of little or no significance. Fluorspar, talc, feldspar, mica, gypsum, salt, graphite, sulphur and scores of other mineral products are attaining constantly increasing industrial importance and the consuming industries are requiring that more and more skill and care be used in their preparation. For many of these products this refining process goes far beyond those limits of milling or concentration that for non-metallic minerals would correspond to the ore dressing of metal-bearing ore. And this further preparation, which demands close control of chemical as well as physical properties of the product, calls for a new type of supervision and research. In the field of the metallic minerals this is the sort of service that is rendered by metallurgy. But obviously the metallurgist of orthodox training and common experience is not suited to supervise this work in the case of the non-metallics. The mining engineer is almost never enough of a chemical engineer to do the job with thorough satisfaction. It can scarcely be questioned, therefore, that there is real need here for a new group of technologists skilled in the science and engineering of the non-metallics.

The Bureau of Mines in the establishment of its new experiment station at Rutgers College, New Jersey, very properly recognizes these facts, for the new station will specialize in problems of producing and utilizing the non-metallic minerals. Dr. OLIVER BOWLES, who has been designated to head this new station, is eminently fitted for the task to which he has been appointed. He has studied many of these problems and has offered valuable guidance to numerous non-metallic industries. He represents precisely the type of specialist that must grow up in all of these lines if we are to have the maximum efficiency in the utilization of these valuable natural raw materials.

There is a wealth of these resources in the United States and in most cases we have been prone to look upon the supplies as inexhaustible. But, however abundant the supply may seem to be, the maximum skill used in the preparation of these raw materials for the chemical engineering industries will be well worth while. The direct saving in production cost per unit of quantity may not be great, but the usefulness and real value of the product will inevitably be increased. The production wastes which are eliminated and the by-products which are developed will doubtless more than pay the producing industries for their increased investment in supervision and research.

A Little Homily on The Man in the Works

AN AMERICAN ENGINEER resident in England has invented a mechanical system of treating numbers algebraically that is almost uncanny in what it accomplishes. It bids fair to throw a large number of clerks out of employment. At first glance that seems a pity, but in the end it may be a good thing for the clerks. Except in the light of tradition, is there really any distinction in a white collar job? Suppose it leads to a post of administration, how many men are competent in administration? They are very rare. And what kind of a life is more miserable than a position which the incumbent is not equipped to fill? Most of the young men in the office settle down later to posting letters or copying off figures or operating an adding machine—a class of work that is but little above the rank of unskilled labor.

We think the young man has a better chance if he goes into the works. There he can find himself. If he has mechanical skill, he has, under intelligent industrial administration, the opportunity to develop it. If he has the art of getting along with men, that, too, will soon come to the fore. If he has the mental equipment to be a good salesman, he is learning what other salesmen never learn: the strategems of manufacture and what the works can turn out with ease as well as the things that will cause trouble in production. In other words, he learns which are the most profitable wares to sell. And in the long run he is better paid.

Suppose he wants to improve his mind and to develop the graces of life. His work is over when the whistle blows, and all that is best in literature and art is his for the asking. Scarcely any private library or gallery is equal in scope at least to the public libraries and municipal galleries. There is nothing to hinder him from being a gentleman in appearance, in speech and in habit of mind.

Let's hark back to the medieval days when the guilds of craftsmen, of men who worked with their hands, were flourishing. The greatest treasures in art today are the work of those very men. There is nothing to prevent the craftsman of today from advancing, unless it be his native inhibitions or some unfortunate family connections.

The president, the secretary, the treasurer, the chief engineer and the general superintendent have no rest. Theirs is the worry about credits, about getting in materials, about making shipments, getting cars for loading, and finding new markets. Some of them may get around a bit later in the mornings, but their work is never done. Not one competent executive in a thousand can really shed his cares when he leaves the office.

His leisure is a respite from worry and he needs a frivolous musical comedy or a game of golf for his diversion. But the man in the works who takes off his jumper and washes up when the whistle blows can find a grassy spot under a greenwood tree and read to his heart's content in warm weather, or he can hear concerts, see the best plays, rejoice that PINERO has come back and admire JANE COWL in *Juliet*—in short, the beautiful things of life are his in response to his resolution to avail himself of them. There is no occasion for him to tie himself down to the movies or to literature for lazy minds or to hang around the drug store. He can leave that to the white collar boys in the office. Most of them are booked for the Vale of Discontent.

Why Not Make Our Own Synthetic "Valuables"?

OPPORTUNITY for the expansion of a domestic industry, in the face of foreign competition, depends largely on the difference between the foreign value of imported merchandise and the price at which it is sold to the American consumer. Last year the Treasury Department and the Senate Finance Committee undertook a joint investigation. The appraiser of merchandise at the port of New York was instructed to report the facts in regard to the country of origin, foreign value, transportation and other charges, duty paid and total landed cost of sundry articles purchased in New York City by representatives of the Finance Committee.

The investigation was carried out in a businesslike manner. The itemized data of the landed cost were prepared from invoices and entries on file at the Customs Office. The articles, after purchase by a customer unknown to the retailer, were inspected at the appraiser's office and identified by the examiners who usually pass on such merchandise. The results, as set forth in a Senate committee print, offer convincing proof in these particular instances of the vast "spread" between foreign value and American retail price, between the total landed cost and the amount paid by the consumer.

The articles purchased included necessaries and luxuries. In the latter class we note the cost in the United States of what was presumably a string of imitation amber beads, made in Germany and valued there at 62 cents. Charges, including transportation, insurance and freight, amounted to 1.6 cents; duty, 12.4 cents—making a total landed cost in the United States of 76 cents. The necklace was purchased from Gimbel Bros., of New York, on June 6, 1922, the price being \$12.50. This shows an increase in retail cost over landed price of 1,544 per cent!

The profits made by New York retailers on "pearls" are much more modest, to judge from statistics. A necklace of these was valued in France, the country of origin, at \$12.25. Charges, including transportation, insurance and freight, aggregated 98 cents; duty, \$4.28—making a total landed cost in the United States, including 75 cents for an American-made clasp, of \$18.26. The article was purchased from B. Altman & Co., of New York, on May 31, 1922, the price being \$150. In this instance the percentage of retail price to landed cost was a paltry 757 per cent!

These facts should spur the efforts of American inventors and technicians who realize that a demand exists here for imitation gewgaws of all types. The labor cost to make beads and artificial jewelry is not great. The problem is one rather of the application of the science of glassmaking and the mechanics of production. At present the only persons in the United States who seem to be benefiting from the demand are the retailers.

White Tiles In Black Places

CLEANLINESS may be next to godliness—yet someone has said that in the average chemical plant it is often "next to impossible." We were inclined to that view ourselves until the other day we had the pleasure of going through the byproduct house of a modern coke-oven plant in a large Middle Western city. The things that impressed us most were that the walls were tiled in white and both the floors and the walls were actually clean. Now a byproduct house is generally far from inviting, for the manufacture of ammonium sulphate is ordinarily accompanied by rather dirty conditions. But things were different in this case. The white tiles not only improved lighting conditions tremendously but they seemed to establish a high standard of cleanliness—and the management had lived up to this standard.

But, you may ask, is it not an added burden rather than a help to management to be compelled to maintain this state of affairs? If you think so, perhaps you have not taken into account the psychological effect of such surroundings. Is it not a fact that men when forced to be clean about their work will also be careful? And we should not forget that particularly in the chemical plant the careful operator is the jewel of greatest price.

There is a thought here that all of us might well keep in mind: Make the men clean up the drip or sludge under the machines and wash the splatters off the walls. Their self respect and consequently the quality of their work will be improved in the process, and you, Mr. Manager, will realize dividends in an easier and more profitably operated plant.

Opportunities for The Inventive Mind

ON BEHALF of the British Institute of Patentees Sir WILLIAM BELL has recently made public a list of suggestions embracing the major inventions most needed by the world. A glance through this comprehensive compilation brings home with fresh emphasis the important rôle of the chemical engineer. Of a dozen problems which one reviewer has selected at random from this list, more than half may be said to lie within the fields of chemistry and engineering. Nor could any one of them be approached intelligently without a fair appreciation of the principles of these sciences. A bendable glass, a flannel fabric that will not shrink, a road-surfacing material that will not be slippery even when wet, an efficient heating furnace—these are but a few of the problems awaiting solution.

It is not our purpose to glorify the chemical engineer unduly or to magnify the importance of his work as it relates to his fellow men. His responsibilities to progress are admittedly large; the present list is but a confirmation of this fact. It merely catalogs a few of the opportunities awaiting evolution into reality by the creative minds of our profession.

The Significance of Industrial Hydrogen

AN EDITORIAL INTERVIEW WITH DR. H. S. TAYLOR OF PRINCETON UNIVERSITY

THREE great fields for industrial hydrogen are aëronautics, hydrogenation processes and nitrogen fixation—i.e., synthetic ammonia.

If dirigible airships come into general use, it is scarcely likely that they will be lifted by helium except in war time. They may be partly lifted by it by inclosing an inner bag of hydrogen in an envelope of helium, but the principal lifting medium will probably be hydrogen. A modern dirigible airship requires two and three quarter million cubic feet of gas, which is the contents of a very large municipal gasometer. Hydrogen becomes explosive in a mixture with helium when the concentration reaches 15 per cent.

Hydrogenation processes also call for large volumes of the gas. Professor TAYLOR has spoken of a single factory that daily consumes over 800,000 cubic feet of hydrogen.

Fixation of nitrogen bids fair to demand the largest supply when once the synthesis of ammonia is properly mastered. To produce one short ton of ammonia requires 80,000 cubic feet of hydrogen. To multiply the entire number of tons of ammonia needed for fertilizer by 80,000 gives one a notion of the tremendous volume of hydrogen needed for this purpose alone.

The processes available for producing hydrogen are five: (1) The steam-iron contact process. (2) Water-gas catalytic process, in which water gas—i.e., hydrogen and CO—pass with steam over a catalyst at 500 deg. C., giving hydrogen and carbon dioxide. (3) Liquefaction, in which the CO of water gas is liquefied, freeing the hydrogen. (4) Electrolytic decomposition of water. (5) Thermal decomposition of hydrocarbons.

We cannot say that any one process is the best. In water-gas catalysis, for instance, there is a remnant of about 4 per cent of nitrogen that persists as a mixture and cannot be economically removed in the present state of the art. This is of no consequence in ammonia synthesis, because nitrogen is one of the reacting substances and more must be added. But in the hydrogenation of oils it is a diluent, and a very troublesome one at that. So the cheapness of water-gas catalysis hydrogen must be discounted in hydrogenation.

Electrolysis of water gives us the purest hydrogen, but it is also expensive unless the producer has a good market for the oxygen that is made with it. One large hydrogenating works began with the steam-iron catalytic process, but, finding a market for oxygen, has gone over very profitably to the purer hydrogen from electrolysis of water.

The thermal decomposition of hydrocarbons, the process described in the three articles by E. R. WEAVER of the Bureau of Standards which are now appearing in *Chem. & Met.*, has not been employed to a large extent thus far in the hydrogen industry. Among the principal difficulties has been the high temperature required for the complete decomposition of the more stable compounds such as CH_4 which are always produced in cracking and which unless removed become troublesome inerts or diluents. Mr. WEAVER'S work promises to solve the problem. Another difficulty, mentioned in the paper, is the production of carbon monoxide due to oxidation-reduction reactions which occur in the cycle. This is minimized by attention to the purity of materials used in construction of the equipment, the absence of iron and the elimination of moisture and oxygen from the oils used. Mr. WEAVER'S contribution is pioneer work of leading importance, but it may be said that all the other hydrogen processes need the same kind of intensive study. Each of the other systems should yield improvements under such research, and until this is done it is scarcely fair to make comparisons. It is the opinion of Professor TAYLOR that the steam-iron contact process is a very promising field for such investigation and that it could be improved materially in output of hydrogen per unit of raw material (coke and steam) and in the engineering features of the layout. There has been little improvement over the original unit built by HOWARD LANE in England early in this century. The German modification of the Lane process which substitutes one retort for thirty-six has been introduced, and economies are claimed for it, but putting thirty-six retorts into one is scarcely a radical change, and the economic difference between the two types cannot be great. What is needed in this case is fundamental study and then the creation of new designs.

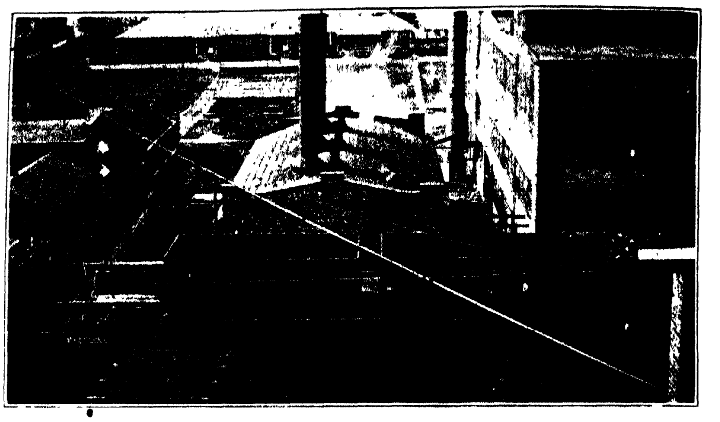
It is encouraging, however, to be able to record the results of fundamental study in at least one of the five important processes for hydrogen production. Only when similar data are available for each of the other systems will it be possible to show which of the methods will be of the greatest significance in the large-scale production of this gas so essential to war- and peace-time industry.

Dr. Hugh Stott Taylor, whose views on the industrial significance of hydrogen are reflected in this interview, is professor of physical chemistry at Princeton University. He is an Englishman, born in Lancashire in 1890, and a former student of Arrhenius at the Nobel Institute, Stockholm. Later he studied at the Technische Institut at Hanover and at the University of Liverpool. In 1914 he came to Princeton, where, except during his war activities, he has been ever since. Of late he has been addressing himself in research to catalysis and more particularly to the adsorption of gases by catalytic agents. All cases of contact catalysis, he believes, are preceded by an association of the reacting substances with the contact catalyst. This adsorption is just as specific as catalysis. Dr. Benton of Princeton has shown, for example, that CO can be oxidized in a mixture of 1 part in 99 of H_2. The reason is that while the relation of H_2 to CO is as 99:1, the concentration of gases on the surface of the catalyst is almost wholly CO, with no H. "The CO oxidizes first because the H_2 doesn't get a look-in," says Professor Taylor.

Route Your Materials Via Air Line

By F. L. Jorgensen
President, Dust Recovery & Conveying Co.
Cleveland, Ohio

A short study of the art of pneumatic conveying. Classification of the various systems in use Examples of successful installations. How abrasives are handled



AN AIR LINE LIME CONVEYOR

PNEUMATIC material conveying has been in use for a considerable time. Although until recently only a few materials have been successfully handled, engineering progress in the last few years has increased the field of this method and made it an important factor in the material-handling world. In this article, brief mention will be made of the various systems of pneumatic conveying in use and many examples will be given of installations in various fields, installations that have solved labor difficulties, cut costs and improved conditions generally.

Pneumatic conveying systems naturally fall into two main classifications—the pressure or blowing system and the vacuum or suction system. In recent years the vacuum system, into which classification most of the examples cited here fall, has taken the lead.

The two main classifications mentioned above have three subdivisions each, depending on the pressure under which the system operates. Thus the completed classification is: Vacuum systems—low, medium and high; pressure systems—low, medium and high.

Of the above, the low-pressure or the low vacuum system is, with few exceptions, exclusively used in dust-collecting work and is mentioned here only to make the outline complete. These systems are in some cases used for conveying sawdust, shavings, wool, feathers and similar lightweight materials. The systems work generally with a pressure or vacuum of 6 to 10 in. of water. A comparatively large air volume is required, ranging from 30 to 70 cu.ft. of air per pound of material handled, depending on the nature and weight of the material and the distance over which it must be conveyed. Fans are used for this work.

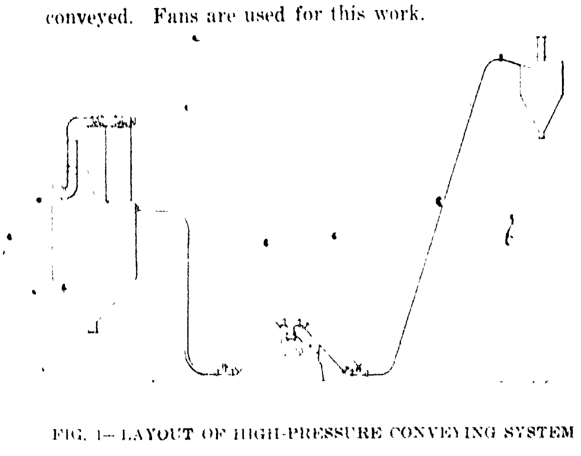


FIG. 1—LAYOUT OF HIGH-PRESSURE CONVEYING SYSTEM

The medium-pressure and medium-vacuum systems have been used extensively for many years, especially for handling grain and similar materials. These systems have successfully solved many handling problems of this nature. Rotary blowers or vacuum pumps supply the energy and 4 to 10 in. of mercury is the pressure or vacuum used. In general design these systems resemble the high-pressure and high-vacuum systems. However, as they use a larger volume of air, they also use larger pipe lines and collecting stations than do the high systems. From 3 to 10 cu.ft. of air per pound of material handled is required, depending on the nature and weight of material handled and the distance which the material is conveyed. They will handle, however, the same materials as the high systems, subject to certain disadvantages which will be pointed out later.

The High-Pressure System

As stated above, pneumatic conveying has been used for years for handling materials that had little or no dust in them, such as grain, and where it was immaterial if part of the dust were discharged with the air. This was because there had been no efficient dust-collecting plant as yet developed. Now such equipment has been perfected and the field of pneumatic conveying has thus been enormously enlarged.

In so far as equipment is concerned, this high-pressure system is the simplest of all. It consists of a high-pressure blower, a pipe line and a collector. The material can be fed into the pipe line either through a specially designed feeder or through an ejector. When materials containing little or no dust such as grain, wood chips, whole pepper or the like are handled, the material can simply be blown through the pipe line into a cyclone or directly into a bin or warehouse. This is illustrated on the right-hand side of Fig. 1.

Where, however, dusty materials such as soda ash, plaster of paris, cement, etc., are conveyed, the equipment must include in addition an air filter to prevent the dust being carried away with the escaping air, thus eliminating waste and nuisance. This is shown on the left side of Fig. 1.

The use of this pressure system is in practice generally limited to problems where the material to be conveyed can be fed into fixed receiving stations at stationary points, and the rapidly increasing use of pneumatic conveying in late years has mainly been due to the suction system. With this system, because a flexible feeding hose can be used and pipe lines can be

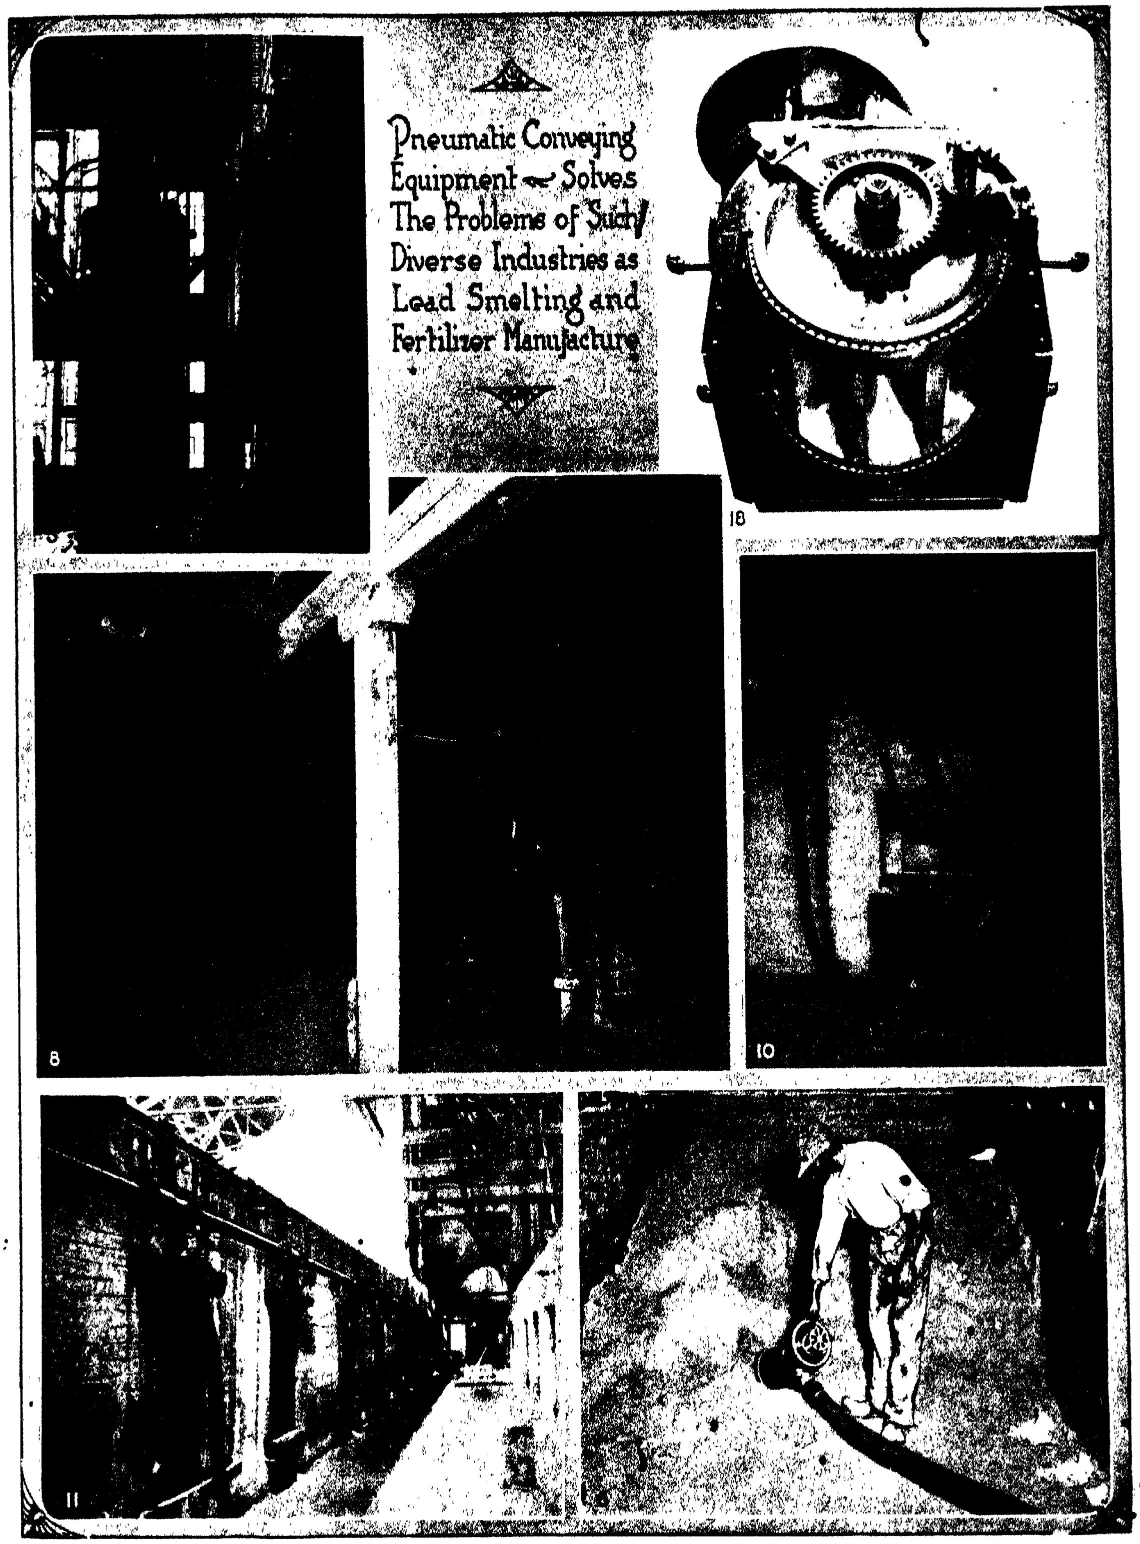

Fig. 3—View of equipment for handling lead. Fig. 18—Rotary discharge lock. Fig. 8—Collecting station. Lithopone-conveying equipment. Fig. 10—Intake at lithopone crusher. Fig. 11—System for handling dust from settling chambers. Fig. 6—Unloading a car of fertilizer. (Note the relatively clean conditions and absence of dust.)

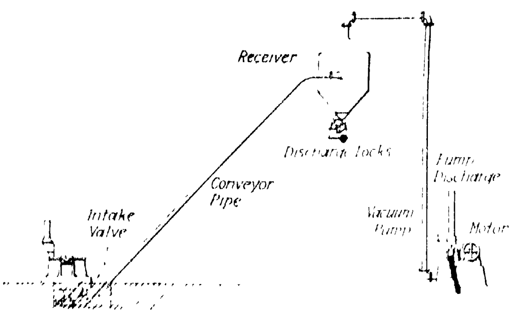

FIG. 2—LAYOUT OF HIGH VACUUM CONVEYING SYSTEM

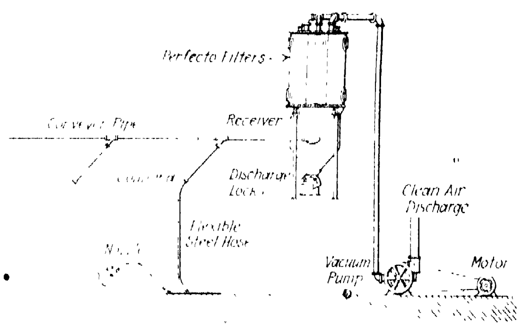

FIG. 3—LAYOUT OF SYSTEM WITH DUST FILTRATION

run from the same collecting station to various points, a greater flexibility and hence adaptability is attained.

During the war it became extremely difficult to get material for sacks. For this reason such materials as cement, soda ash, gypsum, lime, etc., very often had to be shipped in bulk in box cars. This practice has developed from an emergency measure to a common method of shipment because of the economy which it effects. But shipping in this manner does make it hard to unload the cars by the methods formerly in use. The need for an economical unloading device is met, however, by the pneumatic conveying system and today this use of the equipment is the field in which it is most employed.

When mentioning the subject of car unloading, we at the same time strike the essential difference in the adaptability of the medium-vacuum system in comparison with the high-vacuum system. With the medium-vacuum system an air volume of from 3 to 10 cu.ft. per pound of material is required with vacuum at 4 to 10 in. Hg. This necessitates (to make a concrete illustration) using a 10-in. pipe and suction hose for unloading 20 tons per hour from a car conveying material a distance of, say, 150 ft., using an air volume of 4,000 cu.ft. per minute and with a vacuum of 8 to 10 in. Hg; while under the same conditions and with the same capacity and distance, the high-vacuum system would require only 1,600 cu.ft. of air per minute at 16 to 17 in. Hg vacuum and only a 4-in. conveying pipe and hose. It will be very easy for everybody to understand the difference between handling a 10-in. heavy suction hose in a car in comparison with a 4-in. hose; the difference being that the one is nearly impossible and the other is practical. This and the dust-collecting efficiency explain the success of pneumatic conveying in late years.

What applies to hose, of course, also applies to pipe lines and size of collecting station and dust collectors; and it will be apparent that a small pipe line is easier to put up almost anywhere than a large cumbersome line. The high velocity and vacuum used have made it feasible to convey the heaviest known materials as well as the lightest; and this system is actually handling such materials as metallic lead from atomizers, which weigh from 450 to 500 lb. per cu.ft.; and such materials as talcum powder, carbon black and powdered coal.

Fig. 2 shows the outlines of a typical pneumatic conveying installation of the simplest form and will illustrate the system as this has been used for many years. It consists simply of a vacuum pump, pipe line and receiver in which the material is precipitated. This equipment in modern practice would be used only on materials free from dust, as dust will not all settle in the receiver, but pass on and be discharged through the pump. This equipment as well as the following

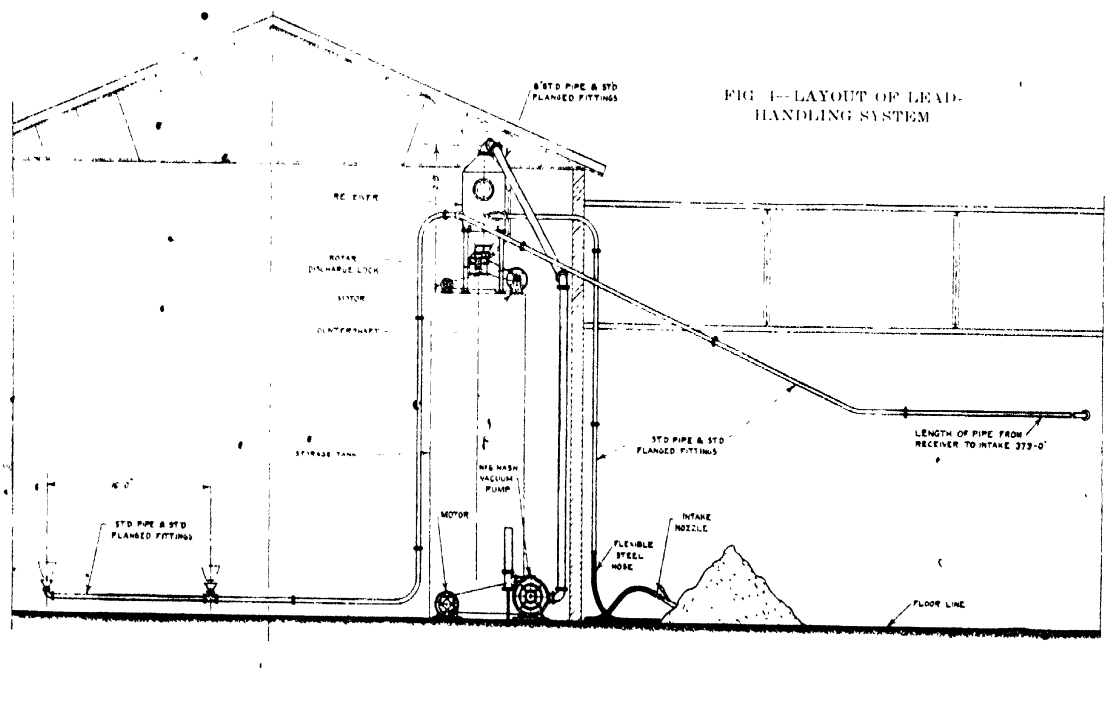

FIG. 4—LAYOUT OF LEAD-HANDLING SYSTEM

Fig. 13—Conveyor for dust from precipitators. Fig. 14—Unloading bauxite. Fig. 12—System for recovery of flue dust. Fig. 16—Unloading pebble phosphate. Fig. 17—Three-valve discharge lock.

described installation can of course be used as well with the medium- as the high-vacuum system. It is only to be borne in mind that the comparative size, for same capacities, will be different, as the high-vacuum system will allow all parts to be considerably smaller.

A typical installation on this order is shown in Figs. 3 and 4. This installation was designed for high-vacuum and conveyed 10 tons per hour of atomized metallic lead from atomizers to storage bins through a 2½-in. pipe. This type of equipment, however, has its widest field in grain handling and when the large elevators or dock legs get to the bottom of the present large tonnage steamers, a 3- to 4-in. flexible suction hose for cleaning up at the rate of 10 to 20 tons per hour saves time and labor. Fig. 4 also serves to illustrate how much space is saved by such an installation in comparison with the corresponding equipment of belt or other mechanical conveyors. This type of application is also ideal for handling material from small boats or for transferring from barges to steamers and *vice versa*. When this method is once fully understood in the shipping world, the demand for such pneumatic conveying equipment will be enormous.

We have previously indicated the quickly increasing demand for equipment for handling dusty materials, either from one place to another in a factory where conditions will not allow any other means, for unloading cars, and for handling poisonous or for other irritating materials. It has been the development of the high-vacuum system with the required small air volume and the perfected dust-collecting equipment which has made it possible to satisfy this demand. In Fig. 5 is shown the general outline of such a system. It is the same in every way as the equipment described immediately above, but automatic self-cleaning dust filters are placed on the top of the receiver and the air when leaving the receiver is filtered in the filter compartments shown. The dust is retained by the filters and periodically and automatically is shaken back into the receiver and discharged with the material through the discharge lock, while the air that now is clean passes on to the pump.

One of the most difficult labor problems, in the fertilizer industry and also in other places, consists in handling disagreeable and dusty materials. Men do not generally care for such work and the resulting labor turnover often assumes serious proportions. Among materials the handling of which is attended by such difficulties, we might mention fertilizer materials like tankage, phosphate, dried blood and bone meal. Materials in other industries include lime, cement, calcium arsenate, salt cake, etc.

In handling this type of material pneumatically the labor problem is mostly solved, for the method does away with the dust problem and its consequences in disagreeable working conditions. In Fig. 6 we see a worker unloading a car of such material. Note how clear the atmosphere is of dust in comparison with the results obtained by hand methods.

In Fig. 7 the layout of such an installation is given, the design being arranged for the unloading of three cars at once. By a multiplication of the 3-in. pipe lines shown, even more cars can be unloaded at once and switching is eliminated. In this particular layout the material from the cars is discharged into an industrial railway for distribution throughout the plant, as the elevation at the right of Fig. 7 shows.

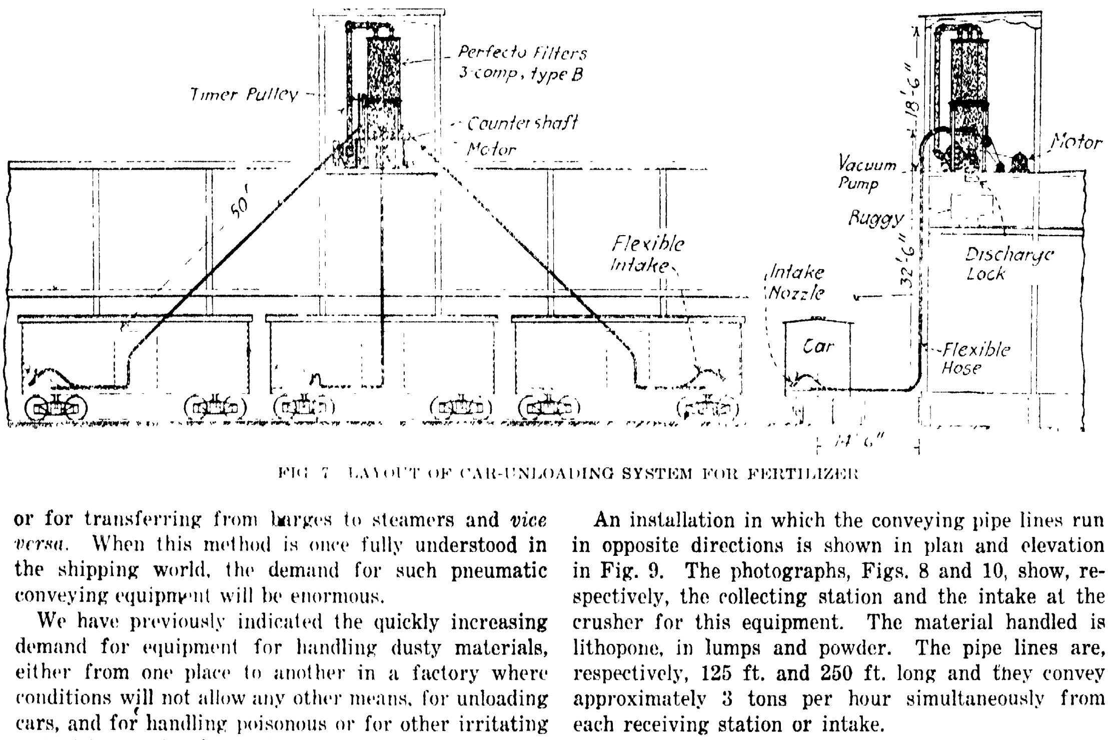

FIG. 7. LAYOUT OF CAR-UNLOADING SYSTEM FOR FERTILIZER

An installation in which the conveying pipe lines run in opposite directions is shown in plan and elevation in Fig. 9. The photographs, Figs. 8 and 10, show, respectively, the collecting station and the intake at the crusher for this equipment. The material handled is lithopone, in lumps and powder. The pipe lines are, respectively, 125 ft. and 250 ft. long and they convey approximately 3 tons per hour simultaneously from each receiving station or intake.

AIR TRANSPORTATION IN METALLURGY

There has recently developed a great interest in pneumatic conveying in many branches of metallurgical industry. This has been accelerated by the pronounced labor shortage in this field. Several installations along this line are now being made for handling arsenic recovered from smelters, dust from powdered coal in annealing furnaces, dust from checkerwork in steel plants and other uses.

Fig. 11 shows one of these installations. Here a suction line runs along in front of the settling chambers of a smelter, over the doors. At each door is a Y connection. To these connections a flexible hose with suction nozzle can be attached wherever desired, and the settled material from within the chamber recovered.

Figs. 12 and 13 give us two views of an installation at a smelter used for similar purposes. Fig. 12 shows the main run for recovering dust from the flue and the

pipe lines to the tower in which are the collecting station and the bin. Fig. 13 shows the method of conveying the recovered material from the dust filters.

Figs. 14 and 15 show a photograph and the layout of an installation for unloading aluminum ore. In the photograph two men are seen unloading a car with two 3-in. flexible suction lines. The installation has a capacity of 20 tons per hour. This quantity, drawn out of the cars through two 3-in. hose, is elevated a little over 70 ft., with a horizontal conveying distance of about 50 ft. Each 3-in. hose pulls a little over 10 tons per hour; and, while one 4-in. hose would do this work, it is found easier to handle the two 3-in. hose than the one 4-in. hose. To make clear where a hose larger than 3 in. can be used to advantage, Fig. 16 is shown. Here a 4-in. hose is operating in the hold of a boat and the weight is so carried from above that the difficulty of manipulation is reduced. On the installation shown in this picture 30 tons of pebble phosphate per hour is discharged from the boat into cars on the wharf.

Many times objections have been raised to pneumatic conveying because of the high horsepower it requires when compared with such equipment as belt conveyors, screw conveyors and bucket elevators. It is not the writer's object even to suggest that pneumatic conveying will ever replace other conveying means where it is possible to operate these. However, there are to be found an unlimited number of places and conditions or applications where no other conveying system but the pneumatic can be used. For instance, one of these is shown in the headpiece. This photograph shows a $2\frac{1}{2}$-in. pipe line hanging on a wire rope and passing clear over a manufacturing plant of large proportions, said pipe line being 450 ft. long. Through this pipe line is conveyed night and day more than 3 tons of lime per hour which has to be passed on from one manufacturing process to another in a steady stream.

New problems are constantly coming up and are being solved; and the writer is of the firm opinion that, from month to month, considerable material can be added to the short outline given above. There is one more point to be mentioned before we close. Within the past 6 months a development has been made which opens the field of abrasive handling wide to the pneumatic conveyor, a thing which many past attempts have failed to accomplish. The reason why abrasive materials could not be handled before by pneumatic conveying was the excessive wear on the discharge locks rather than the wear on the pipe lines and hose. Six months ago, however, a new discharge lock was invented which

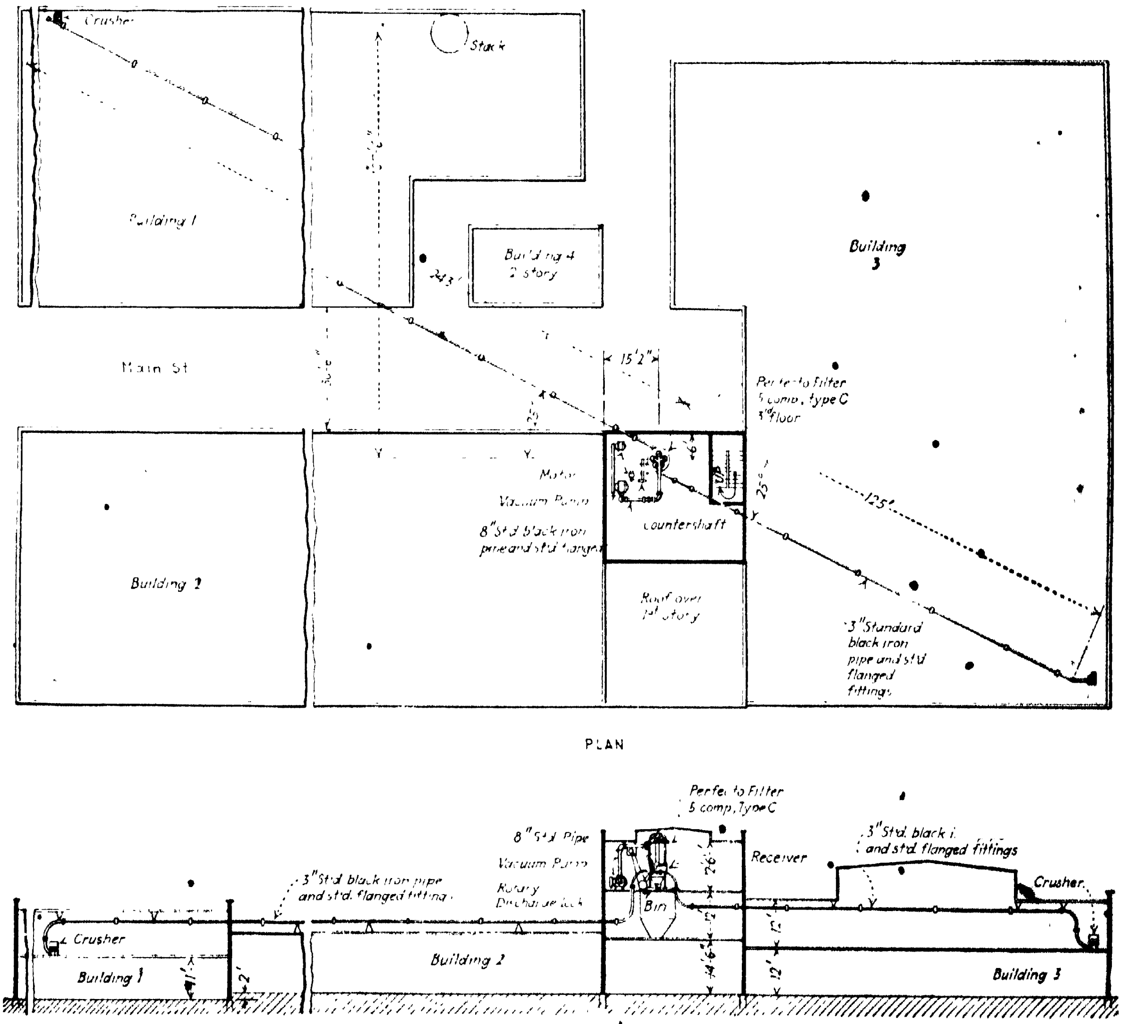

FIG. 9—LAYOUT OF LITHOPONE-HANDLING SYSTEM

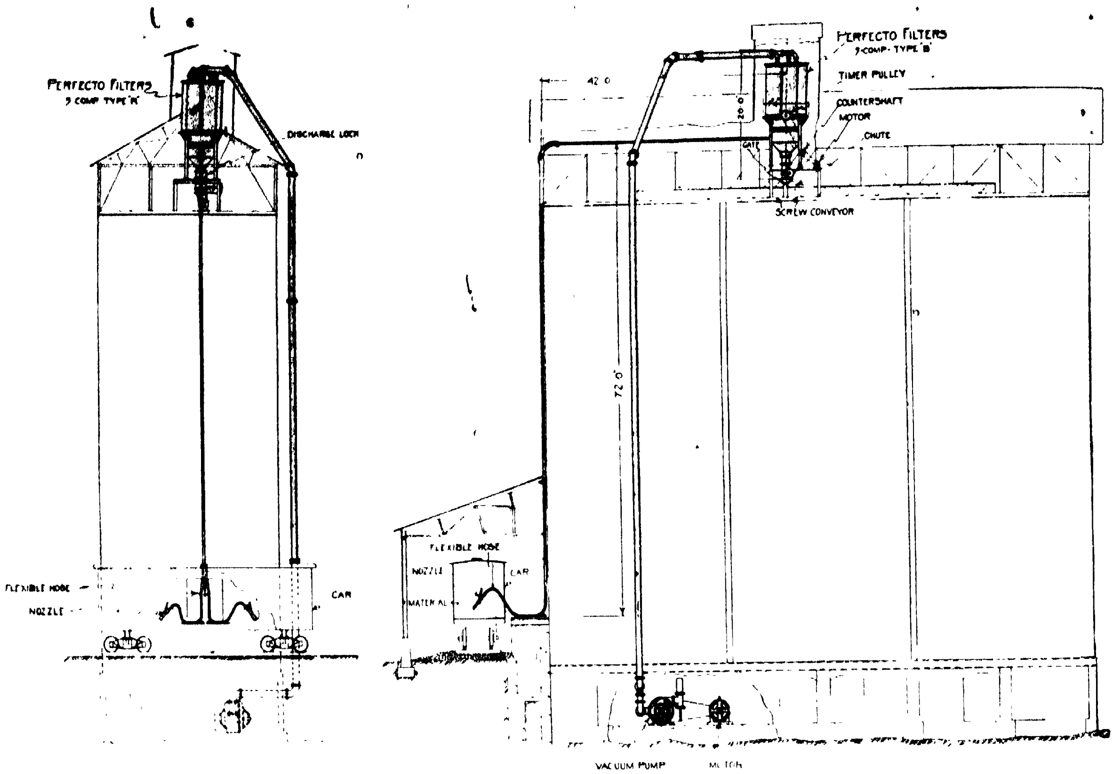

FIG. [illegible]. BAUXITE HANDLING SYSTEM LAYOUT

without any trace of wear is handling the most abrasive materials known. Fig. 17 shows this lock, which is called a three-valve discharge lock; while Fig 18 shows the rotary lock, which has been the standard unloading lock in the past and which is successfully handling all non-abrasive materials.

The installation shown in Figs. 14 and 15 has handled many hundred tons of bauxite concentrates, a material of an extremely abrasive nature, through this so-called three-valve lock; and, while the said material will wear out a screw conveyor in 3 weeks' time and a rotary discharge lock in less time than that, a three-valve lock has now been running for months on this material without any wear whatever. Great progress has also been made in the materials used for suction hose, and on this same installation the conveying hose and pipe lines show only insignificant wear; it, of course, being a fact that material at a high velocity travels at the center of the pipe lines and only strikes the pipe when the bends are sharp.

Chloridizing Silver Ores

Tests conducted at Western stations of the Bureau of Mines have shown that the roasting of silver minerals tends to produce metallic silver. Chloridizing roasting of silver minerals, therefore, is essentially a problem of chloridizing metalic silver and subsequent volatilization of silver chloride. In the furnace, conditions must be maintained that prevent the silver from being hydrolyzed and from reverting to the metallic state before passing from the ore as silver chloride.

Silver is not easily chloridized and volatilized, and has so far offered greater difficulty than any of the common metals. It seems extremely sensitive to atmospheric conditions in the furnace.

Silver minerals occur in many low-grade and complex ores of lead, zinc and copper, silver sometimes being of major importance, especially in economic value. A high percentage extraction is required to make any process for such ores commercially feasible.

In many ores the silver has minor value. When silver is present with rather high percentages of lead and copper, it may not seem economical to provide the conditions for making high extractions.

Salvages in the Oil Industry

A study is to be made by the Interior Department of salvages in the petroleum industry, with particular reference to production activities. The investigative work will be performed by C. P. Bowie, petroleum engineer, of the Bureau of Mines. Large sums of money are spent annually by oil companies in the purchase of new equipment such as casing, sucker rods, drilling and fishing tools, engines and the hundreds of other essentials that go to make up equipment for oil field work. This new material often replaces used or partly damaged equipment that many times is consigned to the scrap heap without proper thought as to the possibility of it being worked over or repaired and put back into service or made to serve some other useful purpose in the industry. Some of the larger companies have been doing a considerable amount of salvage work for a number of years and a few have departments whose particular object is the care and repair of salvaged materials. Careful study of the subject by the Bureau of Mines and dissemination of the information obtained should, it is believed, result in a very material saving to the many smaller oil-producing companies.

Production of Hydrogen By the Thermal Decomposition of Oil

Discussion of the Purity of the Gas Obtained in the Experimental Manufacture of Hydrogen for Government Air Services—Carbon Monoxide the Principal Impurity—Suggested Means for Eliminating It—Thermal Balance of Process

BY E. R. WEAVER,
Chemist, Bureau of Standards

IT IS the purpose of the present article to give only the more interesting data showing the variations in the composition of the gas obtained during the various runs of the plant. In Table I data are shown for each of the runs for which purity curves have been prepared. The table is self-explanatory with the exception of the temperature data, which represent temperatures observed shortly before the beginning of the corresponding runs.[1] A blank under generator-temperature indicates that no reliable temperature reading was obtained in the generator before the beginning of the run because of the presence of smoke. There can be no doubt that the maximum temperatures existing in the plant were higher than those observed; just how much higher it is difficult to estimate. The condition of the refractories in the vaporizer after the experiments indicated that the temperature at the bottom of the checker-brick column had been at least 100 deg. C. hotter than the maximum observed at the lowest sight cock.

PURITY OF HYDROGEN

Characteristic curves representing the variation of purity of the hydrogen produced during any run in which the rate of production remained approximately constant are shown in Figs. 4 and 5. All the purity curves obtained were similar in form to these; it can be readily seen that each of the more complex curves of Figs. 6 to 13 is composed of segments of the general shape of the curves in Figs. 4 and 5. Each such segment represents a period during which the conditions of production were not materially changed.

The three curves of Fig. 4 are typical of production at a low and fairly uniform rate. Although the maximum observed temperatures were rather high, especially in run 24, they were probably not well distributed and the poor yields and low purity are to be ascribed to temperatures too low to decompose methane successfully.

The various impurities are separated in Fig. 5, which represents a run made at high temperature with an oil feed of 1 gal. per minute. The impurities were determined in this case by volumetric analysis, and the irregularities were caused by the unavoidable variations in oil flow resulting from irregular air pressure in the supply tank. It is noteworthy that the carbon monoxide, always greatly in excess of the nitrogen, approaches a constant quantity, while the methane, which is negligible during the first half hour, increases rapidly toward the end of the run.

ELIMINATION OF METHANE

At the beginning of the investigation it was expected that the troublesome problem would be the elimination of methane. Such did not prove to be the case, however. The dominant impurity in all experiments was carbon monoxide. Nevertheless carbon monoxide is to be regarded as a more or less accidental impurity, the source and elimination of which will be discussed in the next section.

Figs. 6 and 7 show the results of a variation from the usual practice of vaporizing the oil on the checker

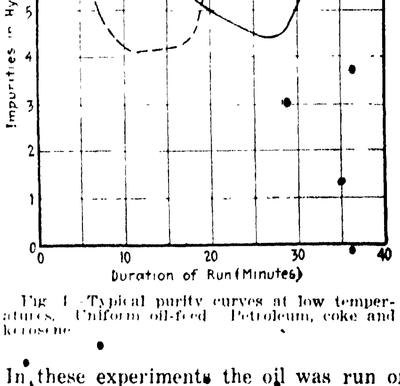

Fig. 4—Typical purity curves at low temperatures. Uniform oil-feed. Petroleum, coke and kerosene

brick. In these experiments the oil was run onto the coke and the vapors were passed from the generator through the checker-brick tower. It was hoped that this procedure would result in economy of time and fuel, because the carbon deposited in the coke bed could be burned more rapidly and efficiently than that deposited on the checkerwork.

During portions of both runs the oil vapor was passed directly from the top of the coke bed to the

---

*EDITOR'S NOTE: This is second in a series of three articles describing experiments carried out with the modified water-gas plant of the Gas Engineering Co., Trenton, N. J., for the purpose of obtaining a complete study of the process.

[1]Unless otherwise stated the oil was vaporized in the checker brick and passed through both the checker brick and the coke bed in all the experiments described.

checker-brick tower without passing through the body of the coke. This was done in order to determine the efficiency of the checker brick alone in producing hydrogen, with special reference to the possibility of dispensing with a coke fire and using an oil or gas fire as a source of heat. The results definitely prove that gas passed through the checker-brick tower alone contains several times as much methane as that passed through the hot coke. This was found to be the case in spite of the fact that the observed temperature of the checker brick was higher in run 26 than in any other experiment except runs 34 and 45.

No apparent advantage of any kind resulted from vaporization in the coke bed; and the latter was so clogged up by the deposited carbon that only short runs could be made. This factor more than offset any advantage which might have resulted from the more efficient utilization of the carbon produced during blasting.

The very poor results obtained when the checker brick

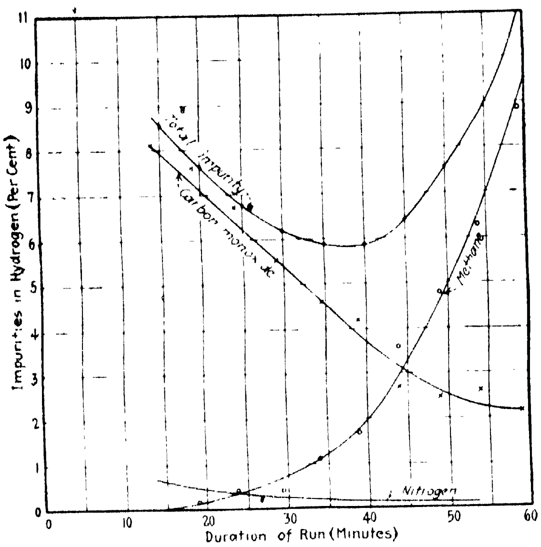

Fig. 5—Composition of gas produced in run 34 as determined by volumetric analysis

alone was used as a heating surface were probably due as much to the lower temperature of the brick as to the smaller surface of contact. The effect of temperature is well shown by comparison between runs 35 and 36 (Fig. 8). The difference in the results obtained is to be ascribed entirely to the formation of methane at the lower temperatures of run 36. A still more instructive comparison may be made between runs 41, 42, 43 and 45. (Figs. 9 and 13.) Runs 41 and 42 were purposely made at low temperatures in order to study the effect of temperature. In run 43 the temperature of the checkerwork was about 200 deg. higher, and the effect on yield and purity is at once apparent. In run 45 a further increase in the temperature of the checkerwork gave still better results, although the apparent temperature of the coke was less than that in run 43. This and other similar observations show that the temperature of the checker brick is a much more important factor than might be assumed from the fact that the final elimination of methane must be accomplished in the coke bed. Indeed checker-brick temperature appears to be quite as important as coke temperature. It is probable that most of the endothemic reaction takes place in the

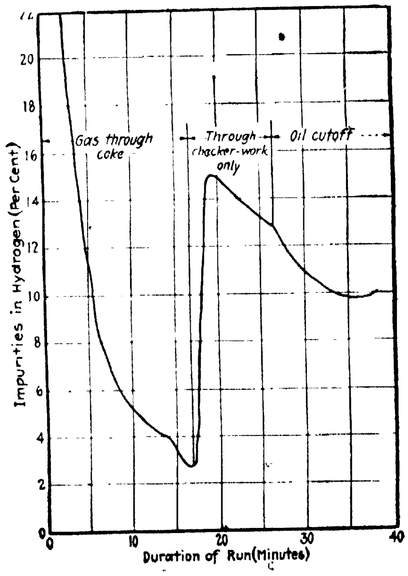

Fig. 7—Effect of passage through coke upon removal of impurities. Rate: 0.5 gal. oil per min.

checkerwork and that a relatively small decrease in efficiency there puts a much greater load on the coke. If, for example, 90 per cent of the endothermic reaction takes place in the checker brick, a decrease of 10 per cent in their efficiency would about double the amount of heat taken from the coke to complete the reaction. This relation is substantiated by the facts that the first hydrogen produced, even in the runs made at the lowest temperatures, was found to be nearly free from methane and that the initial temperature was observed to affect principally the amount of oil which can be used before an appreciable amount of methane appears.

The Source of Carbon Monoxide

The plant would have produced hydrogen of quite satisfactory purity from the start had it not been for the occurrence of considerable amounts of carbon monoxide. It is evident that any free oxygen in the system

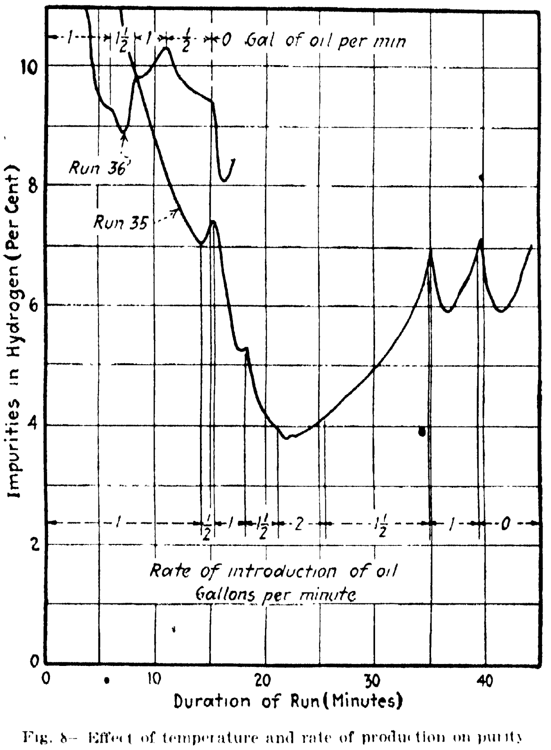

Fig. 8— Effect of temperature and rate of production on purity

or oxygen in any compound which can be reduced by hydrogen or carbon at temperatures up to 1,600 deg. C will appear in the gas as carbon monoxide. The sources of the oxygen were ultimately determined with some certainty to be: (1) water vapor from the Silocel lining of the generator, and (2) oxides of iron present in the machine.

The source of this principal impurity (carbon monoxide) in the hydrogen is of so much importance that the reasons for the conclusions given will be stated in detail.

The principal possible sources of oxygen appear to be as follows: (1) Air remaining from the blast or included in coke or linings. (2) Water or organic compounds containing oxygen in the oil. (3) Water or organic compounds containing oxygen in the coke. (4) Any materials, notably iron, or iron oxides, which remain in any heated portion of the system and can be oxidized during blasting and reduced by hydrogen or

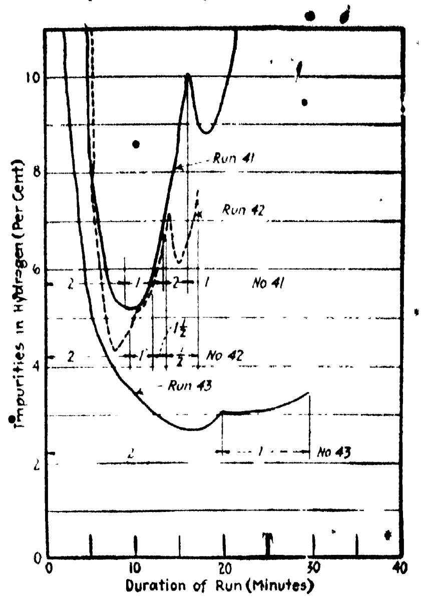

Fig 9—Effect of temperature on production.

carbon during hydrogen production. (5) Water from a leak in the water-cooled valve between generator and checker-brick tower. (6) Water from the linings of the generator.

If the oxygen had come from air, each volume of carbon monoxide would have been accompanied by approximately twice its volume of nitrogen. On the contrary, the amount of nitrogen found was always very small after the first minute or two of the run, seldom amounting to more than 10 per cent of the carbon monoxide in the samples taken for volumetric analysis.

The rate was computed at which carbon monoxide was being produced at the time each volumetric analysis was made. It was assumed that the nitrogen present was

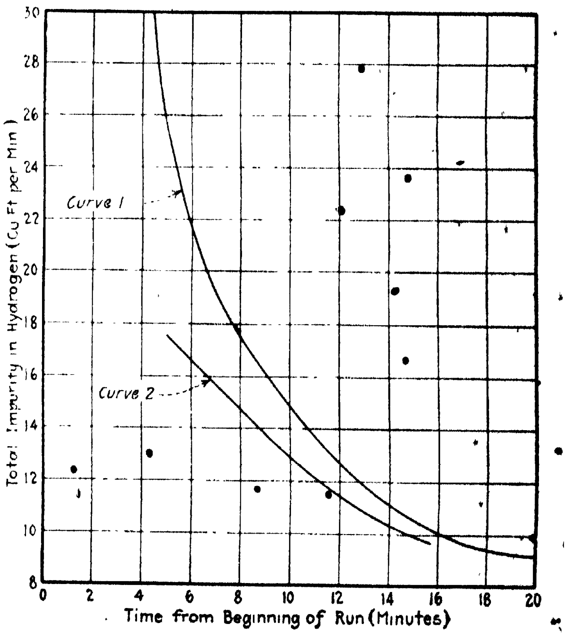

FIG. 10—TOTAL IMPURITY IN HYDROGEN

Curve 1—Graphic average of six runs at 2 gal. per minute.
Curve 2—Graphic average of six runs at 1 gal. per minute.

residual blast gas and that an amount of carbon monoxide equal to one-half the volume of nitrogen should be ascribed to the same source. Half the percentage of nitrogen was therefore subtracted from the percentage of carbon monoxide found by analysis, and the remainder was multiplied by the rate of hydrogen production. This gave the volume in cubic feet per minute of carbon monoxide produced, presumably from some source other than residual blast gas. The figures so obtained throw much more light on the question of the source of the carbon monoxide than do the analyses alone and will be frequently referred to.

Eliminating Oil and Coke

No considerable part of the oxygen could have come from the oil, since the amount of carbon monoxide produced per unit time was almost, if not quite, independent of the rate at which the oil was introduced. (See Fig 10.) Consequently, a sudden increase in the rate of hydrogen production was always accompanied by a corresponding decrease in the percentage of carbon monoxide in the gas. A change in rate of production was also, of course, accompanied by a change in the percentage of methane present, the effects upon the concentration of methane and carbon monoxide being in opposite directions. Consequently, an increase in rate of production near the beginning of a run, when carbon monoxide was the dominant impurity, always resulted in an increase of purity of the hydrogen; near the end of a run, when methane was in excess, a change of rate had the opposite effect upon the purity of the hydrogen; and at an intermediate stage of production the effects upon carbon monoxide and methane balance each other and a change of rate has no noticeable effect upon the percentage of impurity present. These effects are clearly shown by all the later runs, notably Nos. 35 and 38, Figs. 8 and 11.

That the oxygen did not come from the oil is also indicated by the fact that the amount of carbon monoxide produced was the same whether kerosene or fuel oil was used. The amount of carbon monoxide observed in some of the runs would have required as much as 12 to 15 per cent of any oxygen-containing organic compound; the occurrence of such a compound in such amounts in each of two refined petroleum oils is in itself so improbable as to eliminate the oil from further consideration as a source of oxygen. Water itself in any such quantity must have occurred as a visible emulsion.

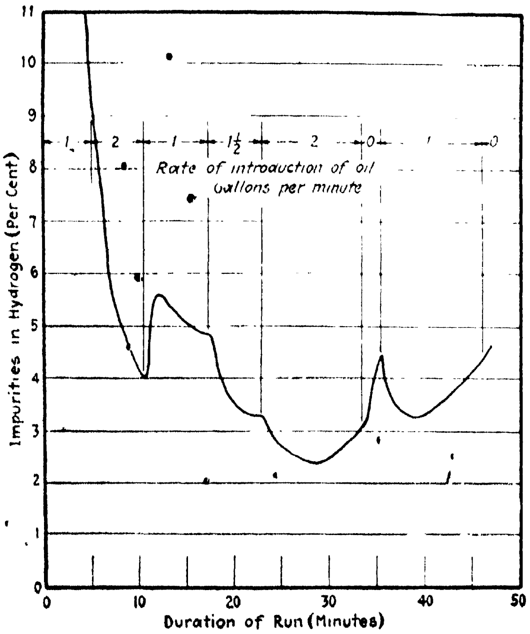

Fig. 11—Effect of rate of production on purity at different stages (run 38).

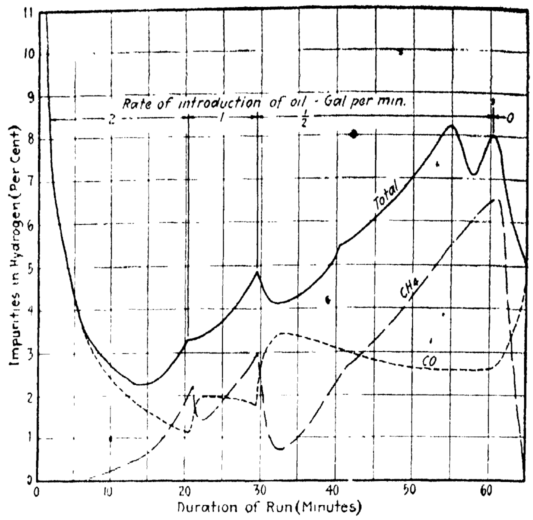

Fig. 12—Effect of rate of production on purity at different stages (run 11).

The coke probably did contain enough water at all times to drive out included air and fill the interstices of the solid with steam, but water or any organic compound of oxygen would have reacted with the carbon to form carbon monoxide at temperatures far below those actually employed, and all but a small part of the gas would have escaped during blasting. During one period for which computations were made, the carbon monoxide produced during the runs, if confined in the total volume occupied by the loosely piled coke, would have exerted, at the operating temperature, a pressure of at least 300 atmospheres.

The possibility of water leaking into the generator was one of the first considered, but there was no evidence of such a leak at the only point at which it could have occurred.

The Remaining Sources of Hydrogen

Water from the linings, and iron oxide or other materials which can be alternately reduced and oxidized, alone remain as sources of oxygen. There is abundant evidence that each of these played some part in the actual formation of carbon monoxide.

The reactions involved are very simple Water vapor will react with carbon to produce carbon monoxide and hydrogen, while iron oxide will react with hydrogen to produce water, which will immediately give carbon monoxide. The reduced iron remains in the generator until the next blast, when it is again oxidized by air or even by carbon dioxide and so carries oxygen over into the next run.

A considerable part of the impurity can unquestionably be ascribed to water in the linings of the generator and checker-brick tower, which consisted of firebrick backed by Silocel powder. The latter material was packed into position in the form of a paste, and the water in the paste could escape only by evaporation. It may even have been partly renewed in some cases

where wet coke was put into the machine, and the steam produced may have entered the colder parts of the lining and there condensed.

The source of the reactive iron is not so easily ascertained. Some parts of the shell and connections were exposed to relatively high temperatures, especially valve stems and the metal not covered by the lining around the secondary air inlets, the charging and stack valves, and the sight holes. Some iron, no doubt, came from scale from various metal parts during erection and use, some from pyrometer tubes, some from lintels and old grate bars,[2] some from ash of the fuel, and some from iron oxide in the refractories. Some iron rust may even have been carried in suspension by the oil from the storage tank and connections.

The iron oxide in the refractories was probably the greatest single source of oxygen. The dust produced by rubbing together two of the checker brick took up 0.1 per cent of its weight of oxygen when heated to redness in an oxidizing atmosphere and lost the same amount in an atmosphere of hydrogen. This test was repeated two or three times consistently. The brick were porous enough to account for an enormous effective surface exposed to the action of the gases.

The Case Against the Lining

The following facts point to water from the lining as a source of a considerable part, at least, of the carbon monoxide:

(1) There is a tendency for the amount of carbon monoxide produced per minute to increase during the period of experimentation. This, no doubt, corresponds to a drying out of the Silocel.

(2) No direct connection can be traced between the rate of carbon monoxide formation in the different runs and the temperature at the beginning of the run, but there was a decided tendency for the carbon monoxide production to increase during the first two or three runs following a shut-down. This was to be expected, since the rate of escape of water vapor from the wet outer layer of the lining was no doubt proportional to the amount of heat conducted through firebrick and dry inner Silocel.

(3) That some water still remained to be evaporated was proved when the lining of the generator was torn down after the experiments. A sample of the Silocel from near the top of the generator was found still to contain over 5 per cent of water, enough to condense in the top of a test tube when a few grams of the powder was heated in the bottom.

(4) At various times, but especially when running oil directly onto the coke, the generator became clogged with carbon to such an extent that the pressure of hydrogen would force open the stack valve. Every time this occurred a sharp increase of carbon monoxide was shown just before the valve opened. It even became possible to predict with some accuracy when the valve would open by watching the purity recorder. The sudden increase of impurity was, no doubt, caused by the hydrogen being forced through the porous lining, carrying with it an unusual amount of steam. This explanation was verified by broad streaks of lampblack found in the Silocel when the lining of the generator was torn out.

[2]The lintels which support the lining above the ash pit and fire doors were found to be fused about three-fourths of the way through the lining after the experiments.

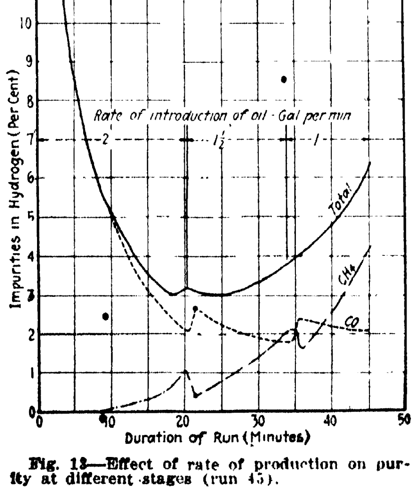

Fig. 12—Effect of rate of production on purity at different stages (run 45).

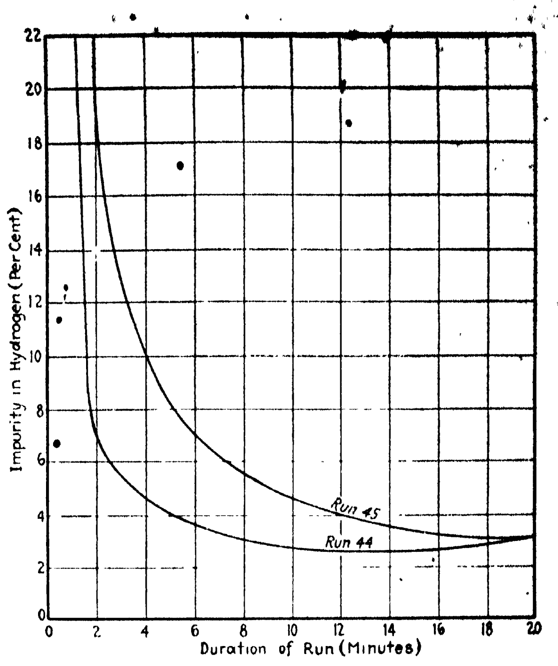

Fig. 11—First 20 min of runs 44 and 45, showing effect of preliminary reduction on purity of hydrogen. 2 gal. of oil introduced into machine 10 min before beginning run 44

The Case Against the Iron Oxide

That iron oxide caused the formation of a large quantity of carbon monoxide is indicated by the following facts:

(1) It is impossible to account for the variation in the rate of formation of carbon monoxide during a single run by assuming that it all comes from water in the lining. The lag involved in the conduction of heat through firebrick and dry Silocel is such that no rapid variation in the rate of vaporization of the water in the wet Silocel can be credited. Even if there were no lag, but the amount of heat transmitted through the lining was always exactly proportional to the difference in temperature, no variation greater than about 20 per cent could be accounted for in the rate of formation of carbon monoxide between the beginning and the end of the run; while the observed variation usually amounted to several hundred per cent.

(2) The amount of carbon monoxide formed was

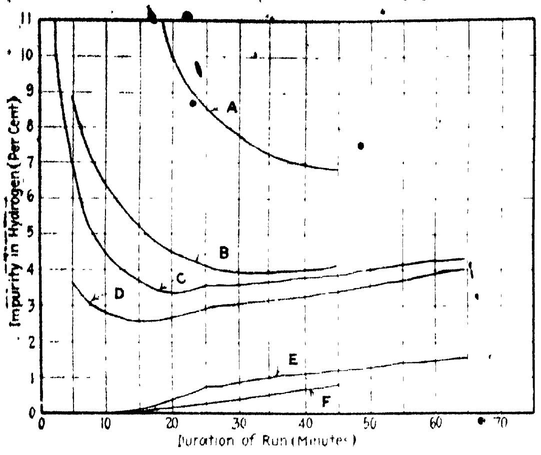

FIG. 15—COMPOSITION OF HYDROGEN IN HOLDER FROM RUNS 44 AND 45

Curve *A*—Run 45 Total impurity, all gas saved
Curve *B*—Run 45 Total impurity, gas wasted during first 5 min.

greatly diminished by introducing a little oil several minutes before beginning to run and permitting it largely to reduce the iron oxide present. This is clearly shown by a comparison between runs 44 and 45, of which the complete purity curves are given in Figs. 12 and 13. These runs were made under conditions very similar in all respects except that in the case of run 44 about 2 gal. of oil was introduced into the generator 10 minutes before beginning continuous operation. Fig. 14 shows the first portion of the same purity curves on an enlarged time scale and a reduced purity scale. These curves are continued to represent the course of the runs only so long as oil was introduced at the initial rate. The practical effect of the preliminary reduction is strikingly illustrated in Fig. 15, which shows the percentage of impurity in all the gas delivered to the holder in the case of the two runs. In these and all other runs an amount of hydrogen equal to at least the volume of the shells was wasted through

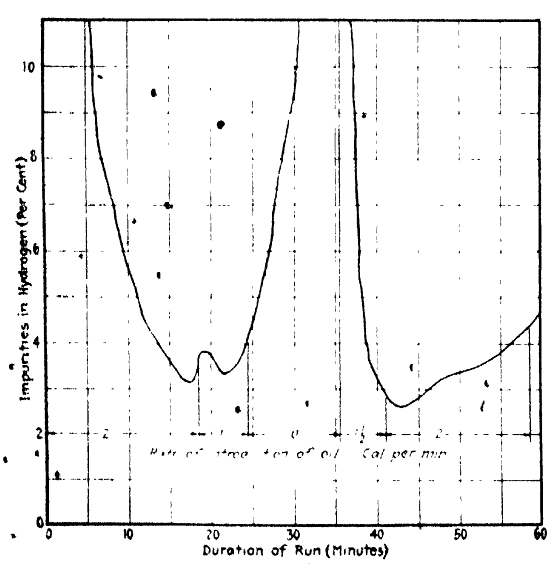

Fig. 16—Showing improvement in purity of hydrogen following a temporary shut-down (run 37).

a purge valve before the gas was turned through the meter and the figures represent only the gas actually metered. It is apparent that the use of 10 gal. of oil during a period of 5 minutes is less effective in eliminating impurities than is the use of 2 gal. 10 minutes before the run.

Fig. 16 also illustrates in a striking manner the result of a long period of reduction upon the impurities in the gas. In this case the introduction of oil was interrupted for 11 minutes after a 25-minute run. When production was again started, gas of higher purity was produced in greater quantity than during the first portion of the run in spite of the heat lost during 25 minutes of operation and 10 minutes of idleness.

(3) The smallest rate of production of impurities occurring in any of the experiments was in run 26 (Fig. 6). In this run the oil was vaporized in the upper part of the coke bed, and during the first 7 minutes was passed through the checker-brick tower only. When the gas was then directed through the coke, the remarkably low rate of 1.2 cu.ft. of impurity per minute was observed both from the record of the automatic recorder

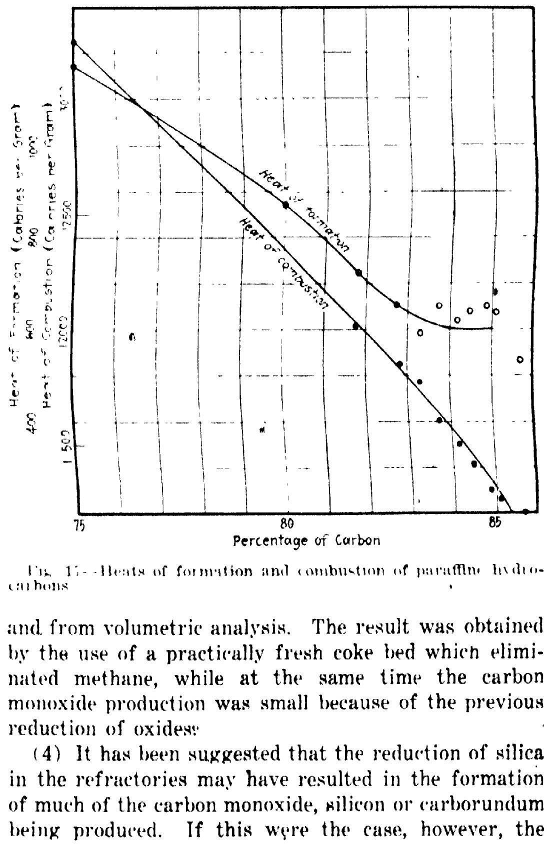

Fig. 17—Heats of formation and combustion of paraffin hydrocarbons

and from volumetric analysis. The result was obtained by the use of a practically fresh coke bed which eliminated methane, while at the same time the carbon monoxide production was small because of the previous reduction of oxides.

(4) It has been suggested that the reduction of silica in the refractories may have resulted in the formation of much of the carbon monoxide, silicon or carborundum being produced. If this were the case, however, the rate of formation of the gas in the presence of a large excess of the solid should be a rapidly changing function of the temperature. No increase in the rate of formation with increase of temperature was noted, however. On the contrary, the results indicate the reverse, but this apparent reversal is no doubt due to the fact that the highest temperatures were employed after the lining was pretty well dried out. The independence of temperature shown by the rate of formation of carbon monoxide and the rapid decline of the rate during a run can be explained only by a chemical reaction which would take place at a much lower temperature

but which is limited by the small amount of the reacting substance present. The evidence again points to iron oxide, although it is possible that some other oxide present in small quantity may have had some part.

Thermal Balance of the Process

The heats of combustion of various saturated hydrocarbons of the paraffine series, taken from the Landolt-Börnstein Tables, are shown in Fig. 17, together with their heats of formation obtained by subtracting the observed heat of combustion from the heat of combustion of the component carbon and hydrogen. Since the observations on heat of combustion were mostly made with bomb calorimeters, it is evident that the "heat of formation" here given includes the heat of vaporization and represents the total amount of heat which must be supplied by the checker brick and coke to vaporize and decompose the oil.

All of the paraffine hydrocarbons that are liquid at ordinary temperatures contain between 88.33 and 85.75 per cent of carbon. It is apparent, therefore, that it makes little difference what oil is used, either as to yield of hydrogen, fuel value of the deposited carbon, or heat required to decompose the oil. Provided the checker brick is sufficiently hot to vaporize the heavier oil, practically the same results should be secured from the use of the same weight of a heavy lubricating oil, or even solid paraffine, as from gasoline or kerosene.

It is assumed, for the purpose of drawing an approximate thermal balance, that an oil of specific gravity, 0.80, containing 85 per cent carbon, is used under the operating conditions of run 45, which are believed to represent about the most favorable operating conditions for this plant. (The question of preliminary reduction of the iron oxide in order to avoid the formation of carbon monoxide has practically nothing to do with the thermal balance.) It is also assumed that 75 per cent of the carbon of the oil was deposited on the checker brick and that this was burned to CO only, the carbon in the generator being all burned to CO_2.

Table II then represents roughly the thermal balance indicated by the observations made on run 45, in which 13,680 cu.ft. of hydrogen was produced.

TABLE II APPROXIMATE THERMAL BALANCE OF EXPERIMENTAL PLANT

	Total Kg Cal	Btu Per Cu Ft of Hydrogen
Potential heat of fuels used		
247 kg. oil	2,790,000	718
159 kg. coke	1,280,000	329
Total fuel used	4,070,000	1,046
Heat accounted for		
Potential heat of 37 kg hydrogen	1,260,000	324
Heat required to vaporize and decompose 247 kg oil	160,000	41
Sensible heat in 37 kg. hydrogen at 1,200 deg C	160,000	41
Sensible heat in products of combustion of carbon at 1,000 deg. C.	885,000	228
Potential heat of 370 kg CO	900,000	231
Miscellaneous losses, including radiation, carbon suspended in hydrogen, purges and leakage	705,000	181
Total	4,070,000	1,046

The figures in Table II are very rough approximations only. In particular the temperatures at which hydrogen and blast gas leave the plant are mere estimates. The balance is sufficiently near the truth, however, to show the very poor thermal efficiency of the process and to indicate the direction in which to work for improvement.

The concluding article in this series, which will discuss the arrangement and operation of the plant for thermal efficiency, will be published in a subsequent issue.

Plan for Critical Tables of Constants

The International Critical Tables of Physical and Chemical Constants have been outlined to some extent by the editorial board. The very general interest aroused by this work is due to the wide application of constants involved, bearing as they do upon a very broad range of industries. The scope of the tables is indicated by the following topics: Chemical kinetics, kinetics of physical processes, diffusion, molecular kinetics, chemical equilibrium, pressure-volume-temperature relations in homogeneous systems (does not include H_2O, CO_2, SO_2, Na., Hg, air, N, H, Si), phase relations in heterogeneous systems, volume change accompanying change in phase where directly determined, properties of surfaces, electrochemistry, thermochemistry, photochemistry, mechanics, sound, heat, radiometry (including spectrophotometry, electricity, magnetism, electronics, ionization of gases, X-rays, miscellaneous tables of useful information, certain biological data, assembled properties of selected materials, conversion tables, tables of units and standards, standardization tables, and computational tables.

Among the industrial materials on which data are to be included are the following: Minerals; alloys, amalgams and commercial metals; abrasives, ceramic cements and cementing materials, exclusive of refractory cements; clays; heavy clay products; natural building materials of mineral origin; refractory materials, including refractory cements; white wares, including laboratory porcelain, electrical porcelain, etc.; commercial glasses; vitreous enamels; thermal insulating materials for high temperature; low-temperature insulating materials; woods; rubber and artificial plastics; carbon for electrical purposes; mica; transformer oils and other liquid electrical insulating materials; asphalts, bitumens, tars, pitches, mineral waxes and creosotes; lubricants; liquid fuels; solid fuels; animal and vegetable oils, fats and waxes, including hydrogenated oils but excluding essential oils and processed oils; essential oils; natural and artificial resins, gums and balsams; odoriferous materials; solid secretions of animal origin, such as bone, ivory, shell, horn, coral, etc., and some artificial substitutes; skins, leather and leather substitutes; cat gut and allied substances; textile fibers, including animal, vegetable, mineral and artificial; sponges, mosses, sea grasses, etc.; explosives; tannins; dyes, pigments and coloring materials; sweetening agents; foodstuffs; adhesives; paper; paints, varnishes, airplane dopes and raw materials; refrigerating brines; nitrating acids; molding sands.

Jersey Sand as a Water Softener

Green sand marl is suitable for direct use as a water-softening agent, says the geology division of the Department of Conservation of Development of the State of New Jersey. Large quantities of this green sand occur in southern Jersey. The state bulletin says:

"After certain preliminary treatment, which charges it with exchangeable sodium, the marl is placed in the water softener and the water allowed to flow through it in a manner somewhat resembling the ordinary filter. The exchangeable sodium of the treated marl combines with the calcium and magnesium, the presence of which causes the hard water. The marl in turn gives up a proportionate quantity of sodium to the water. To restore it to complete efficiency it is necessary only to pass a solution of brine through the apparatus."

Principles of Chemical Engineering*

A Symposium Review of an Outstanding Work on Chemical Engineering of Value Alike to the Student in College and to the Seasoned Engineer

The Book: Its Significance

The Older Engineer Will Welcome This Volume as Enthusiastically as the Student

BY HENRY HOWARD
President, American Institute of Chemical Engineers

THIS BOOK will be found useful to every chemical engineer as a part of his working library. When Davis in 1901 brought out his "Hand Book of Chemical Engineering" in England, he was striking into what was then an almost untouched field. I do not know of anything that will impress one more as to the progress made in the "science" of chemical engineering than a comparison of these two books.

Another point that cannot fail to impress anyone who is not familiar with chemical engineering is the wide range of technical knowledge that is required by the well-trained chemical engineer of today. The authors should be particularly commended for the way in which they present the fundamental theoretical conceptions, both physical and chemical, which underlie or at least give useful explanations of the various subjects covered. The chapter on combustion deserves special mention, because of the suggestive way in which the subject is discussed.

The book is particularly valuable to older engineers who have not had the benefit of modern systems of instruction, in that the mathematical and chemical calculations are so carefully and logically developed that the older engineer will find their study most stimulating.

It is to be hoped that the prevent volume is merely the forerunner of amplified editions that the same authors will bring out from time to time, as was the habit of Dr. George Lunge in his various editions of "Sulphuric Acid and Alkali," which have performed such a wonderful service for the chemical industry of the world.

This criticism would not be complete without pointing out what seem to me to be shortcomings in the book. The space given to heating by powdered fuel and oil firing seems inadequate. Both of these methods are being widely adopted in chemical processes, especially where uniform conditions of temperature and oxidizing or reducing atmospheres are required. Inexpensive and satisfactory powdered coal equipment that requires no preliminary coal drier and which presents no explosion hazard is now available—for instance, the Aero pulverizer. The chapter on crushing and grinding gives some excellent information and data, but principally describes apparatus useful for very large-scale operations that are more commonly met with in mining.

Many more criticisms could be made, but the fact remains that the book presents much new material and is a very real contribution to the literature on this subject. It should be in every chemical engineer's library.

*"Principles of Chemical Engineering," by William H. Walker, Warren K. Lewis and William H. McAdams. New York: McGraw-Hill Book Co., 1923. 637 pages, $5 net.

Industrial Stoichiometry

A Difficult But Necessary Subject for the Chemical Engineer Presented in a Common-Sense, Usable Way

BY JOHN MORRIS WEISS
Consulting Chemical Engineer, New York City

THE chapter on the elements of industrial stoichiometry might well have been entitled the elements of mathematical common-sense. The author has taken the attitude that figures should be our servant and not a bogy. The simplification of the methods of calculation from one system of units to another by placing all figures on a molecular or atomic basis, though not new, is presented in a very clear and thorough fashion.

This chapter also brings to the attention of the reader a few of the more useful approximations of physical chemistry such as Trouton's formula for latent heats of vaporization. These are indeed extremely useful and will often serve for the sufficiently approximate solution of a problem in cases where exact data are unavailable in the literature and where the determination of the exact data would entail a burden out of proportion to the resulting extra exactitude of results.

The section entitled "Efficiency" would, in the writer's opinion, be advantageously susceptible of enlargement. There are many types of industrial processes in which the way the yield figures are stated is often puzzling and not co-ordinated. In the single example given, the author should have been more explicit in his definition of "recoverable salt." If he meant recoverable in the same state of purity as the original crude salt, his mathematical interpretation is the correct one. Some factor, however, should be introduced to distinguish two processes which by the author's method might show the same mathematical efficiency and yet the output *in one cycle* per unit of crude might make one process immeasurably more efficient commercially than the other.

The sections on "Choice of Data" and "Sampling" are to be highly commended. There is no doubt that in many instances chemists and engineers collect many useless data at great expense while neglecting obvious data readily obtained with little or no effort. In the discussion of the boiler tests and in the sample calculations given it would seem rather dangerous to base extensive calculations on the results ordinarily obtained with an Orsat gas apparatus, and it would seem desirable, where such calculations are to be made, to suggest the use of a more accurate analytical method than the one used. The section on "Sampling" is very pertinent and too much emphasis cannot be placed on its importance. The writer feels that similar emphasis might well have

been placed on the selection of accurate analytical methods and care in the application of these methods to the materials of the process.

On the whole, the chapter is stimulating and suggestive and represents a real contribution to chemical engineering thought. The principles are sound and, I believe, most useful to the practical experienced man. In fact, I feel that in the hands of the inexperienced the chapter may prove a dangerous tool. In Illustration I, if there is soot from either incomplete combustion or a leakage of air in the setting of the boiler, the calculations of the various results might be seriously in error. No doubt such matters are considered in later chapters, which at the time of this review I have not seen.

To the seasoned engineer, however, such matters are obvious, and to him the work is extremely useful, replete as it is with helpful suggestion and simplification of the mathematical problems with which we all have to deal in our daily work.

The Physical Basis for Chemical Engineering

The Chapters on Fluid Films, Flow of Fluids and Flow of Heat Form an Engineering Background to the More Restricted Consideration of Special Equipment

By George L. Mitchill, M.E.
New York City

Valuable technical books are being published continually; but it is only at rare intervals that a book is issued of such outstanding interest that it marks an epoch for its field. Such a book, to our mind, is "Principles of Chemical Engineering," by Professors Walker, Lewis and McAdams of M.I.T. It is the first successful attempt to place the study of chemical engineering on a basis of rational fundamentals. As a contribution to the text-book literature of this subject it marks the beginning of a new attitude toward chemical engineering.

THAT part of this work dealing with "Fluid Films" is descriptive, merely defining and declaring the existence of such films, and explaining their general effect on the flow of liquids and the transfer of heat. Incidentally the existence of such films is shown to explain the difficulty with which liquids commonly dissolve or absorb minute particles suspended in the air or other gas with which they are in contact. A clear conception of the nature of such films and their bearing on engineering problems can be drawn from this part of the work.

The treatment of the "Flow of Fluids" thoroughly covers the broad field indicated by the title. Introducing the conception of potential pressure and velocity head early, the authors show the manner in which these are connected with the action of various types of devices used for measuring pressure and flow. After a discussion of the mechanism of flow through conduits, these devices are considered with reference to the effect of changes in volume, temperature, viscosity, etc., on the indications read on various types and the energy loss incidental to their use.

In that part of the work devoted to the flow of heat, the authors define and thoroughly consider the mechanisms of conduction, convection and radiation of heat. Proper consideration is given to the effect of various complicating factors which so often intrude themselves in practice.

In scope, these chapters are not as broad as the titles, though they are in exact conformity with the title of the book. True engineering is the application of these "principles."

The scope and treatment are as applicable to mechanical or any other form of engineering as they are to chemical engineering, which is as it should be. The chemical engineer is expected to apply the principles of the science of chemistry; but to produce commercially successful results he must have recourse to the application of the science of mechanisms. He would hardly be expected to design heavy machines; but he would surely be expected to outline the piping system he required to handle his liquids or gases—that seems such a simple matter. However, the general design of an economical piping layout involves many factors and considerations quite foreign to chemistry, but these will also be controlled to a considerable extent by the chemical engineering. For example, piping a liquid at a certain temperature may so decrease its viscosity as to result in a distinct saving in power, offset perhaps by the cost of insulating the piping. There may be a technical as well as an economical limit to this temperature. The chemical engineer must possess the knowledge to control both factors to be truly successful.

Perhaps the above is a poor example, but it illustrates the point. A text book of chemical engineering should include the basic principles of mechanical engineering, with particular stress on such matters as flow of liquids and heat. This one does.

As to general scope and viewpoint, then, this book is what it sets out to be. Now, is it a good engineering textbook as to the line drawn where principles end and specific commercial methods begin? It is. It is no condensed catalog of flow meters, oil heaters, or pyrometers, notwithstanding that the principles of these and many other devices are considered.

Does it lean too far the other way? Does it dwell on the discovery of this or that natural law or detail of experimental methods by which physical constants were discovered? It does not. The laws are stated and formulated, the constants tabulated, and then the application is shown— which in the writer's opinion constitutes engineering.

Good engineering must be not only sound in its application of natural laws and physical constants, but must be reasonable. The formulas mathematically derived therefrom should be simplified by appropriate assumptions and approximations consistent with the degree of reliability necessary to commercial results. This book does so. The simplifications generally permissible or permissible in special cases are quite usually indicated.

Much more might be said along these lines, in general quite favorable to the book, as judged from the part here reviewed. But there is a different point to be considered. A text for students should be readable and interesting, consistent with brevity and complete mathematical

demonstration, if it is to be of much use in connection with American methods of teaching. For my part, I found this text interesting reading. References are well placed and easily found and the general arrangement is such as to avoid defeating the end of the work by breaking the student's train of thought.

All the above might be said without justifying the existence of the book as a text, especially if it is new. There are many such already. One might collect matter from this one and that one, arrange it differently perhaps, and evolve a new book satisfying most of the requirements of an engineering text. But such a book might not be at all justified. A new book should contain something new—not only as to arrangement but if possible as to material and information. I am impressed with the references to up-to-date literature and experiments and also such matters as the close consideration of fluid films in most problems in both flow of fluids and of heat. Also the discarding of empirical friction coefficients and the general solution of flow of liquid problems by a formula and curves which take into consideration all the many factors involved.

The authors should polish up some of their text, slightly change the form of a few formulas, stress some points differently and make a few typographical corrections. But I feel that the general arrangement and mode of presentation will stand the test.

The Art of Drying

A Subject Which Has Labored Under a Burden of Empiricism Is Brought by the Authors to the Dignity of a Science

By A. W. Lissauer
W. L. Fleisher & Co., Engineers, New York City

THE art of drying deserves recognition as a science, and a helping hand to aid its ascent from among the rule-of-thumb trades to its rightful place with others deemed worthy of academic study. It is not difficult to see why this has been a subject relegated to the tender mercies of the plant mechanic for solution; the removal of water by evaporation seems so simple—only a few trays, a box, some pipe coils and perhaps a fan, and presto! another drier is created. And at the same time is created one of two mental attitudes: if the mechanic by chance happens to guess right, "drying problems are too simple to bother with scientifically"; but if he happens to guess wrong, some one else, perhaps the office boy, is given an opportunity to outguess Nature! In either event, no attempt is made to discover the whys and wherefores, no data are collected, no progress is made. It is true that manufacturers of drying equipment have made valiant attempts to find out why their apparatus functions—or otherwise; but such data, all too often unfortunately, are crystallized into a "one grain per cubic foot absorption" philosopher's stone, or a collection of "designs of driers that have worked."

It is a great step forward in the right direction, then, to have the authors of this work on chemical engineering devote so large a part of it to this subject. One cannot help being impressed with the fact that they, among the leaders in their field, are convinced that sure, efficient and economical drying is one of the essential processes in modern industrial engineering. So also the reader is convinced of the inclusive background of properly and scientifically carried out experimental work, without which the most erudite analysis is merely scientific guesswork.

Everyone will acknowledge that the drying field is large; perhaps two-thirds of our industries require or use some type of such apparatus. It is, therefore, unfortunate that only a chapter has been allotted to contain within its bounds all that has been deemed worthy. Such concentration inevitably means generalization, with consequent danger of misleading the inexperienced who are unable to guide themselves concretely with only the general direction pointed out. The interest which this book will create will, it is hoped, encourage the authors to enlarge on the subject and to include a résumé of their experimental work, the results of which, as is so clearly pointed out, are so necessary for the solution of specific problems.

This chapter on drying is welcomed as an earnest effort to place the subject in its deserved place among the other chemical engineering processes; that those who refer to the book will be convinced that this has been accomplished is a foregone conclusion.

Evaporation and Evaporators

The Mechanism of Vaporization and Its Application in Various Processes of Evaporation and Types of Equipment

By E. J. Winter
Consulting Chemical Engineer, New York City

PAGES 375 to 435 deal with evaporation and evaporators. The mechanism of vaporization is explained, the factors controlling it are enumerated; and all evaporation processes are subdivided into four classes, according to heat supply and vapor removal. Steam-heated evaporators have been given the prominence they deserve. The true importance of vacuum and multiple effect evaporators is explained, and the various considerations which govern proper design are carefully evolved.

The evaporators themselves are subdivided into eight groups, according to design and method of operation. Some of these groups are never met with in practice, although they are of real theoretical interest.

The authors discourage the use of exhaust steam, basing their conclusions on prime movers of the highest class. Nothing is said about the auxiliaries. This question must be decided, in each case, by a heat balance of the entire plant, and not by a general rule. Where exhaust steam is used for evaporation and the feed water enters the boilers cold, the use of exhaust steam is very costly.

The usual difficulties encountered during operation are taken up one by one and suggestions are made, in each case, for the diagnosis of the trouble and the remedy. The method of calculation for evaporator design is very carefully set forth, and two examples have been solved. The equations for multiple effect evaporation have been included, but in the examples shown the "trial and error" method is used, as is always done in practice.

Basic Principles of Distillation

The Separation of Liquids From Liquids Placed on a Rational Basis and Illustrated by Examples From Practice

BY E. J. WINTER
Consulting Chemical Engineer, New York City

THE concluding pages of the book are devoted to a careful and authoritative exposition of the various distillation processes. The underlying principles in the separation of immiscible, partly miscible, and mutually soluble liquids are explained; the limitations of Râoult's and Henry's laws are shown; and the correct method of procedure is deduced and applied in several examples. The minimum reflux and the effect of various reflux ratios have been determined by calculation, and are shown graphically; and the number of plates required deduced therefrom.

On page 602 a novel and very ingenious method is offered for calculating the point at which the feed should enter the column. It is based on equal "enrichment rates" of the plates, keeping the rate of rectification constant throughout the column.

The authors remark: "It would seem that in commercial practice the feed is often introduced too high up the column." In a number of cases this is merely apparent and well justified. Sorel and Mariller tested a mixture of pure ethyl alcohol and pure water, and the authors based their calculations on these results. The distiller's high-wines, however, contain a number of troublesome compounds, among others the fusel oils. These are high boiling, very sparingly miscible in water, but completely soluble in ethyl alcohol. The "exhausting" plates of the rectifying column—i.e., those under the feed plate—are poor in alcohol; fusel oil forms constant boiling mixtures with water, evaporating at a lower temperature than ethyl alcohol. In other words, the water in the immiscible mixture evaporates before the alcohol, and it becomes impossible to exhaust the waste on the number of exhaust plates calculated by the authors.

The two expressions for the free energy of separation of liquid mixtures are no better than the assumptions they were based upon, but the conclusions drawn therefrom are undoubtedly true. Compared with the minimum work of separation, distillation-rectification is a very inefficient process.

Usually the chemical engineer has no other means at his disposal for the separation of liquid mixture. Occasionally, however, other (chemical) means are available as well; and the surprising inefficiency of the method becomes evident by comparison. This in nowise detracts from the basic importance of distillation.

Gas Producers—Their Design and Operation

The Industrial Use of Producer Gas Is Increasing and Its Generation Is of Much Importance to the Engineer

BY G. L. MONTGOMERY
Assistant Editor, *Chem. & Met.*

THE use of various types of fuel gas is of ever-increasing importance, as the authors have pointed out in earlier chapters. As this use increases, the equipment for manufacturing the gas must also increase in importance. Thus it seems to me extremely fitting that the subject of gas producers should be given a fairly thorough treatment in any work written primarily as a text for chemical engineering students.

The subject is treated from the standpoint of description of an ideal producer, having reference to the governing factors in the design and operation of the various elements; the application of these principles in various commercially successful producers; and the methods by which the production and efficiency of a producer may be figured for varying conditions of operation.

In the compass of an extremely small space, sufficient information is clearly and correctly brought forward to satisfy the needs of all except the engineer who specializes in producer design or control. In accordance with the general scheme of the book, the chemical engineer is here presented with the basic facts which he needs to know about gas producers.

Of particular interest is the development of the production computation. The authors have here applied their special type of equation, which is of value in that it shows at all points what the unit is and provides an extremely easy expression to check in case of error. So many cases of confusion in figuring the production of gas-making equipment have come to the writer's attention that a grounding of the student in such a clear method seems the noteworthy point in this part of the book.

Fuels—Their Combustion and Apparatus

Since Fuel Is Basic to the Production of Heat, Its Use Is of Primary Importance to the Chemical Engineer

BY JOSEPH A. DOYLE
Vice-President W. S. Rockwell Co., New York City

THE chapters on fuels and power, combustion and furnaces and kilns present a constructive, definite and conservative analysis of the subjects in question. It is pleasing to note that the authors have definitely expressed their views without the usual qualifications that leave the reader in doubt.

The orthodox method of treatment in the usual considerations of fuels, power, furnaces, methods of heating, etc., is not as broad as it should be; perhaps we should be more concerned with the use made of heat than with the process of making it. After all, the chemical industry is, like the metallurgical industry, more concerned with the quality and the cost of the product than with an abstract consideration of fuels, combustion and equipment.

For these reasons, the chapters of this work such as that on furnaces and kilns, which deal with the equipment for utilizing heat, were of most

interest to me and afford an opportunity for future expansion promising much good for the art. While in many details my experience does not run exactly parallel to that of the authors, the book gives a good picture of the fundamentals and as a text for the beginner in the art of chemical engineering should prove a work of real value.

Humidity, Thermometry and Related Equipment

The Design and Use of Much Equipment of Great Importance to the Chemical Engineer Is Properly Founded on a Consideration of the Amount of Water Vapor Present in Some Gas

By C. H Kimberly
Binks Spray Equipment Co., New York City

The general plan of this part of the book is excellently worked out and indicates that it can be well adapted to use for a text where the details are explained by a person thoroughly familiar with the physics and mathematics of the subject. However, for use by a student or practical engineer handling the entire field of chemical engineering, the very thoroughness and length to which the authors have gone in dealing with this phase of the work have a great tendency to cloud the understanding of one searching for information.

The definitions are well worded and as complete as is required and give a clear knowledge of their subjects. The use of problems to explain the principles and operation of the practical side is admirable. The charts are, however, not sufficiently explained, or their lines defined, to allow of their being put to practical use without a detailed study of the authors' intention.

The illustrations are excellent and cover the distinctive types correctly; but a few others showing the application of spray cooling ponds, evaporators, etc., would be of great help if the volume is used outside the class room. The authors apparently have a thorough knowledge of the subject and have given it a deep and excellent treatment, and the book, if used under direction of a competent instructor and as a text book, should meet a decided need and be of much value.

Crushing, Grinding and Separation

A Subject of Growing Importance to the Chemical Engineer Is Well Covered in This Book

By Edward H. Robie
Assistant Editor Engineering and Mining Journal-Press

Crushing and grinding and the mechanical separation of materials form an important part of many chemical processes. The authors are well advised in devoting sixty-seven pages of the book to these subjects. After discussing briefly the theoretical side of crushing and grinding, the factors on which the selection of machines is based are outlined. Apparatus is logically classified in four divisions: preliminary breakers, intermediate crushers, fine crushers, and fine pulverizers. For breaking the largest pieces, jaw or gyratory crushers are ordinarily used, three forms of the former and one of the latter being described briefly. The Symons disk machine (incorrectly spelled "Symonds") is the only form of apparatus mentioned under the head of intermediate crushers, though the use of gyratories and rolls is somewhat more common for the size of feed included in this designation—i.e., 1½ to 2 in. Rolls, however, are described under the heading of fine crushers, along with rotary crushers, stamps and the Chilean mill.

The section on fine pulverizers includes descriptions of cylindrical and conical ball mills, tube mills, centrifugal roll mills, burr mills and disintegrators. Ball mills are extremely popular, particularly in the mining field, the Marcy and Hardinge types being described briefly. The ways in which the fineness of the product of a ball mill may be regulated are well stated, though exception might be taken to the statement, "There is a certain amount of grinding or shearing action taking place in the mill, due to rolling of the balls, but its importance is small compared with the action of the falling balls." I am inclined to think that attrition is the chief way that grinding is accomplished in a ball mill, particularly when the smaller sizes of balls are used.

Speaking generally of the chapters under review, the treatment may be said to be good though brief. For more complete data, such a book as Allen's "Handbook of Ore Dressing" or Truscott's "A Text-book of Ore Dressing" should be consulted.

Filtration—Theoretical and Practical

The Subject Is Covered From the Standpoint of Design, Operation and Utility

By Arthur Wright, M. E.
Filtration Engineers, Inc., New York City

Upon opening this chapter and thumbing over its pages the reader is confronted by a formidable array of mathematical formulas; differential and integral calculus that may well make him fumble back for facility to the math of his sophomore year. The chief interest of the chapter lies in its treatment of "filter calculations" and derivations of formulas.

In contrast to the skimpiness of some parts of this chapter, the paragraphs on "Filter Calculations" are not stinted. We must respect the mass of experimental work undertaken and the thoroughness with which it has been done. This is indeed most important in its endeavor to point the way from loose rule-of-thumb methods by reducing filtration principles to mathematical equations. The authors have made a considerable advance and their work can well be commended.

To sum up, the value of this book is academic, not practical, but it is none the less important for that. It is a real contribution to the art of filtration and should give rise to increased efforts to reduce to mathematical terms the varied performance of our present-day filtering apparatus

Materials and Accessories for Chemical Industries

High Temperature Refractory

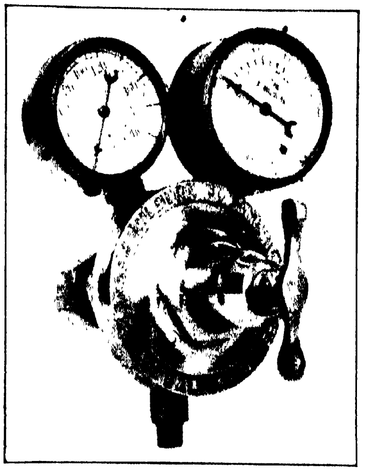
The Celite Products Co. for a number of years has had an insulating brick on the market known as "Sil-O-Cel," which has been used for the insulation of various types of furnaces, boilers, ovens, kilns, etc.

Quite recently this company has developed a calcined brick known as Sil-O-Cel C-22 brick, which is used for severe conditions where the unburned brick might be subjected to a temperature high enough to cause shrinkage. These C-22 brick are recommended for use where the insulation will be subjected to temperatures in excess of 1,650 deg. F. and can be successfully used without any danger of shrinkage at temperatures in excess of 2,000 deg. F. They are composed entirely of Sil-O-Cel and for this reason have a high insulating value. They also have an unusually high crushing strength for an insulating brick.

These brick are for service at extreme operating temperatures and are especially well adapted for use in the combustion zones of power boilers, in furnaces, kilns, etc., which operate at temperatures in excess of 2,500 deg. F.

Pressure Regulator

This is a new regulator for the purpose of regulating the control and delivery of acetylene, oxygen, hydrogen and other high-pressure gases. It is designed to maintain a constant predetermined pressure regardless of fluctuations in the initial pressure line and variations in consumption. This regulator is simple in design. The front cap contains an adjusting key, a top spring button and a tension spring. The body contains in front a flexible metal diaphragm, soldered on. Over this diaphragm is screwed a bronze diaphragm plate or spring button to hold the tension spring. Inside this body is a fixed nozzle containing a loose operating pin. Over the nozzle is loosely assembled the valve sleeve, which has a roll of gas ports drilled through its circumference and carries the valve seat. The seat closes against the nozzle by initial gas pressure on the valve sleeve and pressure of a compensating spring resting in the recessed tank coupling. The loose operating pin inside of the nozzle is actuated at one end by the deflection of the diaphragm and at the other by pressure of the valve sleeve.



MILBURN GAS REGULATOR

It will be noticed from the above description that the regulator closes with the gas pressure and not against it. This enables the sealing to be effected by pressure of several pounds instead of hundreds of pounds, as would be the case if the sleeve were yoked to the diaphragm. In this design the sleeve is entirely independent of the diaphragm. An equilibrium is maintained in the regulator at all times, throttling the supply when the desired pressure is built up and opening instantly when the consumption lowers the pressure and an increased supply is needed.

This regulator has been simplified in all particulars from the old design and has been reduced in size and weight. The valve seat is now subjected to much less wear and, being held in perfect alignment, it works with accuracy for many months longer than the seat of the old-style regulator.

Neither volume of gas nor accuracy of regulation has been sacrificed in simplifying the construction. On the contrary, the manufacturer claims for this regulator that it will act with more directness and regulate within closer limits, in addition to maintaining its efficiency of regulation for a longer and harder period of service.

The regulator is adapted for use with various gases by a change of the gages shown in the illustration. The rear connection is also changeable so that the regulator can be attached to various types of containers. This regulator is the invention of A. F. Jenkins, who has long been associated with the acetylene industry. It is manufactured and sold by the Alexander Milburn Co. of Baltimore, Md.

Catalogs Received

STEERE ENGINEERING CO., Detroit, Mich.—Pamphlet 246. Leaflet pointing out further information relative to this company's bulletin 39.

OXWELD ACETYLENE CO., Chicago, Ill.—How Welded Joints Solved Pipe Line Troubles. A book made up of reprints describing the use of oxy acetylene welding equipment as used in the petroleum industry, the city gas plant, long-distance high-pressure gas transmission, and industrial piping.

THE FOXBORO CO., Foxboro, Mass.—A new issue of the Foxboro Co.'s general catalog, including many recent bulletins of this company, issued under date of April, 1923. The subjects include all types of Foxboro recording and indicating instruments.

KNAPP METAL BARREL & PACKAGE CO. OF NEVADA, San Francisco, Calif.—Leaflet describing the Knapp knock-down metal barrel with locking head.

BROWN HOISTING MACHINERY CO., Cleveland, Ohio—Catalog F. A catalog describing the new Brownhoist single roll coal crusher. Catalog M. A catalog describing the new Brownhoist belt conveyor idler.

LINK-BELT CO., Chicago, Ill.—Book 480. A new Link-Belt catalog describing the company's line of electric hoists and overhead traveling cranes. This book is well illustrated with many suggestive applications of Link-Belt hoists and cranes.

CONTINENTAL PIPE MFG. CO., Seattle, Wash.—Catalog 18. A new and very complete catalog on various types of wood pipe and flumes manufactured by this company. The book is well illustrated and contains many tables of value to the engineer.

THE ESTERLINE-ANGUS CO., Indianapolis, Ind.—Bulletin 223. A bulletin describing various new uses for the Esterline type of graphic instruments.

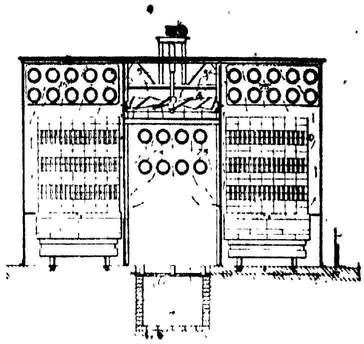
PENNSYLVANIA FLEXIBLE METALLIC TUBING CO., Philadelphia, Pa.—Bulletin 55-B. A new bulletin describing the "Penflex" type of all-metal heavy-duty hose and couplings for tank car unloading.

THE ROTO CO., Hartford, Conn.—A new catalog describing the Roto line of tube cleaners for boilers, economizers, condensers, evaporators, feed water heaters and other tubular equipment.

Review of Recent Patents

Developments of Interest to the Chemical Engineer

Drying, Catalysis and Crystallization Among Fundamental Processes Stressed in Recent Patent Specifications



A NEW WASTE HEAT DRIER

FEW UNIT PROCESSES in chemical engineering have been more intensively studied or more extensively developed than drying. Driers have been used for many years, but until quite recently their development has been empirical. Perhaps within the last decade modern drying has come into its own. It is, therefore, with rather unusual interest that patents on drying equipment are studied. W. M. Schwartz and E. B. Ayers, of Philadelphia, have patented a tunnel drier for drying bricks and other pottery materials before they are baked in a kiln. Among other interesting features, it utilizes the waste heat from the firing kiln to dry the pottery or brick.

The principle of the drier is illustrated in the accompanying diagram. It consists essentially of three longitudinal chambers, two drying chambers on either side and an intermediate circulating chamber in the center. The drier is heated in two ways. In the first place, hot air from the cooling zone of the kiln comes into direct contact with the bricks as they are dried, and again the flue gases from the kiln itself are led through the drying chamber in pipes, over which circulates the air that comes in contact with the bricks and dries them. The gases from the cooling part of the kiln enter from the

American Patents Issued May 15, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.*'s staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,454,870-871—Nitration Apparatus and Process for Nitrating Cellulose. H. V. Walker, Newark, N. J.

1,454,873—Method of Handling Gases and Product Containing Dissolved Gas. H. C. P. Weber, Pittsburgh, Pa., assignor to Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

1,454,874—Fractionating Column. H. C. P. Weber, Pittsburgh, Pa., assignor to Westinghouse Company.

1,454,916—Means for Separating the Liquid and Solid Components of Mixtures of Liquids and Solids. A. J. Arbuckle, Johannesburg, Transvaal, South Africa.

1,454,945—Acid Receiver. P. L. Pfannenschmidt, Jena, Germany.

1,454,959-961—Cellulose Ether, Cellulose-Aralkyl-Ether and Composition Containing Cellulosic Derivatives. Henry Dreyfus, London, England.

1,455,005—Process of Producing Anhydrous Metallic Chloride. B. S. Kirkpatrick, San Pablo, and F. S. Morgan, Berkeley, Calif., assignors to Standard Oil Co. of California.

1,455,015—Soap. F. C. Atkinson, Indianapolis, Ind., assignor to American Hominy Co., Indianapolis.

1,455,016—Process of Preserving Cotton Seed. F. C. Atkinson, Indianapolis, Ind.

1,455,059—Cooling Means for Exhaust Mains. J. Van Ackeren, Pittsburgh, Pa., assignor to the Koppers Co., Pittsburgh, Pa.

1,455,060—Process of Recovering Iron Oxide and Other Products From Spent Iron Sludge. C. V. Bacon, Mahwah, N. J.

1,455,072—Dehydration of Alcohol. H. E. Bue, Roselle, N. J., assignor to the Standard Development Co.

1,455,088—Electrically Operating Treating Chamber for Hydrocarbon Vapors and Gases. J. L. McCabe, Wichita, Kan.

1,455,139—Electric Dehydrator. F. W. Harris, Los Angeles, Calif., assignor to the Petroleum Rectifying Co., San Francisco.

1,455,156—Apparatus for Refrigeration. R. A. Willson, Spokane, Wash., assignor of one-half to F. N. Martin, Spokane.

1,455,181—Furnace Gas Producer. C. E. Wentzel, Dayton, Ohio, assignor to International Clay Machinery Co., Dayton.

1,455,200—Insulating Composition for Electrical Apparatus. F. J. Groten, Jr., Meriden, Conn., assignor to Conn. Tel. & Elec. Co., Meriden.

1,455,238—Drying Appliance. H. J. Bosch, New York.

1,455,254—Utilization of Edible Fats. M. Kahn, New York, assignor to Intraven Co., New York.

1,455,263—Method and Apparatus for Testing Gaseous Mixtures. G. Oberfell, Tulsa, Okla.

1,455,264—Easily and Neutrally Soluble Double Compounds of 1-Allyl-3.7-Dimethyl Xanthine. E. Preiswerk, Basel, Switzerland, assignor to the Hoffman-La Roche Chemical Works, New York City.

1,455,284—Burning Sulphur. H. S. Davis, Pittsburgh, Pa., assignor to Texas Gulf Sulphur Co., New York City.

1,455,299—Method of Evaporating Ammonia Liquor. F. F. Marquard, Clairton, and C. W. Littler, Swissvale, Pa.

1,455,309—Propulsive Blasting Explosive. A. J. Strane, St. Paul, Minn., assignor to the Atlas Powder Co., Wilmington, Del.

1,455,376-7—Process of Converting Oils and Apparatus Therefor. J. H. Adams, Flatbush, N. Y., assignor to the Texas Co., Houston, Tex.

1,455,392—Apparatus for Drying Charges for Shaft Furnaces. E. Diepschlag, Breslau, Germany.

1,455,414—Absorbing and Purifying Composition. J. C. Tate, Oakland, Calif.

1,455,436—Art of Filtration. G. H. Field, Culver, Ind., assignor to Standard Oil Co., Whiting, Ind.

1,455,437—Petroleum-Distillation Process. V. T. Gilchrist, San Francisco, Calif., assignor to Superior Process Refining Co., San Francisco.

1,455,448—Process of Manufacture of Diphenylenediketones From Anthracene Compounds. G. Peters, Worms, Germany.

1,455,456—Ball Mill. L. L. Sweet and M. Morley, Wallace, Idaho.

1,455,469—Method of and Apparatus for Separating Coal and Like Substances and Impurities Mingled Therewith. W. D. Althouse, Philadelphia, Pa.

1,455,471—Method of Preparing Pulp. C. Bache-Weig, Portland, Me.

1,455,486-7-8—Dyes of the Acridine Series and Their Manufacture (2 patents). Dyes of the Benzene-Napthalene-Acridine Series and Their Manufacture. H. Grünhagen, Berlin, Germany, assignor to the Chemical Foundation, New York City.

1,455,495—Mercury Derivatives of Aromatic Compounds and Process of Making Same. A. Klages, Magdeburg-Sudost, Germany, assignor to the Chemical Foundation, New York City.

1,455,505—Filtering Apparatus. W. Paterson, London, England.

1,455,508—Process of Making the Chlorinated Products of Methane. E. H. Riesenfeld, Freiberg, Germany, assignor to the Chemical Foundation, New York City.

1,455,509—Method of Refining Mixtures of Chlorides of Napthalenes Serving as Substitutes for Rosin. K. Rucker, Berlin, Germany, assignor to the Chemical Foundation, New York City.

1,455,527—Coke Oven. P. Gottart, Brussels, Belgium, assignor to the Belgian-American Coke Ovens Corp., Wilmington, Del.

1,455,544—Rubber or Rubber-Coated Article. L. Minton, Manchester, England.

1,455,546—Process of Treating Bitumen or Cellulose-Containing Substances. I. Moscicki, Lwow, Poland.

1,455,591—Process of Treating Paper Stock. F. P. Miller, Downington, Pa.

1,455,598—Aromatic Hydrocarbon Cement. W. S. Barrie and L. Chadwick, Selwyn, Queensland, Australia.

1,455,630 and 679—Preparation of Starch and Sulphuric Acid. J. A. Lloyd, Coventry, England, assignor to Courtaulds, Ltd., London.

1,455,642—Still. J. M. Mahoney, Houston, Tex.

1,455,655—Process of and Means for Tanning Hides. V. Peradotto, Gallenca, Turin, Italy.

1,455,707—Recovery of Ether. J. H. Brégeat, Paris, France, assignor to Brégeat Corporation of America, Wilmington, Del.

1,455,728—Process for the Removal of Water From Colloidally Dissolved Substances Such as Crude Peat, Coal Sludge and the Like. H. Horst, Uerdingen, Germany, assignor to Gesellschaft für Maschinelle Druckentwasserung mitbeschränkter Haftung, Uerdingen, Germany.

1,455,762—Process of Recovering Cork and Other Products From Bark. G. C. Howard, Seattle, Wash.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

floor of the circulating chamber by means of dampers, which can be regulated, and mix with the air that is being circulated by means of fans at the top of the circulating chamber. The accompanying diagram illustrates a cross-section of the kiln and shows the flue underneath the floor of the circulating chamber, through which the air is admitted to the drier. It also shows the pipes 23 and 25 which contain the flue gases from the kiln.

Bricks are loaded on cars that are pushed through the tunnel drier by means of a hydraulic ram, both sides being operated at the same time. The diagram does not show deflectors which control the flow of gases nor the stacks and headers by which the flue gases are led from the kiln through the drying chamber in pipes and on to the stacks. This is described in Patent 1,451,589, issued April 10, 1923, and assigned to Proctor & Schwartz of Philadelphia.

A Useful Idea in Producing Halogen Acids

When silicon tetrachloride is treated with water, silicic acid and hydrochloric acid are formed. This, however, does very little good in the manufacture of hydrochloric acid, because the silicic acid comes down as a gelatinous precipitate, which is practically impossible to handle on a commercial scale. On the other hand, this reaction might be useful if it took place at a temperature above the dehydrating point of silicic acid. Then the material would come down in a dry state and the hydrochloric acid would be evolved as a gas. This is substantially the process patented by F. S. Low of Niagara Falls and assigned to the Weaver Co. of Madison, Wis. In carrying it out, he suggests vaporizing the silicon tetrachloride with a blast of steam. The reaction then takes place in a chamber in which the temperature is kept well above the dehydrating point of silicic acid. The silica drops to the bottom and may be removed by means of a hopper, whereas the hydrochloric acid vapor is evolved through a system in which appropriate absorption can take place. (1,451,399, issued April 10, 1922.)

A Continuous Crystallizer

Another patent is interesting, as it involves a principle that is coming to the fore more and more—that of continuous crystallization of particles having a definite size. The crystallizer of Truman E. Stevens of Omaha, Neb., contains scrapers made of large wire or heavy bristle brushes. The fine crystals are thus formed on the surface of the tank, which is cylindrical, and are immediately brushed off by the brushes. This keeps the tank free from an insulating layer, allows rapid cooling, and feeds the whole tank with fine crystals which grow to larger crystals as they travel to the bottom of the crystallizer, where they may be removed through an appropriate chute. (1,450,992, issued April 10, 1923, and assigned to Potash Reduction Co., Hoffland, Neb.)

Catalysts Improved by Grinding

Metallic nickel used as a catalyst in the hydrogenation of fatty acids and their esters and glycerides can be produced by treating a nickel salt with metallic zinc, but the resulting nickel is only weakly catalytic. If, however, the zinc is used in granular form and the reaction takes place under grinding conditions, as for example in a ball mill, the resulting nickel powder has a very much higher catalytic activity. This process was patented by George A. Richter, and assigned to the Brown Co. of Berlin, N. H. (1,451,113, issued April 10, 1923.) It is further noted in this patent that nickel which is produced from nickel sulphate has a higher activity than that produced from nickel chloride. The precipitated nickel is settled out and is washed free from zinc salt solution, after which it is dried in an inert atmosphere or under vacuum.

Trend of Invention in the Paint and Varnish Industries

Byproduct Recovery and Special Paints and Enameling Compositions Are the Subject of Late Patent Developments

AT LEAST six of the many patents issued during the month of March and April are of interest to the paint and varnish industries. Paul W. Webster, of Perry & Webster, New York, has described an oxidizable oil that can be recovered from the fume-collectors over paint and varnish heating kettles. The product he obtains is useful as a froth-producing material to be used in the flotation process. A non-corrosive paint consisting essentially of ferric oxide, zinc oxide and copper oxide is the subject of a patent by A. C. Tutt and Levi F. Snelson. A pure white paint "of a lasting, permanent nature which will be proof against the action of fire, acid, sun, water and rust" is specified in a similar patent by John T. Lawrence. Two of the patents refer to varnish gums. James McIntosh has patented a synthetic gum made by the condensation of a phenolic body with a ketone. Carleton Ellis' patent relates to a paint the vehicle of which contains cumaron resin. This paint dries to a flat or dull surface in contrast with the glossiness of ordinary paint. Herman F. Willkie, of the U. S. Industrial Alcohol Co., has obtained a novel enameling composition containing pyroxylin, which, although applied as a single coat, dries to form a dense opaque surface, very much like the highly glossed surface obtained with varnish.

Recovering a Marketable Byproduct

In paint and varnish manufacture various types of drying oils, such as linseed, tung, china wood and soya bean oils, are boiled together with the resins, gums and pigments in kettles, which are usually provided with fume-collection equipment. These fumes given off consist of various vapors and volatile oils, together with some comparatively permanent gases. Examination of these fumes has shown that they contain an oil distillate that may be separated by condensation. The condensers consist of tubes cooled by means of air or various liquid refrigerants. By drawing air into the condensing tubes the distillate is oxidized during the time it is condensing. The stable liquid obtained from these condensers is an air-drying fatty oil, with a condensing point below 75 deg. F. (1,447,954, issued March 6, 1923.)

Non-Corrosive and Special Paints

An example of the non-corrosive paints obtained by Tutt and Snelson is made by mixing 70 parts of dry ferric oxide, 10 parts of dry zinc oxide and 10 parts of copper oxide and thoroughly incorporating them with about 60 parts of raw linseed oil. Small quantities of either waste or reclaimed rubber and of raw amber are also incorporated with the oil and form a part of the paint. The rubber gives an adhesive quality, while the amber supplies the gloss. (1,448,284, issued March 13, 1923.)

The formula for the paint made by Lawrence is as follows: Poppy seed oil 80 parts, barium sulphate 12 parts, sodium carbonate 12 parts, prepared white zinc oxide 24 parts, white lead 12 parts, zinc sulphate 16 parts, silica 12 parts, ground white antimony 6 parts, commercial yellow rosin 6 parts, and water-white rosin 6 parts. All of the ingredients except the rosin are mixed together at approximately 600 deg. F. for about half an hour. The non-corrosive properties of this paint are claimed to apply for both wood and metal surfaces. (1,450,688, issued April 3, 1923.)

Synthetic Gum and Cumaron

The patent on synthetic gum, which is assigned to the Diamond State Fibre Co., provides for the condensation of phenol, or a phenolic body, with a ketone such as acetone or methylethylketone, in the presence of sulphuric acid, bromine, sulphur, pyridine, or any other suitable catalytic agent. The resulting gum after it has condensed to a solid form is placed on an oven and subjected to a temperature of from 120 to 130 deg. C. for from 10 to 12 hours. A yellow or orange gum having a melting point of about 80 deg. C. and a high luster is obtained which is especially valuable as a shellac substitute. It is soluble in alcohol, benzol, acetone and most other organic solvents, although it is insoluble in water. (1,448,566, issued March 13, 1923.)

The patent by Carleton Ellis provides

for the use of a 33 to 45 per cent solution of hard cumaron resin (m.p. 90 deg. C.), which is mixed with 5 lb. lithopone and put through a paint grinder. This paint thus obtained when applied to a wooden or other surface dries to a flat finish. For a red color, iron oxide may be used instead of lithopone, the following proportions being necessary: 225 lb. mineral red, 57 lb. cumaron resin and 80 lb. heavy benzine. The use of various other pigments, such as ocher, umber and brunswick green, may be desirable in order to obtain a variety of colors. (1,451,092, issued April 10, 1923.)

Pyroxylin Enameling Composition

The object of the patent by Willkie was to provide a composition that would give an enameled surface, similar to varnish, by the application of a single coat. The enameled coating obtained by this composition, although it is applied as a single coating, is in reality made up of a lower layer of a dense opaque character and an upper varnish-like layer that gives the coated surface a high gloss. A cellulose ester such as pyroxylin is dissolved in a solvent mixture made up of 75 per cent by volume of ethyl alcohol having a strength of approximately 90 per cent, 23.75 per cent of anhydrous ethyl acetate and 1.25 per cent of diethyl phthalate. The last named is the so-called high-boiling solvent and it remains in the upper part of the hardened film as a latent solvent of the cellulose ester, thus cementing together the particles of precipitated ester, which form the lower layer of the coating.

It is pointed out that other cellulose esters, such as cellulose acetate, may be used and that the ethyl acetate and alcohol may be replaced by various solvents such as acetone, methyl acetate, etc. Furthermore, the diethyl phthalate may be replaced by various other compounds, such as ethyl aceto acetate, triacetin, etc. (1,449,157, issued March 20, 1923, and assigned to U. S. Industrial Alcohol Co.)

Synopsis of Recent Literature

Foundations and Floors

The subjects of foundations, floors and ceilings is a highly important one to the executive who contemplates industrial building. G. L. H. Arnold, in his series on "Buildings From the Manager's Viewpoint," in *Management Engineering* for May, 1923, points out that good foundations properly supported, floors of ample strength and ceilings free from obstructions are prime requisites of the good factory building.

Foundations — The foundation must first be strong enough to bear the building load. It must be supported in such a way that settlement is reduced to a minimum and cracking prevented. To attain this latter point bearing surfaces must be ample and, if the soil is poor in bearing qualities, piling must be used. Finally, foundations must be properly waterproofed to a point well above the water line.

Floors — The points to consider in flooring, after the prime one of adapting the floor material to the type of manufacture to be conducted in the building, are:

1. It should be smooth, and free from nails, bolts and other projections; also from holes and splinters.

2. It should be dry, of low heat conductivity, durable, and easily cleaned.

3. It should be constructed strongly enough to bear at least four times the static load, and six times the moving load which may be placed upon it.

4. It should be as nearly noiseless as possible. Noisy floors may wear well, but the noise of the feet, truck wheels and machinery irritates the workmen.

5. It should not be slippery, nor made of material which will wear slippery.

6. Regular inspection of floors should be made and defects repaired promptly.

Ceilings— Lighting and the probable requirements for pipes, shafting and belts will be the important factors to be considered in connection with the ceilings. For lighting purposes the flat slab ceiling is best, while if much piping and shafting is to be run the beamed type with its smaller column heads is better. In general, a proper compromise must be made to suit the particular industry.

Seaboard Liquid Purification Process

An answer to the paper of R. H. Broker, recently published by *Gas Age-Record* and synopsized in these pages, from the pen of F. W. Sperr, Jr., of the Koppers Co., appears in *Gas Age-Record* for May 19. Mr. Sperr says in part:

The paper by Mr. Broker is to be welcomed as a frank statement of the difficulties likely to be encountered by a gasworks management which undertakes to design and build its own liquid purification plant. It should perhaps have been stated plainly in the paper that, at the request of the Racine management, the design and construction of the plant were done by themselves locally; but doubtless Mr. Broker intended that this should be brought out in the discussion. In fairness to the "Seaboard process," it should be emphasized that there are five other plants in operation using the process under all sorts of conditions, and that these are all operating with a high degree of efficiency and to the satisfaction of their owners.

From the local conditions at Racine,

Important Articles In Current Literature

More than fifty industrial technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

MITSCHERLICH PULP. Arthur S. M. Klein. *Paper Trade Journal*, May 17, 1923, Technical Section, pp. 180-184.

FINDING STEAM LOSSES FROM STEAM COSTS. S. H. Childs. *Paper Trade Journal*, May 17, 1923, Cost Section, pp. 52-53.

DENATURED ALCOHOL IN CANADA. Ross E. Gilmore. *Canadian Chemistry and Metallurgy*, May, 1923, pp. 116-118.

CANADA'S CHEMICAL TRADE. S. J. Cook. *Canadian Chemistry and Metallurgy*, May, 1923, pp. 135-138.

TURPENTINE. G. H. Pickard. *American Paint Journal*, May 14, 1923, pp. 18-22.

THE ELECTRON IN CHEMISTRY. Sir J. J. Thomson. *Journal of the Franklin Institute*, May, 1923, pp. 593-620.

HIGH TEMPERATURE INVESTIGATION. E. F. Northrup. *Journal of the Franklin Institute*, May, 1923, pp. 665-686.

STAINLESS STEEL. *Engineering*, May 4, 1923, p. 550.

SOME EFFECTS OF ZIRCONIUM IN STEEL. F. M. Becket. *Iron Age*, May 10, 1923, p. 1321.

SURFACE COMBUSTION. W. A. BONE. *Engineering*, May 11, 1923, p. 594.

THE DESIGN OF HOT-AIR DRYING PLANT. George H. Gill. *Engineering* (London), May 4, 1923, pp. 541-542.

SEABOARD LIQUID PURIFICATION PROCESS. F. W. Sperr, Jr. *Gas Age-Record*, May 19, 1923, pp. 639-640.

RINCKER COMPLETE GASIFICATION PLANT. *Gas Age-Record*, May 19, 1923, pp. 637-638.

LES APPLICATIONS INDUSTRIELLES DE LA CATALYSE EN CHIMIE ORGANIQUE. A. Mailhe. *La Technique Moderne*, May 1, 1923, pp. 257-264.

inferences are drawn by Mr. Broker against the efficiency of the process. At present writing, one of the five other plants is removing 82 per cent of the hydrogen sulphide in the gas; the others are removing from 90 to 95 per cent of the hydrogen sulphide. All of these plants are removing 90 per cent or more of the hydrocyanic acid in the gas. In the case of the single plant with 82 per cent efficiency of H_2S removal, changes will be made which will increase this to 90 per cent. For plants which it designs and builds the Koppers Co. is willing to guarantee an efficiency of at least 85 per cent.

The only other important point raised by Mr. Broker is the question of the odor of the actifier air. There has been no disposition on the part of the Koppers Co. to minimize this.

The expedient of burning the actifier air, as practiced at Battle Creek, is undoubtedly the surest way of avoiding complaint; but in certain cases the Koppers Co. has recommended dilution, and with ample ground, in spite of Mr. Broker's statement. One plant located in the midst of an important business district and close to offices and dwellings has employed dilution for nearly a year as the sole method of disposal of the actifier air, and has had no complaint and no indication of objectionable odor. Three other plants located farther away from business or residence district discharge the actifier air directly into the atmosphere and have had no complaint.

The height of the point of discharge above the ground is undoubtedly important; and with a sufficiently high stack, dilution may in many cases be the most satisfactory means of getting rid of the actifier air. It should be brought out in this connection that when the Racine plant was first started they had a wooden stack only 30 to 35 ft. high—in fact, not so high as the purification tower. It was during this period that practically all of the odor trouble occurred.

Men in the Profession

R. F. BOWER, a statistical expert in fertilizers and fertilizer materials, has been appointed to assist in the nitrate studies of the Department of Commerce. Mr. Bower will give particular attention to the agricultural demands for nitrogen.

C. G. DARWIN, grandson of Charles Darwin, recently addressed the Southern California Section of the American Chemical Society, at Los Angeles, on "The Periodic System." Mr. Darwin has been appointed to the new Tait chair of natural philosophy at Edinburgh University.

J. WALTER DRAKE, an automobile manufacturer of Detroit and a native of Sturgis, Mich., has been selected to fill the vacancy in the office of the Assistant Secretary of Commerce created by the resignation of Claudius H. Huston.

A. C. FIELDNER, supervising chemist and superintendent of the Bureau of Mines Experiment Station, Pittsburgh, Pa., gave a lecture before the Mining Society of Pennsylvania State College, State College, Pa., May 4, on "The Constitution of Coal."

L. W. HIMMLER has resigned as assistant chemist in the Dairy Division, Bureau of Animal Industry, at Washington, D. C., to join the research staff of the Cudahy Packing Co., at Omaha, Neb.

S. P. HOWELL has been assigned to work in connection with the field investigation of liquid oxygen explosives for the Bureau of Mines.

RAYMOND B. LADOO, mineral technologist of the Bureau of Mines, has resigned that position to go with the Southern Mineral Co., Washington, D. C. He will devote his attention to the development work in connection with the non-metallic minerals in the Southern states.

ERIC A. LOF, who since 1909 has been connected with the power and mining engineering department of the General Electric Co. as industrial engineer and specialist, has resigned to take up work with the American Cyanamid Co., with headquarters in New York City. He will assume his new duties June 1.

RONIER D. OILAR, chemical engineer, returned recently from a trip to South America, having spent a little over a year in development and investigational work on vegetable oil, soap and packing-house industries in Peru and several other countries.

BRADLEY STOUGHTON, formerly secretary of the American Institute of Mining and Metallurgical Engineers and more recently consulting engineer, will, beginning next fall, be professor of metallurgy at Lehigh University, Bethlehem, Pa.

Obituary

HENRY WOODLAND, secretary and treasurer of the Allis-Chalmers Manufacturing Co., died suddenly at his home in Milwaukee, May 14. Born in Utica, N. Y., Mr. Woodland at an early age became connected with the New York Air Brake Co. of Chicago. When in 1901 this company was taken over in the consolidation which formed the Allis-Chalmers company, he became assistant treasurer of the new organization and afterward its treasurer. In 1916 he was elected secretary and treasurer. At the time of his death he was also vice-president and a director of the Hanna Engineering Co. of Chicago.

Calendar

AMERICAN ASSOCIATION OF CEREAL CHEMISTS, ninth annual convention, Hotel Sherman, Chicago, June 1 to 9.

AMERICAN CHEMICAL SOCIETY, fall meeting, Milwaukee, Wis., Sept. 10 to 14.

AMERICAN CHEMICAL SOCIETY, New York Section, regular meeting, Rumford Hall, Chemists' Club, June 8.

AMERICAN ELECTROPLATERS SOCIETY, eleventh annual meeting, Providence, R. I., July 2 to 5.

AMERICAN GAS ASSOCIATION, annual convention, Atlantic City, Oct. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, summer meeting, Wilmington, Del., June 20 to 23.

AMERICAN LEATHER CHEMISTS ASSOCIATION, twentieth annual convention, Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION, annual meeting, Springfield, Mass., May 31 to June 2.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, spring meeting, Montreal, Canada, May 28 to 31.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS, iron and steel exposition, Buffalo, N. Y, Sept. 24 to 28.

AMERICAN SOCIETY FOR TESTING MATERIALS, twenty-sixth annual meeting, Chalfonte-Haddon Hall Hotel, Atlantic City, June 25 to 30

CANADIAN INSTITUTE OF CHEMISTRY, annual meeting, Toronto, May 29 to 31.

INSTITUTE OF MARGARIN MANUFACTURERS, fourth annual convention, Hotel Traymore, Atlantic City, June 14 and 15.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH), New York, Sept. 17-22.

NATIONAL FERTILIZER ASSOCIATION, thirtieth annual convention, White Sulphur Springs, W. Va., June 11 to 16.

NATIONAL LIME ASSOCIATION, fifth annual convention, Hotel Commodore, New York City, June 13 to 15.

SOCIETY OF CHEMICAL INDUSTRY, Canadian Section, Toronto, May 29 to 31.

SOCIETY FOR STEEL TREATING, Eastern sectional meeting, Bethlehem, Pa., June 14 and 15.

TAYLOR SOCIETY, Hotel Onondaga, Syracuse, N. Y., June 7 to 9.

Industry and Trade

Current News and Market Developments

Summary of the Week

Oliver Bowles, mineral technologist, appointed to head new non-metals experiment station of Bureau of Mines at Rutgers College.

Brief course in chemical engineering planned for benefit of students attending Ninth Annual Chemical Industries Exposition.

Lehigh engages Bradley Stoughton as professor of metallurgy.

Importers are carrying heavy stocks of chemicals and are finding it difficult to maintain prices.

Report from Washington states that annual coal-tar census will soon be ready for publication.

Official import figures for February show that arrivals of chemicals for that month suffer in comparison with totals for corresponding period last year.

Tariff Commission is considering establishment of a permanent staff in foreign countries.

Report from Germany casts doubt on belief that importers of coal-tar products will secure regular shipments from that country.

Imported caustic potash offered freely with prices gradually working lower.

Lower prices for tin have resulted in a 2c. per lb. decline in tin oxide.

Bureau of Census figures on cottonseed products brought about higher prices for cottonseed oil.

C. P. glycerine unsettled on freer offerings from midwest producer.

Turpentine lowered in price as result of large receipts at southern terminals.

Phenol offered in a larger way by second hands and at reduced prices.

Heavy arrivals of crude naphthaline from abroad and lower cables from foreign centers created easier feeling.

Yellow prussiate of soda offered at reduced prices for June delivery with spot market also easier.

German Coal-Tar Industry Affected by Lack of Fuel and Raw Materials

Majority of Producing Plants Located in Occupied Territory—Coal Shortage Closing Works

"THE statement of leaders of the German coal-tar dyes industry that, by reason of stocks on hand either at the works or with dealers in that country or abroad, Germany is probably able to supply demands for the next 6 months should be taken with reserve," declares William T. Daugherty, assistant trade commissioner of the United States at Berlin, in a report to the Department of Commerce dated April 5, 1923.

It is estimated that 80 per cent of the total production of coal-tar dyes, considered alone, is located in occupied territory, the report states, and plants have had difficulty in securing fuel and raw materials owing to refusal to pay the tax imposed by the occupational authorities. The main seats of five of the eight concerns in the "Interessengemeinschaft" of the German coal-tar dyes industry, which pool is practically a monopoly of that industry in Germany, are in occupied territory. Four of the large plants have been seized by the French and Belgians since the trade commissioner's report was prepared.

It has also been estimated, the report states, that 50 per cent of Germany's total production of pharmaceuticals, considered alone, is likewise located in occupied territory.

When the report was prepared, it was reported that the works on the upper Rhine belonging to the Badische were having difficulties in getting fuel. The Badische plant at Ludwigshafen was said to be virtually closed, while its other plants were embarrassed by a coal shortage. Fresh supplies were said not be forthcoming on account of the operators refusing to pay the French export tax. The Hoechster works were reported to be operating in very limited measure; while the same applied to the works of Bayer, at least in its works at Elberfeld, although its Leverkusen plant, in the English zone, was reported in a more favorable position. The Leverkusen works was said to be using brown coal, mined within English-occupied territory.

The report gives figures showing the decline in exports of German coal-tar dyestuffs, largely due, it is said, to development of the industry in the United States. In metric tons, these figures show that in 1913 exports from Germany of anilin and other tar dyes were 64,288; in 1920, 17,899; in 1921 (8 months only), 14,308; in 1922, 36,011. In 1913 exports of alizarin dyes from anthracene were 11,040 metric tons; in 1920, 3,325; in 1921 (8 months only), 1,570 and in 1922, 1,777 metric tons. In 1913, exports of artificial indigo were 33,353 metric tons; in 1920, 6,509; in 1921 (8 months only), 6,033; and in 1922, 13,828 metric tons.

Dr. Albert Neuburger in a leading article in *Chemiker Zeitung* of April 5 discussed the effect upon the chemical industry of occupation of the Ruhr and urged more general employment of known processes to recover combustible substance from the slag waste from the firing process as one means of overcoming the coal shortage.

The Ruhr occupation has caused German interests to view with pessimism the prospects of producing synthetic nitrogen this year, as first proposed to help overcome the domestic food shortage, Mr. Daugherty reports. The Oppau works shut down about April 1 because of coal shortage and had been credited with a production of 75,000 tons of nitrogen, or about 22 per cent of the total estimated production possible. The needs of German agriculture alone are estimated at between 420,000 and 600,000 tons of nitrogen annually. Under normal conditions and with proposed extensions, it is estimated that production could be increased 50,000 tons a year, and in 5 years the maximum demand could be filled. Despite encouragement of imports, little saltpeter was imported from Chile last year.

Mines Bureau Opens Non-Metal Station With Oliver Bowles as Director

New Brunswick, N. J., Selected as Home for New Experiment Station, Due to Central Location and Available Facilities

RUTGERS College, New Brunswick, N. J., has recently been designated by the Secretary of the Interior as the location for the new non-metal experiment station of the Bureau of Mines.

Oliver Bowles, the mineral technologist, who has been in immediate charge of the bureau's work on the non-metals, has been selected to be superintendent of the new experiment station. Mr. Bowles is a Canadian by birth, but has been continuously engaged as an educator and government specialist in this country since 1908. In 1908 and 1909 he served the University of Michigan as an instructor in petrography. For the 4 years following, he taught geology and mineralogy at the University of Minnesota. He joined the staff of the Bureau of Mines in 1914 as a quarry technologist and since 1917 has been the mineral technologist for the Chemical Division of the bureau.

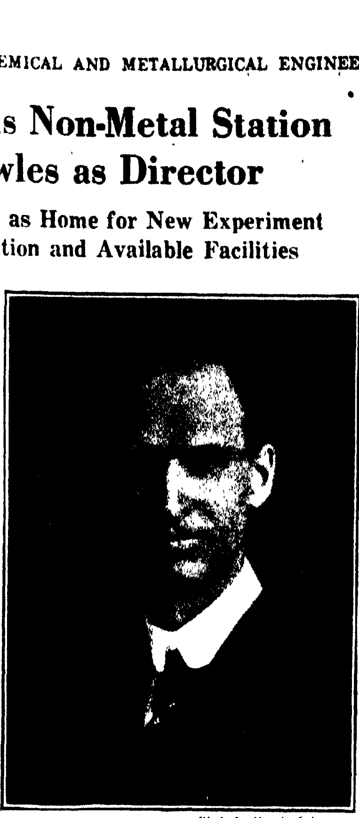

Photo by Harris & Ewing

OLIVER BOWLES

The new station will specialize in problems involved in the production and utilization of the non-metallic minerals. Of these minerals the most important at present are bauxite, cement, clay, feldspar, fullers earth, graphite, gypsum, lime, mica, phosphate rock, salt, sand and gravel, sand-lime brick, slate, stone, sulphur, mineral paints, garnet, asbestos and talc. The value of these non metallic minerals produced annually in the United States is in the neighborhood of a billion dollars.

Before recommending a location for this station, a very careful survey of the entire country was made by the Bureau of Mines. New Brunswick finally was chosen because nearly all of the talc output of the country is produced in the North, as is two-thirds of the feldspar, three-fourths of the silica, nine-tenths of the slate and three-fourths of the building stone. In addition, the gypsum, refractories, fluxing stone, monumental stone and dolomite output is confined almost entirely to the North. This makes New Brunswick a very central location with reference to the production and consumption of the non-metallic minerals. The total production of non-metals north of the Potomac is $245,000,000 and $92,000,000 south of the Potomac. The adjacent state of Pennsylvania, alone, has one and seven-tenths times as great a production of non-metallic minerals as have all of the states south of the Potomac and Ohio rivers combined.

Bradley Stoughton to Join Lehigh Staff

Bradley Stoughton, inventor of furnaces used in steel plants, writer on metallurgy and engineering, until recently secretary of the American Institute of Mining and Metallurgical Engineers and a prominent New York consulting engineer, has been appointed professor of metallurgy at Lehigh University. He succeeds in this capacity Prof. Joseph W. Richards, who died Oct. 12, 1921.

Mr. Stoughton has had teaching experience, for he was for some years acting head of the department of metallurgy at Columbia University. He has been connected with the Illinois Steel Co., the American Steel & Wire Co. and Benjamin Atha & Co., Newark, N. J. He became a consulting engineer in 1902.

Centrifugal Study Planned by Bureau of Mines

The advisability of taking up intensive research in connection with the use of centrifugal force in the concentration of ores, the thickening of pulp and the dewatering of various mill products is being considered by the Bureau of Mines. Before taking this step, however, bureau officials are anxious to get in touch with other investigators.

There is full recognition of the part of the bureau specialists of the difficulties on the mechanical side of centrifugal operations as well as of the other obstacles that must be surmounted. However, in view of the great advantages that would follow the successful application of this great force to the treatment of ores, there is a definite inclination to enter upon research along these lines.

Smaller Rosin Carry-Over Into New Crop Year

Turpentine Stocks, However, Are Larger Than in Preceding Statistical Period

The annual canvass of the stocks of turpentine and rosin on hand at the end of the crop year, which closed March 31, has been completed by the Bureau of Chemistry of the Department of Agriculture. The totals, as shown in the canvass, include supplies of turpentine and rosin held by and en route to factors, dealers and jobbers—but not consumers—at the primary ports and the important distributing points of the country.

The figures are shown in the following table:

	Turpentine Casks April 1, 1923	Turpentine Casks April 1, 1922
Southern primary ports	21,040	24,099
Eastern ports	2,652	1,675
Central distr. points	10,881	8,195
Western points	2,225	900
Total stocks	36,798	34,869

	Rosin, Round Bbls. April 1, 1923	Rosin, Round Bbls. April 1, 1922
Southern primary ports	278,414	349,730
Eastern ports	8,078	11,359
Central distr. points	46,938	49,043
Western points	1,340	6,447
Total stocks	334,770	416,579

In order to be more complete, the figures for stocks at the Southern primary ports include the total receipts during the first week of April at Savannah, Jacksonville and Pensacola, and an estimate of the same for the other ports, as representing, as nearly as can be judged, the quantity of turpentine and rosin which had already left the stills on April 1 and was en route to the ports. This material would not be included in the stocks held by producers at the stills, which will be shown in a later report. The figures which have thus been added in are as follows: for Savannah, 825 casks turpentine and 2,554 bbl. of rosin; for Jacksonville, 1,318 casks turpentine and 9,332 bbl. of rosin; for Pensacola, 290 casks turpentine and 1,499 bbl. of rosin; for Brunswick, Mobile and New Orleans, a total of 400 casks turpentine and 1,200 bbl. rosin.

German Potash Production at Minimum Capacity

Germany's potash properties are being worked at the minimum capacity allowed by law. Much of the work is confined to development. One of the government's consulting specialists, who has just returned from Germany, is convinced that the potash interests are sincere in their desire to reduce the price of potash to the point where its use will be greatly extended.

Under present conditions the German nitrogen plants are finding it extremely difficult to compete successfully with nitrate of soda from Chile. As a result production of synthetic nitrogen has been greatly reduced, this specialist reports.

Chemical Imports in February Fall Far Below January Totals

Coal-Tar Chemicals Did Not Share in Decline—Arrivals of White Arsenic Also Larger Than in January

IMPORTS of free list chemicals and allied products in February were valued at $6,954,847. The total value of those imports on the dutiable list was $2,629,664. This is a decided falling off from the January figures, when the value of free list imports was $9,155,648 and of dutiable imports $3,584,225.

The general decrease in imports did not apply to the coal-tar chemicals In fact, there was a slight increase in that total. In February these imports at all ports were valued at $1,193,361. In January, the total was $1,168,438 There was a decrease, however, in colors, dyes, stains, color acids and color bases. The February total was 200,094 lb., a decrease of 185,000 lb. as compared with January.

Imports of paints, pigments and varnishes during February were valued at $217,104. This is more than $100,000 less than the value of January imports. The February imports of fertilizers aggregated 142,350 tons, a reduction of more than 50,000 tons as compared with January.

One of the few items showing an increase was that of creosote oil. During February 5,530,443 gal of that commodity was brought into the country, a very material increase over January, when imports totaled 3,826,789 gal. The steady increase in imports of white arsenic continued during February, when the total brought from other countries reached 2,115,339 lb In January the total imported was 1,879,639 lb. There was a decided upturn in sulphuric acid imports in February, when the total reached 2,895,670 lb., as compared with 1,340,780 lb. in January.

The February imports of cyanide of potash amounted to 525,433 lb., an increase of 300,000 lb. over January. Even a more decided increase took place in the imports of sodium cyanide. The February total reached 2,633,133 lb.. or 650,000 lb. more than was imported in January.

The figures are those of the Bureau of Foreign and Domestic Commerce. Their compilation has been delayed since the enactment of the new tariff bill.

High-Grade Fertilizer Used This Season

Reports from the nineteen Middle West, Northern and Eastern States whose agronomists last winter voted to recommend high analyses mixed fertilizers show that a large proportion of the sales of commercial fertilizer this spring have been of these high analyses, according to officers of the soil improvement committee of the National Fertilizer Association.

In New York, which has an average normal consumption of 400,000 tons of commercial fertilizer annually, it is said that sales outside the five high analyses indorsed by the experiment station officials of that state have been very small. New York selected the smallest list of grades of any of the states which joined the movement to eliminate the low-content mixtures from official recommendations.

Peliminary reports indicate also that sales of fertilizer this spring have been greater in volume than last year and that there has been a substantial increase in the proportion of cash sales. Prices have been lower.

News Notes

Pasteur's memory is being honored in France by a series of meetings commemorating the one hundredth anniversary of his birth. At the first meeting U. S. Ambassador Myron Herrick presided and stated that Pasteur had accomplished more to abolish suffering than any other man in history.

Hampered standardization of weights and measures throughout the country is being caused by the lack of state appropriations for this work. At the sixteenth annual conference held on weights and measures at the Bureau of Standards last week this fact was reported by nearly every state except New Jersey.

Monel metal gauze for flame lamps to be used in gaseous or coal-dust laden atmospheres has been recommended by the Bureau of Mines. Unlike steel, Monel metal does not corrode badly in the atmosphere of damp mines.

Ether production in British Guiana has begun in the plant of an American company. This plant is of particular interest in connection with the development of the new industry for the production of alcohol motor spirit. This industry is enjoying rapidly brightening prospects in countries distant from petroleum production.

Germany's glass industry is in poor condition due mainly to the intense competition of the Belgian and Czecho-slovak industries. The inland demand and exports fell off one-third in April, with the result that many ovens were shut down altogether.

Biological topics featured the meeting of May 24 for the Southern California Section of the A.C.S., which met at Los Angeles. I. Grageroff, H. L. White and M. C. Terry were the speakers.

Tuberculosis treatment based on the use of an alkaline glycerol extract of steapsin or lipase, combined with a small amount of chloroform, is being studied at the Colorado School of Mines. Dr. L. G. Robinovitch, who is conducting the work, reports positive progress on the work so far undertaken,

Important zinc lands in Oklahoma have recently been purchased by the Schwab interests. Since 70 per cent of the country's zinc production, according to Mr. Schwab, is consumed by the steel industry, it is good business policy to have in its own hands a portion of the production of the raw material.

The dye importers' organization, reported some time ago as being under consideration, has not yet taken form, although meetings of parties interested have been held. It is expected that this week's meeting may answer the question of the form of the organization to be adopted.

Hydrocyanic acid may be used successfully in destroying animal pests in their burrows, according to recent Agriculture Department findings. The deadly nature of the gas and the need of caution in handling both it and the ingredients used in its production are emphasized, although it is stated there need be no hesitancy in using this as an anti-rodent if precautions are taken.

Several industrial films prepared by the Bureau of Mines are to be shown at the International Mining Exhibition in London. Copies of the following films have been sent: Story of Coal, Story of Petroleum, Story of Sulphur, Story of Ingot Iron, Story of Rock Drilling, Story of Asbestos, and Story of Alloy Steel.

The sum of $35,000 has been awarded in fellowships and scholarships in the Yale Graduate School for the coming year. Twenty-six fields of study will be represented by this group, the largest numbers being in English, 21; chemistry, and physiological chemistry, 13; history, 11; geology, 10; education, 7; and social and political science, 7.

Carnegie Tech Working on Oil Sludges

The elimination of sludge in turbine engine lubrication is receiving considerable attention at present in the research laboratories of Carnegie Tech. The occurrence of sludge in turbine lubricating oils has in the past greatly cut down the efficiency of these units. Dr. J. H. James is working with Prof. K. K. Stevens in studying the factors involved. Sufficient progress has already been made to allow Dr. James to make the following statement:

"A striking result of our preliminary experiments wa[illegible] all of [illegible] sludge compounds that we examined showed the presence of fatty acids, proving that the hydrocarbons of the mineral oils had been oxidized. These fatty acids were usually present in the form of metallic soaps. Examination of the sludge leads us to believe that these soaps are really forming greases which comprise the major portion of most of the sludges examined."

Small Stocks of Cottonseed Oil for Remainder of Crop Year

Monthly Consumption Averages 212,000 Bbl.—Seed Receipts at Mills Smaller Than Expected—Visible Supply of Oil Less Than at Corresponding Period Last Year

THE statistical position of cottonseed oil, according to an analysis of the April report of the Bureau of Census covering all cottonseed products, is extremely tight and tends to confirm opinion favoring a rather high level for prices over the remainder of the crop year. The consumption of cottonseed oil during April reached the total of 151,250 bbl., which compares with 110,000 bbl. in April a year ago. The figures were in line with private estimates and indicated that cheap lard did not seriously curtail business. The visible supply was reduced to 720,000 bbl., which compares with 861,000 bbl. on the last day of April a year ago.

Receipts of cottonseed were disappointing, the arrivals at the mills during April amounting to only 21,131 tons. Receipts of seed at the mills from Aug. 1, 1922, to April 30, 1923, amounted to 3,188,881 tons, against 2,871,143 tons for the corresponding period a year ago. The amount actually crushed for the 9 months ended April 30 was estimated at 3,132,666 tons, contrasted with 2,922,230 tons for the corresponding period a year ago.

Stocks of Crude Oil

The Bureau of Census reports production of crude oil for the August-April period at 962,580,720 lb., while for the same period a year ago the production figures were placed at 903,166,622 lb. Production of refined cottonseed oil for the 9 months ended April 30 amounted to 835,584,067 lb., against 790,768,610 lb. for the corresponding period a year ago.

Stocks of cottonseed at the plants on April 30 were estimated officially at 64,752 tons, which compares with 46,140 tons on the same date a year ago. The stocks of crude oil on the last day of April amounted to 37,484,169 lb., against 31,848,336 lb. a year ago.

The stocks of refined cottonseed oil at the plants on April 30 amounted to 236,001,125 lb., which compares with 302,079,057 lb. on the last day of April a year ago.

Consumption of cottonseed oil for the past 9 months shows an increase of 117,000 bbl. contrasted with the 9 months showing for the corresponding period last season. The consumption of oil by months with a comparison, follows:

	1922-23 Bbl	1921-22 Bbl
August	168,000	260 000
September	234,000	280,000
October	298,000	234,000
November	273,500	174,000
December	190,000	128,000
January	233,000	192,000
February	192,250	208,000
March..	167,000	204,000
April..	151,250	110,000
Totals ..	1,907,000	1,790,000

Average monthly consumption of cottonseed oil for the first 9 months of the crop year was 212,000 bbl., against 199,000 bbl. a year ago.

The cotton crop year begins with Aug. 1, but seed does not commence to move in volume before September and it takes another month to convert the seed into available oil. In other words, new crop oil will not come on the market in a large way before October and old crop material will have to fill in the gap between Aug. 1 and the time when the new crop production is actually available. At the close of the 1921-22 season the stocks on hand were estimated at 434,325 bbl., the monthly consumption of cottonseed oil for the last 3 months of the crop year amounting to 155,542 bbl. Later developments in the market proved conclusively that the carry-over was inadequate and a sharp uplift in prices resulted.

Seed Receipts Fall Off

Seed receipts have fallen off in all directions and trade authorities believe that the movement to the mills over the remainder of the season will be smaller than had been expected. Some traders go so far as to predict that not more than 52,000 bbl of oil will be made from seed that has not yet been accounted for, so that, in addition to the visible of 720,000 as indicated by the government figures as of April 30, a total of 772,000 bbl. will be available for the May-June-July period. Deducting 434,000 bbl. (last season's carry-over) from the 772,000 bbl. now in sight, the supply of cottonseed oil actually available for the next 3 months is reduced to 338,000 lb., or 112,700 bbl. for monthly distribution. Allowing for a larger crush of "invisible" seed, the result of these calculations would not change materially.

Indications now point to a larger cotton acreage for the 1923 season, but it is yet too early for the new crop to exert much of an influence upon the market. Because of the strong statistical position operators believe that new crop developments will not play so prominent a part in the cottonseed oil trade during the early summer months. Of course, it is possible that competing oils and fats will occupy a position of prominence before the new season gets under way and such development should check any sharp upturn in cottonseed oil prices. The speculative element has shown comparatively little interest in the long side of the market, while the existing short interest in old crop options has narrowed down considerably in the last month or so. At current prices for cottonseed oil export business is considered improbable.

Trade Notes

The Pacific Coast Borax Co. has announced a 10 per cent increase in wages for the employees at its plant in Bayonne, N. J.

Société Anonyme pour l'Industrie des Métaux, Lausanne, Switzerland, has taken over the aluminum and metal business of Le Mineral Société Anonyme. The latter company will continue to trade in bauxite and chemical products. C. W. Leavitt & Co., New York, are sole selling agents in the United States for both corporations.

Arthur S. Somers, of the F. L. Lavanburg Co., has been re-elected president of the Brooklyn Chamber of Commerce.

The plant of the New Jersey Chemical & Rubber Works at Hillside, N. J., was damaged by fire last week. Loss is placed between $65,000 and $75,000.

The steamship "President Wilson" arrived at San Francisco last week from Hong Kong and, included in the general cargo, there was 758 tons of china wood oil.

Alfred B. Sloan, president of the General Motors Corporation, has been elected a director of E. I. du Pont de Nemours & Co.

The next convention of the National Foreign Trade Council will be held in Boston, in May, 1924.

California petroleum production in 1922 increased 23,739,332 bbl. over that of the previous year. The gain is attributed to the rapid and intensive development of oil fields in Los Angeles and Orange Counties.

H. Mart Smith, manager of the vegetable oil department of W. R. Grace & Co., will leave today on a business trip through the Middle West.

Charles B. Street, general superintendent of Gutta Percha & Rubber, Ltd., Toronto, Canada, died at his home in that city last Tuesday.

George K. Morrow has been elected president of the American Cotton Oil Co. to succeed L. N. Hine, who will hereafter, as vice-president, devote only a portion of his time to the affairs of the company. Mr. Morrow also was elected a director.

W. M. Gimson, consulting engineer to the Kaurilite Manufacturing Co., of Auckland, New Zealand, is in New York.

Informal discussion on the prospects for trading in linseed oil options by members of the Produce Exchange attracted some attention. The movement, however, did not take on definite form. The proposition was considered some years ago, but was dropped because of lack of interest on the part of crushers. Many in the trade take the stand that an option market in linseed oil would tend to stabilize prices. Option markets in this commodity exist in London and the different Continental crushing centers.

Washington News

Tariff Commission Considers Foreign Organization

The Tariff Commission has under consideration the establishment of a permanent organization in foreign countries. Under the direction of the commission groups of experts have already been sent abroad. It is proposed that a permanent headquarters be established at some central point in Europe. Under the plan discussed experts would continue to be sent to handle special inquiries, but their activities would be co-ordinated through representatives of the commission stationed in Europe permanently.

The plans for a foreign organization, which have been discussed more or less from time to time, have been expanded considerably. It is now proposed that the foreign representatives of the commission shall make reports on industrial conditions and particularly on matters bearing on the tariff. Members of the commission desire to establish a closer contact with conditions in foreign industries regarding which information must be available in determining rates of duty under the flexible provisions of the tariff law.

Fellowships Offered by Bureau of Mines and Colleges

During the next school year, the following universities will offer graduate fellowships in mining, metallurgical and chemical research, in co-operation with the Bureau of Mines: University of Alabama, University of Arizona, Carnegie Institute of Technology, University of Missouri, Ohio State University, University of Utah and University of Washington.

This plan of fellowship first was effected through a co-operative agreement between the Bureau of Mines and the University of Utah in 1914. The results have been highly successful throughout that period. The fellowships are awarded graduates of colleges, preferably of mining schools, who have shown special aptitude for research and investigational work.

Appraisers Sustain Protest on Creolin Pearson Duty

The Board of United States General Appraisers, in an opinion sustaining protests of Merck & Co., finds that creolin pearson, containing pyridine and naphthalene, but not manufactured therefrom, was properly dutiable at 15 per cent ad valorem, either as a non-enumerated article or as a chemical compound, under paragraph 385 of the tariff act of 1913, rather than under group 3, Title V, section 500, of the act of Sept. 8, 1916, at 30 per cent ad valorem, as a coal-tar product suitable for medicinal purposes.

Refractories Standardization Looms in Steel Industries

In response to the request of prominent manufacturers and users of sleeves, nozzles and stoppers required in steel making, the division of simplified practice of the Department of Commerce called a meeting of all interests concerned on May 21. The American Foundrymen's Association had adopted six nozzles, nine sleeves and one stopper as standard at its convention on Oct 17, 1918, but these standard types and sizes have not been widely recognized throughout the steel industry, as is shown by the fact that there are now close to 300 types and sizes of these refractories on the market. This great variety complicates production, hinders efficient distribution and retards service until now both the producers and the consumers favor applying simplified practice or the elimination of the superfluous and excessive varieties and the retention of those types and sizes in proved greatest demand.

It was agreed at the conference that standardization would be advantageous to all parties and for that reason it was recommended that the Department of Commerce call a general conference of makers and users. June 18, 1923, was the day set to hold this conference in Washington.

Manufacturers of Picric Acid Subject to Tax

For the information of internal revenue officers and others concerned, C. R. Nash, acting Commissioner of Internal Revenue, has issued a statement to the effect that a person who manufactures and sells for military purposes picric acid containing 10 per cent water is a manufacturer of an explosive within the meaning of section 301, subdivision 1 (a) of the revenue act of 1916 and hence subject to the munition manufacturer's tax levied under Title III of that act.

This is issued, not as a ruling of the Treasury Department, but is in accord with a decision handed down in the United States District Court for the Southern District of New York.

Returns on New York Coal-Tar Imports Merely Approximate

The returns being made to the Department of Commerce on importations of coal-tar products at the port of New York are being compiled with the idea that the record is only approximate. The idea is to make available promptly a general idea of the volume of these imports. These returns have no value as a statistical record, it is pointed out, as the accurate figures showing imports at all ports become available a month or 6 weeks later.

Industrial Gas Section to Organize

Engineers interested in the industrial sales of city gas are planning to organize a section of the American Gas Association to deal particularly with this phase of the industry. The organization meeting will be held June 6 at the Engineering Societies Building, New York City.

During recent years the commercial branch of the gas industry has been actively represented by the Commercial Section of A.G.A. However, most of the attention of this section has necessarily been given to lighting, cooking, water heating and other domestic applications of gas and the problems of salesmanship in these fields. The engineering sales work involving design, installation and maintenance of industrial equipment for large-scale use of gas has not been as much considered, and engineers interested in those fields have been instrumental in getting authority for this new section.

Financial Notes

The Texas Gulf Sulphur Co. has declared a quarterly dividend of $1.50 a share. The company previously had been paying dividends at the rate of $5 a share per year.

Stockholders of the Lee Tire & Rubber Corporation will meet June 6 to vote on proposed increase in capital stock from 150,000 shares to 300,000 shares, no par value. It is reported that the new issue of stock will be used to purchase the Republic Rubber Co. of Youngstown, Ohio.

The United Drug Co. has declared a dividend of $1.50 on the common stock. Dividends had been passed since September, 1921, prior to which time the stock had been on an 8 per cent basis.

The Arnold Print Works has increased capital stock from $1,500,000 to $3,000,000 by addition of 15,000 shares of $100 par common to be issued as a 100 per cent stock dividend to holders of record May. 2.

The Chemical Paper Manufacturing Co. has increased its capital stock from $2,000,000 to $2,500,000.

The Pure Oil Co. is negotiating with bankers for new financing to the extent of between $8,000,000 and $10,000,000. It is understood that the financing is for the benefit of the company's subsidiary, the Humphreys Oil Co.

The Casein Co. of America has issued its annual report, which shows a surplus, after depreciation, of $407,159 for the year ended Dec. 31. This compares with a deficit of $82,175 for the year preceding.

Voting trust certificates for 402,131 shares of capital stock of the Columbian Carbon Co. have been admitted to trading on the New York Stock Exchange.

Ultramarine Plant Started

The National Ultramarine Co., organized by a group of West Virginia business men, will erect a $200,000 plant at Cincinnati, Ohio. It is announced that this company is to promote the invention of Ralph Baugher of Huntington, W. Va., in the manufacture of its product. The details of this method have not been disclosed.

Ultramarine blue is considerably used as a pigment in inks, in wallpaper whitening and in bringing food products such as sugar and flour to color.

Exposition Plans Course in Chemical Engineering

Exhibits as Planned Indicate an Extremely Interesting Show in September

Students of chemistry and chemical engineering who attend the Ninth National Exposition of Chemical Industries are to have an unusual opportunity to study the exhibits. Group conferences and a series of lectures have been planned. This short practical course to be given in connection with the 1923 exposition will be under the guidance of a number of the industry's biggest men, and will be without cost to the students. It will include plant equipment in disintegrating, mechanical separation and grading, thickening, filtration, and separation by centrifugals, evaporation, distillation, drying and the general handling of materials. The "why, when and where" of construction materials will also be given attention. Chemical distribution in commerce will be the third phase. Students desiring to attend and instructors wishing to enroll classes are required to file applications with the exposition management at the Grand Central Palace, New York, before the closing of colleges this year. Accommodations for students during their stay in New York will be arranged at Columbia University dormitories.

Preliminary Exhibition Plans

An endeavor is being made to have the exposition more complete this year than ever before. A consolidated dyestuff exhibit of a very elaborate nature, furnished by a number of the leading American manufacturers, has been planned. Dye for everything from the rug on the floor to the paper on the ceiling, including the apparel of the occupants, will be shown in a new way. The actual production of furfural from corncobs, a completely equipped modern chemical laboratory alongside of an ancient alchemist's shop, chemical warfare in operation, and other novel exhibits have been listed among the preliminary plans. The educational exhibits of the exposition, already taking shape under the direction of Major H. S. Kimberly, who was recently selected by the advisory committee for this work, will cover a broad field and aim to show the human relation, breadth and importance of the chemical industry, particularly its developments since the war, to the American business man and the public. To sell the idea of America's self-sufficiency in chemicals, dyes, chemical machinery and equipment, and complete independence from Europe, is being made the basis for the entire educational scope of the Ninth Chemical Exposition when it is held during the week of Sept. 17 to 22 at Grand Central Palace, New York.

Treasury Department Issues Instructions on Currency Conversion

Determines Necessity for Consular Invoices—Collectors' Also Instructed to Make Allowance for Shortages in Delivery

THE Treasury Department has issued instructions to customs collectors regarding the conversion of currency for the purpose of determining the necessity for consular invoices in making export shipments from foreign markets. The opinion as expressed by the Assistant Secretary of the Treasury is that if the proclaimed value of foreign currency in which the foreign value or the export value of the merchandise is expressed varies by less than 5 per cent from a value measured by the buying rate in the New York market at noon on the day of exportation, conversion must be made at the proclaimed value. This, it was stated, follows the provisions of section 522 of the Fordney-McCumber tariff act and if the result of such conversion exceed $100, a consular invoice is necessary. Under section 482 of the tariff act consular invoices are required for goods exceeding $100 in value.

If, however, the decision continues, the value of the foreign currency has not been proclaimed, or if the proclaimed value varies by 5 per cent or more from a value measured by the buying rate in the New York market at noon on the day of exportation, conversion shall be made at the rate certified by the Federal Reserve Bank of New York, also following the provisions of section 522, and if the result of such conversion exceeds $100, a consular invoice is necessary.

Another important decision was rendered by the Treasury Department. It had reference to an allowance in assessing duties, in cases where the delivery of goods to the consignee showed that a shortage existed, as compared with the quantity shown on the shipping documents. The decision was made as a result of a finding on the part of the Court of Customs Appeals and directs collectors to follow the rule laid down in the courts' decision that the collector shall make allowance in the absence of fraud for any deficiency reported to him by the appraiser when the merchandise has at all times been in the uninterrupted possession of the government, notwithstanding that the deficiency is due to robbery occurring after importation. The decision was handed down in the case of McKesson & Robbins and held that section 2991 of the Revised Statutes is unambiguous and mandatory in the requirement that the collector shall make the allowance mentioned for shortages.

The rule affects enforcement of the concluding provision of section 499 of the Fordney-McCumber tariff act and the first paragraph of article 608 of the Customs Regulations is amended to read as follows:

"Allowance shall be made in the liquidation of duties for deficiencies in packages found by the appraiser or other customs officer and so certified to the collector."

The second paragraph of article 608, as amended by T. D. 37813 has in consequence been amended by striking out the word "two" and substituting the word "five," thus extending the time within which applications may be filed for allowance in duties on account of shortage in an unexamined case.

Investigate Foreign Control of Crude Rubber

Plans for investigating the crude rubber situation, especially with reference to the monopoly of the industry as now held by foreign countries, have now been well advanced. The Commerce Department will undertake this investigation and will utilize a special staff of rubber experts. The latter will visit primary sources of supply and will make a study of the best methods of production with a view to developing possible American controlled sources of supply.

Lehigh Tests to Develop Metal Strain Measure

Stretching a metal until it squeaks and listening for the squeak with a microphone will give a test showing how much strain that metal can stand as a girder or as a rail, according to experiments conducted in the physics department of Lehigh University.

These experiments may develop a novel method for finding quickly and accurately the elastic limit of metals. By this method all forgings may be rapidly tested before they are put into use. Several kinds of metals have been successfully tested in the Lehigh laboratory.

It was found that squeaking, rasping sounds were produced after the pull had reached a certain definite value, and this value was different for the different metals used. The tests indicated that the sounds, caused by grating of the molecules, were not produced until the elastic limit of the material had been reached. The work is likely to be continued with more refined apparatus in the Lehigh physics laboratory.

Tariff Commission Considers Foreign Organization

The Tariff Commission has under consideration the establishment of a permanent organization in foreign countries. Under the direction of the commission groups of experts have already been sent abroad. It is proposed that a permanent headquarters be established at some central point in Europe. Under the plan discussed experts would continue to be sent to handle special inquiries, but their activities would be co-ordinated through representatives of the commission stationed in Europe permanently.

The plans for a foreign organization, which have been discussed more or less from time to time, have been expanded considerably. It is now proposed that the foreign representatives of the commission shall make reports on industrial conditions and particularly on matters bearing on the tariff. Members of the commission desire to establish a closer contact with conditions in foreign industries regarding which information must be available in determining rates of duty under the flexible provisions of the tariff law.

Fellowships Offered by Bureau of Mines and Colleges

During the next school year, the following universities will offer graduate fellowships in mining, metallurgical and chemical research, in co-operation with the Bureau of Mines: University of Alabama, University of Arizona, Carnegie Institute of Technology, University of Missouri, Ohio State University, University of Utah and University of Washington.

This plan of fellowship first was effected through a co-operative agreement between the Bureau of Mines and the University of Utah in 1914. The results have been highly successful throughout that period. The fellowships are awarded graduates of colleges, preferably of mining schools, who have shown special aptitude for research and investigational work.

Appraisers Sustain Protest on Creolin Pearson Duty

The Board of United States General Appraisers, in an opinion sustaining protests of Merck & Co., finds that creolin pearson, containing pyridine and naphthalene, but not manufactured therefrom, was properly dutiable at 15 per cent ad valorem, either as a non-enumerated article or as a chemical compound, under paragraph 385 of the tariff act of 1913, rather than under group 3, Title V, section 500, of the act of Sept. 8, 1916, at 30 per cent ad valorem, as a coal-tar product suitable for medicinal purposes.

Refractories Standardization Looms in Steel Industries

In response to the request of prominent manufacturers and users of sleeves, nozzles and stoppers required in steel making, the division of simplified practice of the Department of Commerce called a meeting of all interests concerned on May 21. The American Foundrymen's Association had adopted six nozzles, nine sleeves and one stopper as standard at its convention on Oct 17, 1918, but these standard types and sizes have not been widely recognized throughout the steel industry, as is shown by the fact that there are now close to 300 types and sizes of these refractories on the market. This great variety complicates production, hinders efficient distribution and retards service until now both the producers and the consumers favor applying simplified practice or the elimination of the superfluous and excessive varieties and the retention of those types and sizes in proved greatest demand.

It was agreed at the conference that standardization would be advantageous to all parties and for that reason it was recommended that the Department of Commerce call a general conference of makers and users. June 18, 1923, was the day set to hold this conference in Washington.

Manufacturers of Picric Acid Subject to Tax

For the information of internal revenue officers and others concerned, C. R. Nash, acting Commissioner of Internal Revenue, has issued a statement to the effect that a person who manufactures and sells for military purposes picric acid containing 10 per cent water is a manufacturer of an explosive within the meaning of section 301, subdivision 1 (*a*) of the revenue act of 1916 and hence subject to the munition manufacturer's tax levied under Title III of that act.

This is issued, not as a ruling of the Treasury Department, but is in accord with a decision handed down in the United States District Court for the Southern District of New York.

Returns on New York Coal-Tar Imports Merely Approximate

The returns being made to the Department of Commerce on importations of coal-tar products at the port of New York are being compiled with the idea that the record is only approximate. The idea is to make available promptly a general idea of the volume of these imports. These returns have no value as a statistical record, it is pointed out, as the accurate figures showing imports at all ports become available a month or 6 weeks later.

Industrial Gas Section to Organize

Engineers interested in the industrial sales of city gas are planning to organize a section of the American Gas Association to deal particularly with this phase of the industry. The organization meeting will be held June 6 at the Engineering Societies Building, New York City.

During recent years the commercial branch of the gas industry has been actively represented by the Commercial Section of A.G.A. However, most of the attention of this section has necessarily been given to lighting, cooking, water heating and other domestic applications of gas and the problems of salesmanship in these fields. The engineering sales work involving design, installation and maintenance of industrial equipment for large-scale use of gas has not been as much considered, and engineers interested in those fields have been instrumental in getting authority for this new section.

Financial Notes

The Texas Gulf Sulphur Co. has declared a quarterly dividend of $1.50 a share. The company previously had been paying dividends at the rate of $5 a share per year.

Stockholders of the Lee Tire & Rubber Corporation will meet June 6 to vote on proposed increase in capital stock from 150,000 shares to 300,000 shares, no par value. It is reported that the new issue of stock will be used to purchase the Republic Rubber Co. of Youngstown, Ohio.

The United Drug Co. has declared a dividend of $1.50 on the common stock. Dividends had been passed since September, 1921, prior to which time the stock had been on an 8 per cent basis.

The Arnold Print Works has increased capital stock from $1,500,000 to $3,000,000 by addition of 15,000 shares of $100 par common to be issued as a 100 per cent stock dividend to holders of record May. 2.

The Chemical Paper Manufacturing Co. has increased its capital stock from $2,000,000 to $2,500,000.

The Pure Oil Co. is negotiating with bankers for new financing to the extent of between $8,000,000 and $10,000,000. It is understood that the financing is for the benefit of the company's subsidiary, the Humphreys Oil Co.

The Casein Co. of America has issued its annual report, which shows a surplus, after depreciation, of $407,159 for the year ended Dec. 31. This compares with a deficit of $82,175 for the year preceding.

Voting trust certificates for 402,131 shares of capital stock of the Columbian Carbon Co. have been admitted to trading on the New York Stock Exchange.

Hydrated 80-85 per cent was quiet with the general asking price at 7¾c. per lb. but on firm business it was stated that 7½c. per lb. could be done.

Chlorate of Potash—Heavy arrivals of German chlorate reached the market during the week. Sellers reported prices unchanged but there was an easier undertone and buyers did not appear to have much confidence in the quoted values. The quotation is 7½c. per lb. Domestic makes are held at 8½c. per lb., works.

Permanganate of Potash—The spot market is openly quoted at 18½c. per lb. with only moderate interest shown by buyers. The shipment market has been unsettled by the withdrawal of bids by importers and prices c.i.f. New York have been reduced in order to induce buying. Many sellers stated that there was no fixed price for nearby shipments but it was intimated that holders abroad would consider bids around 17c per lb.

Prussiate of Potash—Resale lots of yellow prussiate have been offered regularly and have had a disturbing effect on prices. Sales are said to have gone through at 36c. per lb. with 36½c. per lb. asked in different quarters. On shipments as low as 35c. per lb. has been heard. Red prussiate is inactive and it is a buyers' market with values variously reported from 65c. to 70c per lb.

Sodas

Soda Ash—There is an irregular demand for moderate sized quantities on new accounts but the greater part of the activity of the market is concerned with deliveries against contracts. Price changes are infrequent and prominent factors continue to quote light ash at 1.20c. per lb. in single bags, carlots, at works. Light ash in barrels is held at 1.40c. per lb., works. Dense ash is offered at 1.25c. per lb. in bags at works, basis 48 per cent. In the spot market light ash is quoted at 1.75c. per lb. in single bags and 1.95 per lb. in barrels.

Bichromate of Soda—The firm position of bichromate has continued through the week. Some large producers are reported to have sold large amounts prior to recent advances in price. With producing costs rising they did not care to take on further orders for large lots at the lower price level. Consequently they marked up prices and other producers followed suit. For the time being, at least, competition among sellers is not not keen and reports that current values are based on producing costs, are generally credited. Asking prices are 8½c. per lb., works, and upward on a quantity basis.

Caustic Soda—No improvement in export demand has been shown and though most sellers are quoting at unchanged price levels, the market can hardly be described as firm. In some quarters there is a disposition to hold the f.a.s. quotation for standard brands at 3.40c. per lb. but this figure is too high to interest buyers and 3.35c. per lb. is more representative of the market with the possibility of doing 3.30c. per lb. on outside brands. There is a steady withdrawal on contracts to domestic consumers with 2½c. per lb., carlots, works, quoted for basis 60 per cent. The spot market is steady at 3½c. per lb., flat for round lots.

Nitrate of Soda—Arrivals from primary points have brought out some selling pressure and reports were heard that spot material sold at $2.52½ per 100 lb. Stocks at southern points also are reported to be large and some resale material is reported to have changed hands as low as $2.40 per 100 lb. For June delivery local sellers were asking $2.57½ per 100 lb. For July forward the schedule as recently adopted was in effect with prices ranging from $2.45 to $2.60 per 100 lb. according to time of delivery. A report from Europe states that German synthetic nitrate is in supply barely sufficient for requirements in that country. The report further states that stocks of nitrate of soda in the United Kingdom held on speculative account have been liquidated and prices have firmed up. Production in Chile has not been curtailed to any extent as yet but exports for April exceeded production.

Prussiate of Soda—Slow demand and free offerings have added to the weakness of prices and buyers have been able to take on stocks at greater advantage during the past week. Spot material has been offered at 16¼c. per lb. without arousing any sustained interest from buyers. For June delivery there were sellers at 16c. per lb. and this included some prominent domestic producers.

Miscellaneous Chemicals

Arsenic — Very little change was noted in market during the week. Buyers are watching closely but are buying only when prices are made attractive. Arrivals from foreign markets are coming in regularly. Moreover stocks are held by numerous sellers and this makes consumers cautious about placing orders. The spot market was dull at 14¾@15c. per lb. It is possible that the inside figures could be shaded but for the most part holders are not pressing matters. Domestic producers are quoting 13½c. per lb. for prompt and 12c. per lb. for June-July. For the second half of the year they quote 11c. per lb.

Alum—Domestic makers of ammonia alum are holding prices on a steady basis with buying described as moderate. Lump is held at 3.50@3.60c. per lb. Chrome alum has responded to higher producing costs and the inside figure is now placed at 5¾c. per lb. Imported potash alum was quiet and easy in tone with quotations at 3@3¼c. per lb. for lump.

Calcium Arsenate—Demand is proving disappointing. Dealers and distributors placed orders some time ago but in many cases they have not yet taken April deliveries. Stocks are fairly large and it is a question whether selling pressure or buying demand will first assert itself. Prices are generally quoted at 17c. per lb. but some sellers admit they are open to bids and at present it is a buyers' market with 16c. per lb. as a figure at which business might be done.

Copper Sulphate—Leading makers continue to quote the market at 6c. per lb. on the large crystals and 5.90c. per lb. on the small. It was reported that smaller operators in domestic goods took on business down to 5.75c. per lb. Imported material was easier and prices heard during the week ranged from 5½@5¾c. per lb. immediate delivery. Stocks of foreign material were considered large. According to some reports Canadian buyers took on several lots of imported sulphate. The shipment quotation on German goods settled around 5¾c. per lb.

Epsom Salt—Several large parcels arrived from German ports, but, according to dealers, nearly all of this material will go into firm hands. The market settled at 90c.@$1.00 per 100 pounds.

Nickel Salts—There were transactions in less than carload lots on the former basis of 10½c. on the double and 11½c. on the single, in barrels.

Tin Oxide—The market eased off on the recent decline in the metal. The quotation was cut 2c. per lb., establishing the market on the 48c. per lb. basis. Demand was quiet all week. A slightly higher market for the metal set in just before the close and this seemed to steady prices for the oxide.

Sal Ammoniac—Pressure to sell imported material was in evidence and lower prices were named in more than one direction. The white granular, imported, in casks, closed nominally at 6½@6¾c. per lb., immediate delivery. Domestic held at 7½@7¾c. per lb. On the gray domestic the offerings were moderate and prices held at 8@8½c. per lb., f.o.b. point of production.

Sulphate of Ammonia—Contract business has made its appearance in fair volume and considerable business has been booked in the past two weeks. The prices quoted are on a basis of $3 for delivery at northern points and $3.15 for delivery in the south. The spot price is given at $3.25 per 100 lb. for bulk lots and f.a.s. quotations are $3.60 @$3.65 per 100 lb.

Alcohol

No additional price changes were reported by first-hands. The advance in denatured was maintained, although scattered parcels of imported material might have been picked up at concessions. The special, No. 1 formula, closed at 35c. per gal., in drums, and 41c. per gal., in bbl., carload basis. Completely denatured, formula No. 1, 188 proof, was offered by leading interests at 43c. per gal., in drums, and 49c. per gal., in bbl. Demand for denatured was quiet. Ethyl spirits, 190 proof, U. S. P., closed unchanged at $4.70 per gal. Methanol also was unaltered in price, producers asking $1.18 per gal. on the 95 per cent grade.

Coal-Tar Products

Naphthalene Imports Increase; Prices on Spot Easier—Cresylic Acid Lower—Phenol Unsettled—Salicylates Irregular

THE market for naphthalene was easier in nearly all directions. Trading was inactive and with foreign offerings lower some shading of spot prices was apparent. The importations of crude material again assumed large proportions, the bulk of the naphthalene arriving coming from Rotterdam. Intermediate makers appear to be stocked up for the time being and no new business of consequence went through.

One of the largest producers of salicylic acid reduced prices to the extent of 5c. per lb., due, no doubt, to the keen competition in the salicylates. This reduction narrowed the range of prices so that leading factors were only 5c. apart instead of 10c. Demand for the salicylates showed no improvement. Phenol on spot in outside channels was unsettled, but no radical change in prices occurred. A feature was the decline in cresylic acid, spot prices on the imported closing about 5c. per gal. lower. Domestic makers reported the market on cresylic as nominally unchanged.

Benzol demand was described as fair in some quarters, while other operators said that they could not interest buyers. The offerings of zylene on spot were scanty and firm prices prevailed in all quarters.

Aniline Oil—Producers reported a steady market notwithstanding the routine nature of business. Prices held at 16c. per lb. in drums, carlots, immediate and nearby delivery.

Aniline Salt—There were offerings of aniline salt at 23c. per lb., immediate shipment. The market was barely steady in some quarters.

Benzaldehyde—There was a fair inquiry for benzaldehyde, and leading producers continued to quote firm at 75@80c. per lb. on the technical grade, drums included.

Benzylchloride—Production is limited and spot prices were wholly nominal. On nearby material there were offerings at 30c. on the technical grade and 45c. on the 95@97 per cent refined.

Beta Naphthol—There were offerings of the technical grade on spot at 22c. per lb., indicating that first hands were no longer so firm in their ideas.

Benzene—The demand was restricted to the motor grades, according to first hands, and production of pure benzene was limited to actual requirements only. As a result of this policy prices for the pure were maintained on the 30c. basis in spite of the positive nature of business. The 90 per cent grade held nominally at 27c. per gal. tank-car basis.

Cresylic Acid—Offerings of spot material of foreign make were freer and prices again softened. There were sellers of the 97 per cent grade at $1.20 per gal. On the 95 per cent, dark, a price of $1.10 per gal. was named here. Domestic producers say that their output is sold ahead and refused to name a flat quotation.

Naphthalene — Importations were large, and with cables on crude easier, prices at the close were unsettled. Crude to import settled at 3⅝@3¾c. per lb. Flake on spot sold at 8¾c., a decline of ¼c. from the trading level of the week previous. On ball the market held around 9½@9¾c. per lb.

Phenol—One small parcel sold on spot at 49c. per lb., but additional offerings at this figure did not come out. In a general way the asking prices at the close ranged from 52@54c. per lb. for spot goods, which compares with 54@55c. per lb. a week ago. Demand was inactive and the undertone on resale material was barely steady. Producers report a sold up condition so far as they are concerned. Deliveries against contract are moving at 27@28c. per lb.

Salicylic Acid—One factor, who previously held out for 50c. on the U.S.P. grade, lowered his views to 45c. during the past week. In several other quarters the U.S.P. grade was offered at 40c. per lb. The demand was quiet, the recent exhibition of price cutting being too fresh in the minds of prospective buyers.

Paranitraniline—Producers held out for 75c. per lb., but in some quarters it was possible to pick up supplies at concessions. Second hands reported scattered business at 70@72c. per lb.

Solvent Naphtha—Demand was not so active and there were offerings on the basis of 27c. per gal. in tanks for the waterwhite immediate shipment from works.

Belgian Hand-Made Window Glass Production Declines

A report from Vice-Consul Schuler at Brussels states the manufacture of window glass in Belgium is undergoing a change, with the factories discarding the hand-making process for machines.

Factories now operating with Fourcault glass-making machines are operating at Dampremy and Montignies, while several plants at Roux are putting in glass-making machines. A new window glass-making plant which is also to use Fourcault machines is to be established at Zeebrugge. Glass manufacturers at Dampremy are interested in this proposed factory.

Another mechanical glass-making plant, that of Libbey Owens, in which American and Belgian capital is interested, has begun operation. This factory, work on which was started in 1921, is nearly finished. It will have a daily production of 40,000 sq.m. of glass.

Annual Coal-Tar Census to Be Issued in June

All data for the annual census of coal-tar dyes and chemicals and synthetic organic chemicals from other than a coal-tar base have been received by the Tariff Commission. The work of compilation will be started immediately under the direction of W. N. Watson, color specialist and acting chief of the chemical section, and it is hoped to issue the report some time before the end of June.

The census will present statistics on domestic production and on importations during 1922, arranged so the figures may be interpreted readily.

George Rossen to Head Produce Exchange

The annual election of officers to the New York Produce Exchange will be held on June 4. George Rossen has been nominated for president, P. H. Holt, vice-president and Edward R. Carhart, treasurer. W. A. Johns, L. W. Forbell, B. H. Wunder, W. W. Starr, Winchester Noyes and William Beatty are on the regular ticket as managers to serve for a period of 2 years.

Vegetable Oils and Fats

Cottonseed Steady on Light Offerings—Linseed Dull and Irregular in Forward Positions—Tallow Firmer

TRADING in vegetable oils was inactive, yet prices did not change much one way or the other. Cottonseed, both crude and refined, reflected the tight statistical situation and a feature during the week was the strength in the May option. New crop developments failed to exert much of an influence on the market. Arrivals of Argentine flaxseed were heavy, and with new business in oil disappointing it appears more than likely that the shortage in the supply available for immediate shipment will soon be a thing of the past. Coconut was unsettled on reports of lower prices on the coast. China wood was dull and prices named were wholly nominal. Soya bean oil was unchanged. Crude corn sold off in the west. Palm oils were easy early in the week on the drop in tallow, but steadied later. Tallow sold as low as 7¼c. ex-plant on the recent slump.

Linseed — Several crushers entertained firmer views on early June business, but in the absence of any imported trading, and with foreign oil available at concessions, the market favored buyers throughout the week. Spot and first half of June delivery closed at $1.13@$1.14 per gal., in cooperage, carload lots. On late June business prices ranged from $1.11@$1.12 per gal., while July forward held at $1.03@$1.04 per gal., carload lots, cooperage basis. The demand for futures was dull and crushers admitted that no real effort has been made for some time past to really sound the market on distant deliveries. Imported linseed oil was offered for immediate delivery at $1.05@$1.07 per gal., in bbl., duty paid. Duluth seed was easier at one time, but reports of frost in the flax belt steadied prices before the close. The planting season for all grains is late and this may result in a larger acreage to flax than was first predicted. With planting still under way it is too soon for any estimates on the acreage. Argentine offerings increased and the June option at Buenos Aires went down to $1.91½. Exports from the Argentine to all countries since the first of the year amounted to more than 31,000,000 bushels. Indian shipments for the past week amounted to 400,000 bushels consigned to the United Kingdom and 32,000 bushels consigned to the Continent. Export demand for cake in the New York market was quiet with prices nominal at $34@$35 per ton.

Cottonseed—In the option market for refined oil the feature was the strength in the May position. Shorts were buyers in a narrow market and with lard firmer prices showed moderate gains. Cash business was fair for this season of the year and generally operators felt that business will continue at a pace sufficient to exhaust the old crop offerings, especially if prices do not advance out of all proportion to the intrinsic value of the commodity. The statistical situation, reviewed elsewhere in this issue, is said to be the strongest in years. Crude oil offerings in the south were light and holders refused to quote less than 10c. per lb., buyers' tanks, f.o.b. mills, southeast and valley. In Texas scattered lots sold at 9¾c., f.o.b. mills. Bleachable oil was advanced ¼c., the market closing at 10⅝c. per lb., buyers' tanks, f.o.b. Texas common points. Consumption of oil during April amounted to 151,233 barrels, which compares with 167,000 bbl. in March and 110,000 bbl. in April a year ago. The April showing was better than expected, especially in view of the lower market for lard. Lard compound held at 12¾@13¼c. per lb.

China Wood Oil—Demand was lacking and prices were unsettled in all directions. Several round-lots arrived here last week, but most of this oil had been sold on contract. Spot oil settled at 28c. asked, with nearby at 25c. and futures at 23c. On Oct.-Nov.-Dec. business 21c. could have been done.

Coconut Oil—Offerings were liberal and prices again were unsettled. It was reported that a large soaper took on a long time contract at 8¼c. for Ceylon type oil, sellers' tanks, delivered. Spot and nearby Ceylon type oil closed at 8⅞c. asked, sellers' tanks, New York. On the Pacific coast nominal prices ranged from 8@8¼c., sellers' tanks, May-June-July shipment. Manila oil in bulk settled at 7¾@7⅞c., c.i.f. coast ports.

Corn Oil—Several cars of crude oil sold at 9¼c., f.o.b. point of production, a decline of ¼c. for the week.

Olive Oil Foots—Prime green foots were offered at 9@9¼c. per lb., spot New York, while on ex-dock material it was intimated that 9c. could have been shaded. The market was quiet.

Palm Oil—Lagos ex-dock was offered at 7¼c. at one time. No important business resulted. Niger settled at 7@7¼c., as to position and seller. Towards the close prices steadied a little on the recovery in tallow.

Menhaden Oil—The fishing will commence this week. Reports from several of the fish factories indicate that operators are experiencing difficulty in securing labor at reasonable wages and it is probable that the entire fleet may not be able to participate. This kind of talk tends to support oil prices in the face of quiet trading conditions. Crude menhaden oil was held at 50c., tank cars, works, forward delivery.

Tallow and Greases—The lowest trading basis for extra tallow was reached about a week ago when one lot sold at 7¼c. per lb., ex-plant. Later some export buying set in and this steadied the market. Late last week 7½c. ex-plant was paid for a round-lot, Oleo stearine sold down to 9c. per lb., 5 cars changing hands at this price. No. 1 oleo oil sold at 13⅝c. Yellow grease closed at 6¾@7c. per lb.

Miscellaneous Materials

Casein—Importations were heavy and this was reflected in irregular prices for spot material. At the close the lower grades were available at 19½@22½c. per lb.

Glycerine—There were offerings of C. P. glycerine by producers not so well established in this market at concessions which seemed to unsettle prices. Leading refiners offered C. P. at 17c. in drums, which compares with 17½c. a week ago. During the week outside goods sold down to 16½c. Dynamite was wholly nominal in the absence of demand of consequence and scattered lots might have been picked up for less than 16c. per lb., carload basis. The crude held relatively steady and 11c. appeared to be the inside trading level on domestic soap-lye, 80 per cent, loose, carload lots, but no sales were reported. Arrivals of foreign crude attracted some attention and, according to reports, refiners have been steady buyers of imported goods.

Naval Stores—The market for turpentine eased off again in sympathy with lower selling ideas in the south. There were offerings here at $1.11@$1.15 per gal. and prices at the close were very unsettled. Advices from the south revealed larger receipts, with only scattered buying. Export trade was slow in all directions. Rosins also developed weakness and final prices were from 5@10c. per bbl. lower. The "B" grade settled at $5.85@$5.90 per bbl.

Shellac — Cables from Calcutta reported an unsettled market and operators here appeared anxious to liquidate. T. N. on spot sold at 60@62c. per lb., which compares with 62@63c. per lb. a week ago. Bleached, bonedry, was lowered to 73c. on spot. Superfine orange settled at 66c., with the ordinary at 63@64c. per lb.

Varnish Gums—Batavian damar was in larger supply and quotations were revised downwards to 28@28½c. On futures prices ranged from 27½@27¾c. per lb. Demand was quiet.

White Lead—There was a steadier market for the metal, but leading interests continued to offer pig lead at 7½c., New York. Standard dry white lead was in good demand and corroders maintained prices on the basis of 9¾c. per lb., in casks, carload lots. Other lead products also closed the week unchanged. The undertone, however, was barely steady.

Zinc Oxide—New business was not so much in evidence, but deliveries against old contracts were sufficient to take care of production and everything considered the market presented a steady appearance. Leading producers held out for 8c. on the American process, lead free. Red seal, French process, was unchanged at 9¾c. per lb.

Imports at the Port of New York

May 18 to May 24

Badcock & Co ; 160 csk , St. Johns, Nat'l Oil Products Co.; 200 bbl , Kobe, Cook & Swan Co. **Linseed**—50 bbl., London, Order , 173 bbl., Antwerp, Fontana Bros ; 288 bbl , Rotterdam, L & E. Frenkel , 80 bbl., Rotterdam, W. Benkert & Co.; 144 bbl., Rotterdam, Lockwood & Co., 318 bbl., Rotterdam, J. D. Lewis ; 145 bbl., Rotterdam, Meteor Products Co ; 583 bbl , Rotterdam, Order ; 140 bbl , Rotterdam, Elbert & Co **Olive Foots** (sulphur oil)—100 bbl., Palermo, Order ; 100 bbl., Catania, Order ; 100 bbl., Bari, Brown Bros. & Co. ; 100 bbl , Bari, Banco Comm Ital.; 600 bbl., Bari, Irving Bank-Col Trust Co.; 800 bbl., Bari, Nat'l City Bank ; 100 bbl., Bari, Order , 300 bbl , Seville, W. R Grace & Co.; 500 bbl , Seville, Deevsnap & Co **Olive** (denatured)—175 bbl., Bari, Nat'l City Bank. **Palm**—159 csk , Lagos, J. Holt & Co.; 1,402 csk., Liverpool, D. Bacon ; 160 csk., Liverpool, Nat'l City Bank ; 17 csk , Liverpool, African & Eastern Trading Co ; 467 csk , Liverpool, Nat'l Bank of Commerce ; 84 csk., Liverpool, Order ; 289 csk , Hamburg, African & Eastern Trading Corp.; 86 csk., Hamburg, Order. **Rapeseed**—256 bbl , Liverpool, Vacuum Oil Co. **Whale**—150 bbl., Hamburg, Order **Peanut**—15 bbl , Antwerp, Hummel & Co. **Perilla**—625 bbl., Dairen, Cook & Swan Co ; 300 bbl., Dairen, Balfour-Williamson & Co.; 500 bbl., Kobe, Balfour-Williamson, & Co.; 1,280 bbl., Kobe, Cook & Swan Co.

OIL SEEDS — Castor — 27,320 bg., Cocanada, Order. **Linseed**—72,951 bg., St. Lucia, Bank of the Manhattan Co , 42,634 bg., Ibicuy, Am. Linseed Co.; 47,992 bg. and 2,634,373 kilos in bulk, Montevideo, Order , 18,020 bg and 1,932,035 kilos in bulk, Rosario, Spencer Kellogg & Sons; 105,145 bg Rosario, Order , 48,963 bg. and 2,602 tons in bulk, Rosario, Order ; 8,413 bg., Buenos Aires, L. Dreyfus & Co., 33,413 bg., Buenos Aires, Order

POTASSIUM SALTS—38 csk. red prussiate, Hamburg, E Suter & Co , 1,000 csk chlorate, Hamburg, A J. Marcus, Inc.; 135 dr. permanganate, Hamburg, Order , 62 bbl caustic, Hamburg, Order , 4,000 bg sulphate, Bremen, Potash Import Corp., 20 bbl perchlorate, Swansea, Order , 18 bbl. hydrate, Hamburg, A J Marcus, Inc.; 6,000 csk. chlorate, Hamburg, Order , 6 dr salts, London, Mager, Sonderburg Co., 40 cs. caustic, Gothenburg, Mallinckrodt Chem. Works , 500 csk. chlorate, Marseilles, C. W Campbell & Co , 500 csk chlorate, Marseilles, Asia Banking Corp , 100 cs. perchlorate, Marseilles, Order.

PYRITES—7,815,810 kilos, Huelva, Pyrites Co

QUEBRACHO—1,024 bg, Buenos Aires, Order.

QUICKSILVER—11 fl., Tampico, I. Elizondo , 400 fl , Seville, Hurlsking & Co , 300 fl , Seville, H W Peabody & Co., 1,000 fl , Alicante, Order.

SAL AMMONIAC 87 csk , Hamburg Meteor Products Co , 20 csk. and 10 bbl , Bristol, C de P Field.

SHELLAC 18 cs. garnet, Hamburg, A Murphy & Co , 35 bg , Hamburg, Kaschner-Chatfield Shellac Co , 100 cs , London, London & Liverpool Bank , 100 cs , London, Order , 350 bg and 1,050 bg refuse, Calcutta, Bank of the Manhattan Co , 150 bg , Calcutta, Brown Bros & Co , 625 bg , Calcutta, Chase Nat'l Bank , 722 bg and 211 bg button, Calcutta, Order , 115 cs. sticklac, Bangkok, Order , 100 bg., Calcutta, Brown Bros & Co , 450 bg , Calcutta, First Nat'l Bank of Boston , 300 bg , Calcutta, London & Brazil Bank , 50 bg. Calcutta, Br. Bank of West Africa ; 100 bg , Calcutta, N. Y Trust Co ; 255 bg. Calcutta, Standard Bank of S A , 150 pkg , Calcutta, Iwai, Ltd ; 1,256 bg., Calcutta, Order , 25 bg. garnet lac, Hamburg, Order

SODIUM SALTS—40 cs bromide, Hamburg, R. W. Greeff & Co ; 130 bg silicate, Danzig, Hardy & Ruperti , 100 dr sulphite, Bristol, R F. Downing & Co , 336 cs cyanide, Havre, Nat'l City Bank , 24 csk. prussiate, Liverpool, H J. Baker & Bros., 28,067 bg. nitrate, Antofagasta, W R Grace & Co ; 10,885 bg. nitrate, Iquique, W R Grace & Co ; 120 dr. sulphite, Bristol, R F. Downing & Co.; 17 csk. prussiate, Rotterdam, Order , 336 cs cyanide, Marseilles, Nat'l City Bank; 137 csk. hyposulphite, Marseilles, Order.

STARCH — 500 bg potato, Rotterdam, Twenesche Bank ; 700 bg. do., Rotterdam, Stein, Hall & Co.; 1,250 bg. do., Rotterdam, Order.

SUMAC—200 bl., Palermo, Order ; 45 csk. extract, Glasgow, Am. Dyewood Co.

TALLOW—130 tc., Sydney, Nat'l City Bank ; 120 csk., Brisbane, Order ; 87 pipes, Melbourne, Order ; 100 csk , Lyttelton, Tupman, Thurlow & Co.; 298 tc., Buenos Aires, Armour & Co.

TARTAR—89 sk., Tarragona, C. Pfizer & Co.; 667 sk., Valencia, C. Pfizer & Co , 649 sk., Valencia, Royal Baking Powder Co ; 405 sk , Marseilles, Tartar Chem. Works ; 352 sk., Marseilles, C. Pfizer & Co

TURMERIC—178 bg., Cochin, Order ; 904 bg., Alleppey, Order ; 660 bg., Cochin, Order

VEGETABLE TALLOW — 500 pkg, Shanghai, Equitable Trust Co

WATTLE BARK—9,707 bl., Durban, E. J. Haley, Inc.; 1,999 bg , Durban, Bona Allen, Inc

WAXES—42 pkg. bees, Lisbon, E. A. Brummel & Co.; 212 pkg do., Lisbon, Strohmeyer & Arpe Co.; 168 pkg bees, Lisbon, Order ; 16 bg bees, Talcahuano, W. R. Grace & Co ; 88 bg. do , Talcahuano, Strohmeyer & Arpe Co ; 14 bg do , Talcahuano, Order , 84 bg do., Valparaiso, Strohmeyer & Arpe Co ; 74 bg do., Valparaiso, W. R. Grace & Co ; 40 bg bees, London, Order.

ZINC DUST—100 cs , Yokohama, Mitsui & Co.

ZINC SULPHIDE—2 csk., London, C. A. Sykes ; 6 csk., Rotterdam, E. L Bullock & Sons.

ZINC WHITE — 200 bbl., Marseilles, Reichard-Coulston, Inc ; 55 bbl., Marseilles, Order.

ZYLOL—12 dr., Rotterdam, Lunham & Moore.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 38 –	
Acetone, drums	lb	25 –	25½
Acid, acetic, 28%, bbl	100 lb.	3 38 –	3 50
Acetic, 56%, bbl	100 lb.	6 75 –	7 00
Glacial, 99½%, bbl	100 lb.	12 00 –	12 50
Boric, bbl	lb	10½–	
Citric, kegs	lb	.49 –	52
Formic, 85%	lb.	14 –	16
Gallic, tech	lb.	45 –	50
Hydrofluoric 52%, carboys	lb.	12 –	12½
Lactic, 44%, tech., light, bbl	lb.	11½–	12
22%, tech., light, bbl	lb	05½–	06
Muriatic, 18° tanks	100 lb	90 –	1 00
Muriatic, 20°, tanks,	100 lb.	1 00 –	1 10
Nitric, 36°, carboys	lb	04½–	.05
Nitric, 42°, carboys.	lb	06 –	06½
Oleum, 20%, tanks	ton	18 50 –	19 00
Oxalic, crystals, bbl	lb	13½–	.13¾
Phosphoric, 50%, carboys	lb	07½–	08½
Pyrogallic, resublimed	lb	1 50 –	1 60
Sulphuric, 60°, tanks	ton	9 50 –	11 00
Sulphuric, 60°, drums	ton	13 00 –	14 00
Sulphuric, 66°, tanks	ton	16 00	16 50
Sulphuric, 66° drums	ton	20 00 –	21 00
Tannic, U.S.P., bbl	lb	65 –	70
Tannic, tech., bbl	lb	45 –	50
Tartaric, imp., powd., bbl	lb	36½–	
Tartaric, domestic, bbl.	lb	37½–	
Tungstic, per lb	lb	1 10 –	1 20
Alcohol butyl, drums, f.o.b. works	lb	26 –	.28
Alcohol ethyl (Cologne spirit), bbl	gal	4 75 –	4 95
Ethyl 190 p'f U.S.P., bbl	gal	4 70 –	
Alcohol, methyl (see Methanol)			
Alcohol, denatured, 190 proof			
No. 1, special bbl	gal	41	
No. 1, 190 proof, special, dr	gal	35	
No. 1, 188 proof, bbl	gal	42	
No. 1, 188 proof, dr	gal	36	
No. 5, 188 proof, bbl	gal	40 –	
No. 5, 188 proof, dr	gal	34 –	
Alum, ammonia, lump, bbl	lb	03½–	03¾
Potash, lump, bbl	lb	02¾–	03¼
Chrome, lump, potash, bbl	lb.	05¼–	06
Aluminum sulphate, com., bags	100 lb	1 50 –	1.65
Iron free bags	lb	02½–	.02¾
Aqua ammonia, 26°, drums.	lb	06½–	07¾
Ammonia, anhydrous, cyl	lb	30 –	30½
Ammonium carbonate, powd casks, imported	lb	09½–	10
Ammonium carbonate, powd domestic, bbl	lb	.13 –	.14
Ammonium nitrate, tech., casks	lb	10 –	11
Amyl acetate tech., drums.	gal	3 50 –	3 75
Arsenic, white, powd., bbl	lb	14½	15
Arsenic, red, powd., kegs	lb	14¼–	14½
Barium carbonate, bbl.	ton	78 00 –	80 00
Barium chloride, bbl.	ton	85 00 –	90 00
Barium dioxide, drums	lb.	18 –	18½
Barium nitrate, casks		08 –	08½
Barium sulphate, bbl.	lb	04 –	.04½
Blanc fixe, dry, bbl	lb	04 –	.04¼
Bleaching powder, f.o.b. wks., drums	100 lb.	1 90 –	
Spot N.Y. drums	100 lb	2 40 –	
Borax, bbl	lb	05¼–	05½
Bromine, cases	lb	28 –	30
Calcium acetate, bags	100 lb	4 00 –	4 05
Calcium arsenate, dr.	lb	16½–	17
Calcium carbide, drums	lb	05½–	.05¾
Calcium chloride, fused, drums	ton	22 00 –	23.00
Gran. drums	ton	28 00 –	30 00
Calcium phosphate, mono, bbl.	lb.	06½–	07
Camphor, cases	lb.	86 –	88
Carbon bisulphide, drums	lb.	07 –	07¼
Carbon tetrachloride, drums	lb.	09½–	10
Chalk, precip.—domestic, light, bbl.	lb.	.04¼–	04½
Domestic, heavy, bbl.	lb.	03½–	03¾
Imported, light, bbl.	lb.	04½–	.05
Chlorine, liquid, tanks, wks	lb.	05½–	.05½
Cylinders, 100 lb., wks	lb.	.06 –	.06¼
Cylinders, 100 lb., spot	lb.	09 –	
Chloroform, tech., drums	lb.	35 –	.38
Cobalt oxide, bbl.	lb.	2 10 –	2.25
Copperas, bulk, f.o.b. wks.	ton	19 00 –	20 00
Copper carbonate, bbl.	lb	19 –	.20
Copper cyanide, drums.	lb.	47 –	50
Copper sulphate, dom., bbl.,	100 lb.	6.00 –	6.25
Cream of tartar, bbl	lb.	.25½–	.26½
Epsom salt, dom., tech., bbl.	100 lb.	1.90 –	2 15
Epsom salt, imp., tech., bags	100 lb.	.90 –	1.00
Epsom salt, U.S.P., dom., bbl.	100 lb.	2.50 –	2.60
Ether, U.S.P., drums	lb.	.13 –	.15
Ethyl acetate, 85%, drums	gal.	.80 –	.81
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 –	1.00

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Formaldehyde, 40%, bbl	lb	$0 14	$0 15½
Fullers earth imp., powd.	net ton	30 00	32 00
Fusel oil, ref., drums	gal	3 55	4 00
Fusel oil, crude, drums	gal	2 50	2 60
Glaubers salt, wks., bags	100 lb	1 20	1 40
Glaubers salt, imp., bags	100 lb	90	95
Glycerine, c.p., drums extra	lb	17	17½
Glycerine, dynamite, drums	lb	15½	16
Glycerine, crude 80%, loose	lb	11	11½
Iodine, resublimed	lb	4 55	4 65
Iron oxide, red, casks	lb	12	18
Lead:			
White, basic carbonate, dry, casks	lb.	09½	10
White, basic sulphate, casks	lb	09½	
White, in oil, kegs	lb	12½	14
Red, dry, casks	lb	11½	12
Red, in oil, kegs	lb	13½	15
Lead acetate, white crys., bbl	lb	14	14½
Brown, broken, casks	lb	13	13½
Lead arsenate, powd., bbl	lb	23	24
Lime-Hydrated, bbl	per ton	16 80	17 00
Lime, Lump, bbl	280 lb	3 63	3 65
Litharge, comm., casks	lb	10½	11
Lithophone, bags	lb	07	07½
in bbl	lb	07	07½
Magnesium carb., tech., bags	lb.	08	08½
Methanol, 95%, bbl	gal	1 18	1 20
Methanol, 97%, bbl	gal	1 20	1 22
Nickel salt, double, bbl.	lb.	10½	
Nickel salts, single, bbl.	lb	11½	
Phosgene		60	75
Phosphorus, red, cases	lb.	35	40
Phosphorus, yellow, cases	lb.	30	35
Potassium bichromate, casks	lb.	.11½	12
Potassium bromide, gran., bbl	lb.	.19	20
Potassium carbonate, 80-85%, calcined, casks	lb	.06½	.06¾
Potassium chlorate, powd	lb.	.07½	08
Potassium cyanide, drums	lb.	45	.50
Potassium, first sorts, cask	lb	08½	09
Potassium hydroxide (caustic potash) drums	lb.	.07½	09
Potassium iodide, cases	lb.	3.65	3 75
Potassium nitrate, bbl.	lb.	.06½	.07½
Potassium permanganate, drums	lb.	.18½	19
Potassium prussiate, red, casks	lb.	.65	67
Potassium prussiate, yellow, casks	lb.	.35½	36½
Salammoniac, white, gran., casks, imported	lb.	.06½	.07
Salammoniac, white, gran., bbl, domestic	lb.	.07½	.07¾
Gray, gran., casks	lb.	.08	.09
Salsoda, bbl.	100 lb.	1.20	1 40
Salt cake (bulk)	ton	26.00	28.00
Soda ash, light, 58%, flat, bags, contract	100 lb	1 60	1.67
Soda ash, light, basis, 48%, bags, contract, f.o.b. wks	100 lb.	1.20	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb.	1.75	1.80
Soda ash, dense, bags, contract, basis 48%	100 lb	1.17½	1.20
Soda ash, dense, in bags, resale	100 lb.	1.85	1.90
Soda, caustic, 76%, solid, drums, f.a.s.	100 lb.	3.[illegible]0	3 40
Soda, caustic, basis 60%, wks., contract	100 lb.	2 50	2 60
Soda, caustic, ground and flake, contracts	100 lb.	3.80	3 90
Soda, caustic, ground and flake, resale	100 lb.	3.72½	
Sodium acetate, works, bags	lb.	05½	06½
Sodium bicarbonate, bbl	100 lb	2.00	2 50
Sodium bichromate, casks	lb	08½	09
Sodium bisulphate (niter cake)	ton	6.00	7.00
Sodium bisulphite, powd., U.S.P., bbl.	lb.	.04½	.04¾
Sodium chlorate, kegs	lb.	.06½	.07
Sodium chloride	long ton	12.00	13 00
Sodium cyanide, cases	lb.	.20	.23
Sodium fluoride, bbl	lb.	$0.09 –	$0 10½
Sodium hyposulphite, bbl	lb	.02½–	.03
Sodium nitrite, casks	lb	.08 –	.08½
Sodium peroxide, powd., cases	lb	.28 –	.30
Sodium phosphate, dibasic, bbl	lb.	.03½–	.04
Sodium prussiate, yel. drums	lb.	.16 –	.16½
Sodium salicylic, drums	lb.	.47 –	.52
Sodium silicate (40%, drums)	100 lb.	.80 –	1.25
Sodium silicate (60%, drums)	100 lb.	2.00 –	2.25
Sodium sulphide, fused, 60-62%, drums	lb.	.04½–	.04¾
Sodium sulphite, crys., bbl.	lb.	03½–	03¾
Strontium nitrate, powd., bbl.	lb.	.12½–	13
Sulphur chloride, yel drums.	lb.	04½–	.05
Sulphur, crude	ton	18 00 –	20 00
At mine, bulk	ton	16 00 –	18.00
Sulphur, flour, bag	100 lb.	2.25 –	2.35
Sulphur, roll, bag	100 lb.	2 00 –	2.10
Sulphur dioxide, liquid, cyl.	lb	.08 –	.08½
Talc—imported, bags	ton	30 00 –	40.00
Talc—domestic powd., bags	ton	18.00 –	25.00
Tin bichloride, bbl	lb.	.12½–	.13½
Tin oxide, bbl	lb	.48 –	
Tin crystals, bbl	lb	.35½–	.36
Zinc carbonate, bags	lb.	.14 –	.14½
Zinc chloride, gran, bbl	lb	06½–	.06¾
Zinc cyanide, drums	lb.	.37 –	.38
Zinc oxide, lead free, bbl	lb.	.08 –	.08½
5% lead sulphate bags	lb.	.07½–	....
10 to 35%, lead sulphate, bags	lb	07 –	....
French, red seal, bags	lb	.09½–	......
French, green seal, bags	lb	.10½–	....
French, white seal bbl	lb	.12 –	......
Zinc sulphate, bbl.	100 lb.	2.50 –	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb	$0 65 –	$0.80
Alpha-naphthol, ref., bbl	lb	75 –	.90
Alpha-naphthylamine, bbl.	lb.	35 –	37
Aniline oil, drums	lb.	16 –	.16½
Aniline salts, bbl	lb.	23 –	24
Anthracene, 80%, drums	lb.	.75 –	1.00
Anthracene, 80%, imp., drums, duty paid	lb.	.70 –	.75
Anthraquinone, 25%, paste, drums	lb.	.70 –	.75
Benzaldehyde U.S.P., carboys	lb.	1.40 –	1.45
tech, drums	lb	75	80
Benzene, pure, water-white, tanks and drums	gal.	.30 –	.32
Benzene, 90%, tanks & drums	gal.	.27 –	.30
Benzene, 90%, drums, resale	gal.	.30 –	.33
Benzidine base, bbl.	lb.	.85 –	.90
Benzidine sulphate, bbl	lb.	.70 –	.75
Benzoic acid, U.S.P., kegs	lb	.72 –	75
Benzoate of soda, U.S.P., bbl.	lb.	.57 –	.65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 –	
Benzyl chloride, tech., drums	lb.	.30 –	.35
Beta-naphthol, tech., bbl	lb.	.22 –	.23
Beta-naphthylamine, tech	lb.	.80 –	.90
Cresol, U.S.P., drums.	lb.	.25 –	.29
Ortho-cresol, drums	lb.	.28 –	.30
Cresylic acid, 97%, resale, drums	gal.	1.20 –	..
95-97%, drums, resale	gal.	1.10 –	
Dichlorbenzene, drums	lb.	.07 –	.09
Diethylaniline, drums	lb.	.50 –	.60
Dimethylaniline, drums	lb.	.42 –	.43
Dinitrobenzene, bbl.	lb.	.19 –	.20
Dinitroclorbenzenee bbl.	lb.	.22 –	.23
Dinitronaphthalen, bbl	lb.	.30 –	.32
Dinitrophenol, bbl	lb.	.35 –	.40
Dinitrotoluene, bbl.	lb.	.20 –	.22
Dip oil, 25%, drums.	gal.	.25 –	.30
Diphenylamine, bbl.	lb.	.50 –	.52
H-acid, bbl	lb.	.80 –	.85
Meta-phenylenediamine, bbl.	lb.	1.00 –	1.05
Michlers ketone, bbl.	lb.	3.00 –	3.50
Monochlorbenzene, drums	lb.	.08 –	.10
Monoethylaniline, drums	lb.	.95 –	1.10
Naphthalene, flake, bbl.	lb.	.08½–	.09
Naphthalene, balls, bbl	lb.	.09½–	.10
Naphthionate of soda, bbl.	lb.	.58 –	.65
Naphthionic acid, crude, bbl.	lb.	.55 –	.60
Nitrobenzene, drums.	lb.	.10 –	.12
Nitro-naphthalene, bbl	lb.	.30 –	.35
Nitro-toluene, drums.	lb.	.15 –	.17
N-W acid, bbl.	lb.	1.25 –	1.30
Ortho-amidophenol, kegs	lb.	2.30 –	2.35
Ortho-dichlorbenzene, drums	lb.	.17 –	.20
Ortho-nitrophenol, bbl.	lb.	.90 –	.92
Ortho-nitrotoluene, drums.	lb.	.10 –	.12
Ortho-toluidine, bbl.	lb.	.14 –	.15
Para-amidophenol, base, kegs	lb.	1.20 –	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 –	1.35
Para-dichlorbenzene, bbl.	lb.	.17 –	.20
Paranitroaniline, bbl.	lb.	.72 –	.75
Para-nitrotoluene, bbl.	lb.	.60 –	.65
Para-phenylenediamine, bbl.	lb.	1.45 –	1.50
Para-toluidine, bbl	lb.	.95 –	.98
Phthalic anhydride, bbl.	lb.	.35 –	.38
Phenol, U.S.P., drums.	lb.	.50 –	.52
Picric acid, bbl.	lb.	.20 –	.22
Pyridine, dom., drums	gal.	nominal	

Pyridine, dom., drums	gal.	$2.50 - $2.75
Resorcinol, tech., kegs	lb.	1.40 - 1.50
Resorcinol, pure, kegs	lb.	2.00 - 2.25
R-salt, bbl.	lb	.55 - .60
Salicylic acid, tech., bbl.	lb.	- .42
Salicylic acid, U.S.P., bbl.	lb.	.40 - .45
Solvent naphtha, water-white, drums	gal	.37 - .40
Crude, drums	gal.	.24 -
Sulphanilic acid, crude, bbl.	lb.	.18 - .20
Thiocarbanilide, kegs	lb.	.35 - .38
Toluidine, kegs	lb.	1.20 - 1.30
Toluidine, mixed, kegs.	lb.	.30 - .35
Toluene, tank cars	gal	.30 - .35
Toluene, drums	gal.	.35 - .40
Xylidines drums	lb	.47 - .49
Xylene, pure, drums	gal	.75 - 1.00
Xylene, com., drums	gal	.37 -
Xylene, com., tanks	gal.	.32

Naval Stores

Rosin B-D, bbl	280 lb	$5.85 -
Rosin E-I, bbl	280 lb	5.95
Rosin K-N, bbl.	280 lb	6.15
Rosin W.G.-W.W., bbl	280 lb	6.50 - 7.50

Pine tar, ref., thin, bbl.	gal	- .25
Pinewood creosote, ref., bbl	gal	- .52

Animal Oils and Fats

Degras, bbl	lb	$0.03¾ - $0.04¼
Grease, yellow, bbl	lb	.06½ - .06¾
Lard oil, Extra No. 1, bbl	gal	.90 - .92
Neatsfoot oil, 20 deg bbl	gal	1.30 -
No. 1, bbl	gal	.92 - .94
Oleo Stearine		.09 -
Red oil, distilled, d.p. bbl	lb	.10½ - .10¾
Saponified, bbl	lb	.10½ - .10¾
Tallow, extra, loose	lb	.07¾
Tallow oil, acidless, bbl	gal	.94 - .96

Vegetable Oils

Castor oil, No. 3, bbl	lb	$0.14 -
Castor oil, No. 1, bbl	lb.	.14½ -
Chinawood oil, bbl.	lb.	.26 - .28
Coconut oil, Ceylon, bbl.	lb.	.09½ -
Ceylon, tanks, N.Y.	lb	.08¾
Coconut oil, Cochin, bbl.	lb	.10 - .10¼
Corn oil, crude, bbl	lb	.12¼ -
Crude, tanks, (f.o.b. mill)	lb	.09¼ - .09½
Cottonseed oil, crude (f.o.b. mill), tanks	lb	.09½ -
Summer yellow, bbl.	lb	.12¾
Winter yellow, bbl.	lb	.13½ - .13¾
Linseed oil, raw, car lots, bbl	gal.	1.13 - 1.14
Raw, tank cars (dom.)	gal	1.08 - 1.09
Boiled, cars, bbl. (dom.).	gal.	1.15 - 1.16
Olive oil, denatured, bbl	gal.	1.10 -
Sulphur, (foots) bbl	lb	.09 - .09½
Palm, Lagos, casks	lb	.07½ - .07¾
Niger, casks	lb	.07 - .07¼
Palm kernel, bbl.	lb.	.08½ - .08¾
Peanut oil, crude, tanks (mill)	lb	.13½
Peanut oil, refined, bbl.	lb.	.16¾
Perilla, bbl	lb	.16 - .16½
Rapeseed oil, refined, bbl	gal	.83 - .84
Rapeseed oil, blown, bbl.	gal.	.88 - .89
Sesame, bbl	lb	.11¾ - .12½
Soya bean (Manchurian), bbl	lb	.12½ - .13
Tank, f.o.b. Pacific coast	lb	.10½ - .10¾
Tank, (f.o.b. N.Y.)	lb	.10¾ - .10¾

Fish Oils

Cod, Newfoundland, bbl.	gal	$0.70 - $0.72
Menhaden, light pressed, bbl.	gal	.76 -
White bleached, bbl.	gal	.78 -
Blown, bbl.	gal.	.82 -
Crude, tanks (f.o.b. factory)	gal	.50 -
Whale No. 1 crude, tanks, coast	lb	-
Winter, natural, bbl	gal	.76 - .78
Winter, bleached, bbl	gal	.79 - .80

Oil Cake and Meal

Coconut cake, bags.	ton	$30.00 - $31.00
Copra, sun dried, bags, (c.i.f.)	lb	.05¼ - .05½
Sun dried Pacific coast	lb.	.05½ - .05¾
Cottonseed meal, f.o.b. mills	ton	38.00 -
Linseed cake, bags	ton	34.50 -
Linseed meal, bags	ton	36.50 -

Dye & Tanning Materials

Albumen, blood, bbl	lb	$0.45 - $0.50
Albumen, egg, tech, kegs	lb	.90 - .95
Cochineal, bags.	lb	.33 - .35
Cutch, Borneo, bales	lb	.04½ - .05
Cutch, Rangoon, bales	lb	.13 - .13½
Dextrine, corn, bags	100 lb	3.69 - 4.01
Dextrine, gum, bags	100 lb	3.99 - 4.09
Divi-divi, bags	ton	38.00 - 39.00
Fustic, sticks	ton	30.00 - 35.00
Fustic, chips, bags	lb.	.04 - .05
Logwood, sticks	ton	26.00 - 30.00
Logwood, chips, bags	lb	.02½ - .03½
Sumac, leaves, Sicily, bags	ton	70.00 - 72.00
Sumac, ground, bags	ton	$65.00 - $67.00
Sumac, domestic, bags	ton	40.00 - 42.00
Starch, corn, bags	100 lb	2.97 - 3.07
Tapioca flour, bags	lb.	.06 - .06½

Extracts

Archil, conc., bbl	lb	$0.17 - $0.18
Chestnut, 25% tannin, tanks	lb	.02 - .03
Divi-divi, 25% tannin, bbl	lb	.04 - .05
Fustic, crystals, bbl	lb	.20 - .22
Fustic, liquid, 42°, bbl	lb	.08 - .09
Gambier, liq., 25% tannin, bbl	lb.	.08 - .09
Hematine crys., bbl	lb	.14 - .18
Hemlock, 25%, tannin, bbl	lb	.04 - .05
Hypernic, solid, drums	lb	.24 - .26
Hypernic, liquid, 51°, bbl	lb	.10 - .12
Logwood, crys., bbl	lb	.18 - .20
Logwood, liq., 51°, bbl.	lb	.09 - .10
Quebracho, solid, 65% tannin, bbl	lb	.04½ - .05
Sumac, dom., 51°, bbl	lb	.06½ - .07

Dry Colors

Blacks-Carbongas, bags, f.o.b. works	lb	$0.20 - $0.24
Lampblack, bbl	lb	.12 - .40
Mineral, bulk	ton	35.00 - 45.00
Blues-Bronze, bbl	lb	.55 - .60
Prussian, bbl	lb	.55 - .60
Ultramarine, bbl	lb	.08 - .35
Browns, Sienna, Ital., bbl	lb	.06 - .14
Sienna, Domestic, bbl	lb	.03½ - .04
Umber, Turkey, bbl	lb	.04 - .04½
Greens-Chrome, C.P. Light, bbl	lb	.32 - .34
Chrome, commercial, bbl	lb	.12 - .12½
Paris, bulk	lb	.30 - .35
Reds, Carmine No. 40, tins	lb	4.50 - 4.70
Oxide red, casks	lb	.10 - .14
Para toner, kegs	lb	1.00 - 1.10
Vermilion, English, bbl	lb	1.30 - 1.32
Yellow, Chrome, C.P. bbls	lb	.20 - .21
Ocher, French, casks	lb	.02½ - .03

Waxes

Bayberry, bbl.	lb	$0.35 - $0.36
Beeswax, crude, bags	lb	.20 - .21
Beeswax, refined, light, bags	lb	.32 - .34
Beeswax, pure white, cases	lb	.40 - .41
Candelilla, bags	lb.	.21 - .22
Carnauba, No. 1, bags	lb	.42 - .43
No. 2, North Country, bags	lb	.23 - .23½
No. 3, North Country, bags	lb.	.18½ - .19
Japan, cases	lb	.16½ - .16¾
Montan, crude, bags	lb.	.04½ - .04¾
Paraffine, crude, match, 105-110 m.p.	lb.	.04 - .04¼
Crude, scale 124-126 m.p., bags	lb	.02¾ - .03
Ref., 118-120 m.p., bags	lb.	.03 - .03¼
Ref., 125 m.p., bags	lb	.03½ - .03¾
Ref., 128-130 m.p., bags	lb.	.03¾ - .04
Ref., 133-135 m.p., bags	lb	.04½ - .04¾
Ref., 135-137 m.p., bags	lb.	.05 - .05¼
Stearic acid, sgle pressed, bags	lb.	.13 - .13½
Double pressed, bags	lb	.13½ - .13¾
Triple pressed, bags	lb	.15 - .15½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb	$3.25 - $3.30
F.a.s. double bags	100 lb	3.85 - 3.90
Blood, dried, bulk	unit	4.00 -
Bone, raw, 3 and 50, ground	ton	27.00 - 30.00
Fish scrap, dom., dried, wks.	unit	3.75
Nitrate of soda, bags	100 lb.	2.52½ - 2.57½
Tankage, high grade, f.o.b. Chicago	unit	3.35 - 3.45
Phosphate rock, f.o.b. mines,		
Florida pebble, 68-72%	ton	$4.00 - $4.50
Tennessee, 78-80%	ton	8.00 - 8.25
Potassium muriate, 80%, bags	ton	34.55 -
Potassium sulphate, bags basis 90%	ton	43.67 -
Double manure salt	ton	25.72 —
Kainit	ton	7.22 —

Crude Rubber

Para—Upriver fine	lb	$0.27¾
Upriver coarse	lb	.23 - .23½
Upriver caucho ball	lb	.24½ - .25½
Plantation—First latex crepe	lb	.27¼ -
Ribbed smoked sheets	lb	.27¼ -
Brown crepe, thin, clean	lb.	.26½ -
Amber crepe No. 1.	lb.	.27 - .27¼

Gums

Copal, Congo, amber, bags	lb.	$0.12 - $0.13
East Indian, bold, bags	lb.	.23 - .23½
Manila, pale, bags	lb.	.20 - .20½
Pontinak, No. 1 bags	lb.	.20 - .20½
Damar, Batavia, cases	lb	.28 - .29
Singapore, No. 1, cases	lb.	.34 - .35
Singapore, No. 2, cases	lb.	.23 - .24
Kauri, No. 1, cases	lb	.65 - .67
Ordinary chips, cases	lb	.20 - .22
Manjak, Barbados, bags	lb	.09 - .09½

Shellac

Shellac, orange fine, bags	lb.	$0.64 -
Orange superfine, bags	lb.	.66 -
A. C. garnet, bags	lb.	nominal
Bleached, bonedry	lb	.73 -
Bleached, fresh	lb.	.61 - .62
T. N., bags	lb.	.60 - .61

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$500.00 -
Asbestos, shingle, f.o.b., Quebec	sh. ton	$65.00 - $85.00
Asbestos, cement, f.o.b., Quebec	sh. ton	20.00 - 25.00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 - 20.00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13.00 - 15.00
Barytes, floated, f.o.b. St. Louis, bbl	net ton	28.00 -
Barytes, crude f.o.b. mines, bulk	net ton	10.00 - 11.00
Casein, bbl., tech.	lb	.19½ - .23½
China clay (kaolin) crude, f.o.b. Ga	net ton	7.00 - 9.00
Washed, f.o.b. Ga.	net ton	8.00 - 9.00
Powd., f.o.b. Ga	net ton	14.00 - 20.00
Crude f.o.b. Va	net ton	8.00 - 12.00
Ground, f.o.b. Va	net ton	14.00 - 20.00
Imp., lump, bulk	net ton	15.00 - 20.00
Imp., powd	net ton	45.00 - 50.00
Feldspar, No. 1 pottery	long ton	6.00 - 7.00
No. 2 pottery	long ton	4.00 - 5.50
No. 1 soap	long ton	7.00 - 7.50
No. 1 Canadian, f.o.b. mill	long ton	20.00 - 22.00
Graphite, Ceylon, lump, first quality, bbl	lb	.06½ -
Ceylon, chip, bbl.	lb	.05¾ -
High grade amorphous crude	ton	15.00 - 35.00
Gum arabic, amber, sorts, bags	lb	.14½ - .15
Gum tragacanth, sorts, bags	lb	.48 - .56
No. 1, bags	lb	1.50 - 1.60
Kieselguhr, f.o.b. Cal	ton	40.00 - 42.00
F.o.b. N.Y.	ton	50.00 - 55.00
Magnesite, crude, f.o.b. Cal.	ton	14.00 - 15.00
Pumice stone, imp., casks	lb	.03 - .05½
Dom., lump, bbl	lb	.05 - .05½
Dom., ground, bbl	lb	.06 - .07
Silica, glass sand, f.o.b. Ind.	ton	2.00 - 2.50
Silica, sand blast, f.o.b. Ind.	ton	2.50 - 5.00
Silica, amorphous, 250-mesh, f.o.b. Ill	ton	17.00 - 17.50
Silica, bldg. sand, f.o.b. Pa.	ton	2.00 - 2.75
Soapstone, coarse, f.o.b. Vt., bags	ton	7.00 - 8.00
Talc, 200 mesh, f.o.b. Vt., bags	ton	6.50 - 9.00
Talc, 200 mesh, f.o.b. Ga., bags	ton	7.00 - 9.00
Talc, 200 mesh, f.o.b. Los Angeles, bags	ton	16.00 - 20.00

Mineral Oils

Crude, at Wells

Pennsylvania	bbl.	$3.25 - 3.50

Seamless high brass tubing	23 50

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

Copper, heavy and crucible	11.60@11.80
Copper, heavy and wire	11 50@11.60
Copper, light and bottoms	10 00@10.10
Lead, heavy	5.75@ 6.00
Lead, tea	3.50@ 3 75
Brass, heavy	6.50@ 6 75
Brass, light	5.75@ 6 00
No. 1 yellow brass turnings	6.75@ .700
Zinc	3.75@ 4.25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$3.29	$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

California

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg, San Francisco, has work in progress on the first unit of its new refining plant at Wilmington, Los Angeles harbor, 210x252 ft, for which a general contract recently was awarded to the Davidson Construction Co, 1445 East 16th St., Los Angeles A power plant will be erected on adjoining site The structures, exclusive of equipment, will cost $418,000.

Georgia

EAST POINT—The Marion-Harper Oil Co. has tentative plans under consideration for the rebuilding of the portion of its cotton oil mill, destroyed by fire, May 14, with loss estimated at $50,000, including equipment.

Florida

ST. PETERSBURG—W. A. Kerr, 338 8th Ave., North, and associates are organizing a new company to construct and operate a local plant for the manufacture of inks and kindred products. Plans will be prepared at an early date.

Illinois

CHICAGO—Fritzsche Brothers, Inc., 82 Beekman St., New York, N. Y., manufacturer of essential oils, has purchased property at 118 East Ohio St., Chicago, as a site for a new plant. Plans will be prepared at an early date

CHICAGO—Gutmann & Co., 1511 Webster St, operating a tanning plant, will commence the immediate erection of a new 2-story tannery at Webster and Dominick Sts, 78x190 ft, estimated to cost $125,000, with equipment I. B. Stern is company architect.

DECATUR—The Home Oil Co, Arthur, Ill., is considering plans for a new branch works in the Cerro Gordo district, Decatur F. C. Phillips is general manager

Indiana

INDIANAPOLIS—The Bryan Pyroxylin Co has arranged for the operation of a new plant at Shadeland Ave. and the Pendleton Pike for the manufacture of composition products

INDIANAPOLIS—The Fairmount Glass Works, Inc., Keystone Ave, is considering tentative plans for a new plant on property recently acquired at Alabama and St. Clair Sts, 130x195 ft., to be used for the manufacture of hollow-ware products. John Rau is president

Kansas

WICHITA—The Roxana Petroleum Corp, Roxana, Ill. and Tulsa, Okla, is perfecting plans for the erection of its proposed new oil refinery on property acquired near Wichita, totaling 200 acres of land. The initial plant units will have a capacity of 5,000 bbl. per day and will cost close to $2,000,000, with machinery. The ultimate refinery will have a total output of 10,000 bbl., and is estimated to cost $4,000,000.

Kentucky

OWENSBORO—The Owensboro Clay Products Co., recently organized with a capital of $1,000,000, has preliminary plans for the establishment of a new plant estimated to cost in excess of $150,000, with machinery. John A. Bolger, Owensboro, heads the company.

Louisiana

BASTROP—The United States Carbon Co. is arranging for the erection of a new plant for the production of carbon black on local site, recently purchased. It will consist of two units, each comprising 36 buildings, with total daily production of 10,000 lb. of material The plant will cost in excess of $200,000, including equipment. Leonard Biddison heads the company.

MONROE—The Standard Carbon Co. has plans under consideration for extensions in its local plant, including the installation of additional machinery

Maine

PHIPPSBURG The Basin Quarries, Inc., Portland, Me, organized with a capital of $100,000, has plans under way for the erection of a new feldspar, quartz and mica plant, with pulverizing, screening and grinding departments, estimated to cost $50,000 with machinery. The mill will have an initial capacity of 30 tons per day. Joseph F. Perry is president, and Frank L. Marston, vice-president.

RUMFORD—The Oxford Paper Co. is arranging plans for a new addition to its bleach plant, 50x216 ft., to provide for an increased output of 1,900 tons of electrolytic bleach and 75 tons of caustic material. Extensions will also be built to the machine and beater buildings

Maryland

HAGERSTOWN—The Hagerstown Lime & Chemical Co. is completing the construction of a new plant on the State Road, near the city limits, on 112-acre tract of land recently purchased, and will commence operations at an early date for the manufacture of fertilizer products.

WOODLAWN (Baltimore)—The Powhatan Mining Corp., recently formed with a capital of $100,000, has tentative plans under consideration for the development of an extensive tract of asbestos property and the construction of a mill. Fred A. Mett is president and general manager; and K. H. Kiefer, vice-president.

Michigan

WATERVLIET—The Watervliet Paper Co. will make extensions and improvements in its plant, including the installation of electrical and other equipment.

MARINE CITY—Plans are being arranged for a reorganization of the Independent Sugar Co. and the early resumption of operations at the mill. The property will be offered for sale by the receiver on June 5, and will be acquired by the new interests. Extensions and improvements are planned.

New Jersey

TRENTON—The J. L. Mott Co., Hancock Ave., manufacturer of enameled iron products, has commenced the rebuilding of the portion of its enameling plant, recently destroyed by fire with loss estimated at $25,000, including equipment.

New York

CORNWALL—The Cornwall Chemical Corp., 111 Water St., New York, is said to be perfecting plans for the rebuilding of the portion of its plant at Cornwall, recently destroyed by fire with loss estimated at $100,000, including equipment.

GLENS FALLS—The Raymond Pectoral Plaster Co., Thompson Ave., has had plans prepared for the construction of a new 2-story and basement plaster mill, estimated to cost $25,000. Wetmore & Crandall, Inc., Glens Falls, are architects.

North Carolina

WILMINGTON—The Wilmington Pottery Co. has plans nearing completion for its proposed new plant at Surry and Wright Sts, for the manufacture of cement products. The company will remodel an existing building and install machinery. R. H. Young, Charlotte, N. C., is head.

Ohio

LIMA—The Lily White Oil Co., recently acquired by the Roxana Petroleum Co., Roxana, Ill., to be operated as a subsidiary organization, has tentative plans under con-

sideration for the erection of a new plant for the manufacture of lubricating oils, estimated to cost about $300,000, with machinery.

Pennsylvania

PITTSBURGH—The Waverly Oil Co., 54th St. and the Allegheny Valley Railroad, is having plans drawn for the erection of an addition to its plant to be equipped as a gasoline refinery. It is estimated to cost in excess of $100,000, including machinery. The Hunting-Davis Co., Century Building is engineer.

NILES—The Ohio Galvanizing Co., Ann St., is considering plans for the erection of a new 1-story addition to its plant, 100x125 ft., to cost about $15,000. F. F. Bentley is head.

PITTSBURGH—The Aiken Oil Co., Crafton Pa., has purchased property comprising about 2 acres of land near Woodville and Banksville Aves. as a site for a new plant for the manufacture of lubricating oils. Plans have been drawn and work will be commenced at an early date. Complete processing and other machinery will be installed. F. L. Aiken is president.

NEW CASTLE—The Shenango China Co. will make extensions and improvements at its local pottery, including the installation of additional equipment. A number of new kilns will be built.

BETHLEHEM—The Bethlehem Spark Plug Co., Inc., manufacturer of porcelain spark plugs, is arranging to increase production at its plant. The company has contracted to furnish all spark plugs required by the United States Post Office Department for the coming fiscal year.

Tennessee

KNOXVILLE—The American Glass Co has perfected arrangements for the establishment of a new plant at property recently acquired at 211 West Clinch St, and will install equipment.

Texas

DALLAS—The Shook Rubber Co., 2500-2 South Ervay St., will commence the immediate construction of a new 3-story works to cost about $35,000, exclusive of equipment.

HOUSTON—The Texas Portland Cement Co., Praetorian Bldg., Dallas, is completing plans and will soon commence the erection of an addition to its plant at Manchester, near Houston, estimated to cost about $30,000, exclusive of equipment. Grinding and other machinery will be installed to cost approximately $60,000. William Moeller is general superintendent.

EASTLAND—The Arab Gasoline Co., 23rd and Westmoreland Sts., Philadelphia, Pa., has plans under way for extensions in its gasoline-refining plant at Eastland, estimated to cost about $90,000, including equipment. The company has recently increased its capital to $700,000 for general expansion.

HOUSTON—The Myer Spalti Mfg. Co has plans under consideration for the erection of a new plant on local site, for the manufacture of cement and concrete products, estimated to cost $100,000, including equipment.

DALLAS—The Texas Co., 17 Battery Place, New York, is considering plans for extensions and improvements in its oil-refining plants in Texas and other localities, to cost close to $1 500,000 with equipment. The company has acquired a controlling interest in the Carib Syndicate, Ltd. for expansion in its refinery facilities.

HEARN—The Austin Cotton & Planters' Mills, Inc., is having plans prepared for a new cotton oil mill, to be 80x300 ft., estimated to cost close to $60,000, with equipment. Edwin C. Kreile, 803 Scarborough Bldg., Austin, Tex., is architect.

HOUSTON—The Magnolia Paper Co is completing plans for a new 3-story works at Pickney and Glaser Sts., estimated to cost close to $50,000. Work will soon be commenced.

Washington

VANCOUVER—The Columbia River Paper Mills Corp. will commence the installation of a new acid system at its sulphite plant. Other equipment will be installed later.

West Virginia

CHARLESTON—The Evans Lead Co. has commenced the erection of the first unit of its proposed local plant, comprising a 1-story building, 75x120 ft., and will install machinery at an early date. The company is also planning for the construction of a new laboratory building.

Industrial Notes

THE DORR CO. has moved its New York office from 101 Park Ave to 247 Park Ave.

THE OILGEAR CO. of Milwaukee, Wis., has recently appointed the Buffalo Machinery Sales Corp., 881 Ellicott Square, Buffalo, as sales representative for Oilgear products in the western New York territory. Announcement is also made that W. D. Creider, formerly in charge of the Milwaukee office of the Federal Machinery Sales Co. of Chicago, has been appointed sales manager of the Oilgear Co. at Milwaukee and that A. L. Ellis, for the past year acting sales manager at Milwaukee, has been appointed Eastern representative of the company, with headquarters in New York City.

THE PURE CARBON CO., Wellsville, N. Y., has recently established a Minneapolis representative in the firm of Charles A. Etem Co., 914-A Marquette Ave., Minneapolis, Minn.

The offices of the MINING AND METALLURGICAL SOCIETY OF AMERICA are now located at 2 Rector Street, New York City.

GIFFORD WOOD CO., of Hudson, N. Y., has changed the location of its Buffalo office to the Peoples Bank Bldg., Corner 4th Ave. and Wood St., Pittsburgh, Pa.

THE BARTLETT HAYWOOD CO. announces the removal of its New York office to 1607 Pershing Square Bldg., 42nd St., at Park Ave.

JOSEPH W. HAYS has organized a corps of consulting combustion engineers to be known as Joseph W. Hays and Associates. The headquarters of the organization will be Michigan City, Ind. It is prepared to render consulting service in steam plants in all parts of the country since no change will be made in the place of residence of any of the associates, and each member will look after the engineering work in his immediate territory.

THE GEORGE J. HAGAN CO. has moved its offices from the Peoples Bank Bldg. to the Chamber of Commerce Building, Pittsburgh, Pa.

THE PHILADELPHIA DRYING MACHINERY CO., Philadelphia, Pa., announces that Whitehead, Emmans, Ltd., of Montreal and Hamilton, Canada, will be its Canadian agent.

THE LINK-BELT CO.'s Pittsburgh branch office has been moved to 335 Fifth Ave.

THE CARBORUNDUM CO., Niagara Falls, N. Y., announces the appointment of Harry Collinson as district sales manager in charge of its Milwaukee office and warehouse. Mr. Collinson assumed the position May 1, succeeding J. H. Jackson, resigned. Mr. Collinson was previously district sales manager of the Carborundum Co. in the Province of Ontario. In this position he was succeeded by C. E. Bowman, lately connected with the sales department of Norman Macdonald, who has the agency for Carborundum products at Toronto, Ont.

New Companies

OKLAHOMA FIBER CO., Durant, Okla.; fiber products, $100,000. Incorporators: George F. Beck, Durant; and Guy C. Wallace, Caddo, Okla.

DIAMOND COLOR & CHEMICAL CORP., Jersey City, N. J.; chemicals, chemical byproducts, etc.; $20,000. Incorporators: Arthur R. Oakley and Robert A. Van Voorhis. Representative: Registrar & Transfer Co., 15 Exchange Place, Jersey City.

BAY CHEMICAL CO., Brooklyn, N. Y.; chemicals and chemical byproducts; $100,000. Incorporators: W. Kopp and C. Seifert. Representative: C. O. Echler, 481 Knickerbocker Ave., Brooklyn.

MANOLITS CARBON PAINT CO., Cincinnati, O.; paints, enamels, etc.; $500 000. Incorporators: E. Cunningham and N. C. Kelley, both of Cincinnati.

DENTAPERL CHEMICAL CO., INC., 1913-15 West Harrison St., Chicago, Ill., chemicals and chemical byproducts, $10,000. Incorporators: Howard Golden and John E. Rowe.

LYON LEATHER CO., Manchester, Conn., leather products; capital $50,000. Incorporators: C. E. House, W. A. Strickland and C. R. Burr, 138 Main St., Manchester.

MALTOSE CORP. OF NEW JERSEY, INC., Jersey City, N. J., glucose and kindred products, 20,000 shares of stock, no par value. Incorporators: John Milton, J. L. Ridley and John J. Tracy, 1 Exchange Place, Jersey City. The last noted is representative.

DIXIE INK CO., Mobile, Ala.; ink, adhesive products, etc.; $10,000. Incorporators: E. C. Bristol, John Whilburn and D. D. Gimon, all of Mobile.

DERMATAN CHEMICAL CO., New York, N. Y.; chemicals and chemical byproducts; $15,000. Incorporators: D. Ambrose, G. W. Moser and A. A. Cone. Representative: A. G. Mintz, 305 Broadway, New York.

CHARLES V. SPARHAWK CORP., Wilmington, Del.; chemicals and chemical byproducts; $200,000. Representative: Colonial Charter Co., Ford Bldg., Wilmington.

PERFECTION PAINT & PRODUCTS CORP., Room 815, 8 South Dearborn St., Chicago, Ill.; paints, varnishes and kindred products; $25,000. Incorporators: Henry Rutz, A. R. Sherick and Mortimer A. Sherick.

ATHENS FIRE BRICK CO., Athens, Tex.; firebrick and refractories; $25,000. Incorporators: T. A. Bartlett, A. S. Coke and C. D. Gregg, all of Athens.

VINE CHEMICAL CO., Jamestown, N. Y.; chemicals and chemical byproducts; $50,000. Incorporators: R. Osgood, L. Vine, and W. C. Davidson. Representative: A. C. Nelson, attorney, Jamestown.

HELVETIA OIL CO., San Antonio, Tex., petroleum products, $200,000. Incorporators: W. M. Aikman, K. R. Potts and W. C. Steubing, all of San Antonio.

FROST CORP., Wilmington, Del.; glass products; $100,000. Representative: Corporation Trust Co. of America, du Pont Bldg., Wilmington.

M & L RUBBER CO., 3025 Indiana Ave., Chicago, Ill.; rubber products; $20,000. Incorporators: W. M. Legnard, A. B. Legnard and A. E. McGregor.

HERCULITE PRODUCTS CORP., Jersey City, N. J., celluloid and composition products, $600 000. Representative: United States Corporation Co., 15 Exchange Place, Jersey City.

LINCOLN OIL MILLS CO., Lincolnton, N. C., refined oil products; $50,000. Incorporators: K. B. Nixon, R. F. Beal and J. E. Lipscomb, all of Lincolnton.

J. SCHANZENBACH & CO., INC., New York, N. Y.; chemicals and chemical byproducts, $10,000. Incorporators: J. Schanzenbach, A. B. Rose and J. A. Mitchell. Representative: Brown, Cropsey & Nines, 29 Broadway, New York.

BLUE BONNETT LIME CO., Fort Worth, Tex.; lime products; nominal capital, $6,000. Incorporators: A. D. and D. D. Thompson and G. W. Harding, all of Fort Worth.

HAWTHORNE GLASS CO., 3650 52nd Ave., Cicero, Ill., glass products, 500 shares of stock, no par value. Incorporators: F. H. King, Thomas J. Harper and E. A. Moynihan.

RESISTO PIPE & VALVE CO., 262 Bridge St., Cambridge, Mass.; acid-resisting lined iron pipe, valves, pumps, tanks, etc.; $100 000. E. A. Taft, president; G. A. MacDowall, treasurer.

THORBETTE OIL CORP., Wilmington, Del.; refined oil products; $1,000,000. Representative: Corporation Trust Co. of America, du Pont Bldg., Wilmington.

POLY CHEMICAL LABORATORIES, INC., Jersey City, N. J.; chemicals and chemical byproducts, $25,000. Incorporators: Frank Haber, Louis Rothstein and George P. Williamson. Representative: Ezra L. Nolan, 25 Old Bergen Rd., Jersey City.

Opportunities in the Foreign Trade

Parties interested in any of the following opportunities may obtain all available information from the Bureau of Foreign and Domestic Commerce at Washington or from any district office of the bureau. The number placed after the opportunity must be given for the purpose of identification.

COTTONSEED OIL, sesame oil, soya oil and peanut oil. Belgrade, Jugoslavia. Purchase or agency.—6449.

TIN PLATE for making sardine cans. Vigo, Spain. Purchase.—6459.

PAPER, PRINTING INKS. Rio de Janeiro, Brazil. Agency.—6479.

WALL PAPERS, principally job borders and friezes, both cut-outs and straight. London, England. Purchase and agency.—6471.

ALLOYS of aluminum and silicate, providing 10 per cent silicon. Lyon, France. Purchase.—6486.

PAINTS AND BUILDING MATERIAL. Berne, Switzerland. Agency.—6489.

OXIDE OF TIN (extra light for enameling on iron), in quantity of 2, 3 or 5 ton lots. Newcastle, England. Purchase.—6490.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 New York, June 4, 1923 *Number* 22

Future Progress in Steel Making

MOST of the "big men" who attend the meetings of the American Iron and Steel Institute go to hear Judge GARY'S estimate of the trade conditions, to meet their business friends and competitors, and to discuss with them the state of the union. Then there are a large number of plant managers and engineers whose main interest is to renew acquaintances and find out what the other fellow is thinking about and doing. Finally, there may be found a larger number of men who do business with the other groups (or would like to) who are there because it is a good place to be.

In such a gathering one anticipates that science and technology would occupy inconspicuous seats. However, they are very useful to fill in between the president's opening address and dressing time for the banquet. They are quite distinguished and above any suspicion which might survive from "Gary dinners," and it is well that they are useful in these circumstances, as in many others. If it were not for the technical program—prepared often by mandatory invitation—a large part of our huge metallurgical industry would be inarticulate.

Knowing the origin of some papers on the program and guessing at the careful scrutiny they receive before release, it is perhaps permissible to place more weight on a statement that "only through unremitting and untiring research can chemistry continue to serve the steel industry as it has in the past" when coming from a metallurgist with the Steel Corporation than if it came from a chemist with the Bureau of Standards. Can it be that the remark reflects the tardy realization that the steel companies in America are very remiss in studying the essence of their processes? Few are so backward that they have no investigations of any sort under way, but in nearly every instance they are working on minor plant troubles or disputes with customers.

But there seems to be an undercurrent of opinion that we are on the very brink of revolutionary changes. The minute it is admitted that the conventional steel plant has nearly reached its theoretical possibilities, it immediately follows that the next improvements will come through radically different methods. If, for instance, the mechanical gas producer cannot be appreciably improved, when may we expect the "slagging gas producer" gasifying coal at ten times the rate? If the iron blast furnace has reached its limit, is not that very fact ushering in the new metallurgy which will exist when oxygen is produced for five dollars a ton? (One hears that two thoroughly trustworthy organizations are guaranteeing less than that figure!) Or for that matter, cannot the principles of ore concentration, so well known in the West, be used to produce a very pure iron oxide, and this be reduced directly to high-grade steel without the expensive refining operation?

Truly, it would be well for the large producing interests to gather to themselves men of vision and widest scientific training, so that they will be forewarned and prepared against discoveries which can turn a million dollars worth of steel plant into a few thousand dollars worth of junk.

Bio-Chemical Engineering

SIGNIFICANT REMARKS made recently by Dr. C. P. STEINMETZ indicate the interrelation of the sciences and the need for a catholicity of viewpoint on many of the research problems of the day. For example, economical sugar production demands more than a consideration of the final phases of processing; much of the success of the beet-sugar industry in recent years has been due to the intensive cultivation of the plant, by which the yield of sugar per unit of weight has been increased largely. The distinguished engineer of the General Electric Co. spoke of biological engineers, citing LUTHER BURBANK as the dean of a new professional group. There is nothing incongruous in the new classification. If one accepts the verdict that an engineer is essentially creative, it must be admitted that Mr. BURBANK is more entitled to the use of the appellation than is the individual who manipulates levers, or who directs the process of exterminating insects, or who moves furniture, or who turns a deaf ear to our pleas for heat in winter time. There is a close connection between biology, chemistry and the supply of fuel for the human frame.

Comparatively recently we have begun to realize the connection between biology and the supply of ordinary fuel, which suggests that future power requirements may be met in whole or in part by the intensive cultivation and the economic utilization of plant life. The simplest manner of taking advantage of this possibility is to permit the sun to function at maximum efficiency, for light is an essential to the process. We know that deposited crystals need be removed from an evaporator as they form, else efficiency drops rapidly; similarly, no estimate of the possible value of natural biological products is possible without taking into consideration the advantages of scientific harvesting. Thus it has been proved that seaweed may be cut from shallow-water deposits at frequent intervals, whereupon Nature replenishes the store of raw material for the possible supply of potash, iodine and other byproducts. Recent biochemical research has shown that at least one type of seaweed, in the presence of an ample supply of carbon dioxide, can fix atmospheric nitrogen and form carbohydrates and protein; that bacteria unconnected with

leguminous plants can nitrify the soil; that the wheat plant can assimilate free nitrogen from the atmosphere. Scientific progress in this direction indicates that we are probably on the threshold of discoveries of importance, discoveries that may profoundly affect the problem of nitrate production for fertilizer purposes; and it behooves the chemical engineer, for economic as well as for technical reasons, to keep in close touch with the advances being made in a closely related science.

A Self-Starter In Automotive Research

A FEW YEARS AGO there was scarcely an industry so backward in scientific interest and acumen as the automobile industry. But there came a day when the manufacturers began to sense that a pink-powder puff and a cigar lighter in the body of a car would no longer serve as selling arguments. There was less talk about the "perfect car" that used 4 or 5 per cent of the energy of the gasoline and wasted the rest. This change in attitude is traceable almost directly to the achievements of a single laboratory out in Dayton, Ohio.

The other night at a dinner it was our privilege to sit beside C. F. KETTERING, head of the General Motors Research Corporation. We found him neither solemn, nor glum, nor cryptic. He is, according to the slang of the day, a live wire. To hear him talk for an hour is a liberal education. The incidence of a successful mind on research is always interesting and for the benefit of our readers we want to quote from memory a few of his observations as well as a story or two told us by one of his associates. A problem in hand included 18 months' work with negative results. The report was 300 pages long. When it was brought to Mr. KETTERING he was not interested; said he "wouldn't give a damn for it"; it was not complete. "There are 300 blank pages on the backs of this record," said he, "and there is room to put down the reasons why you did not succeed. Please see that they're there before you bring it back to me." This very study developed the key to the solution of an important problem in the automotive industry. It brought out the fact that a material was needed that was not available. The next and rather simple step in the procedure was to find that material.

He has no patience with the substitution of mathematics for physical chemistry. Mathematics, he insists, is a tool of no value whatever until you have an idea. "If I want to build a garage," said he, "I don't need mathematics until I have made up my mind what I want, where my garage is to be built and how the windows and doors are to be placed. I must see it in my mind's eye first. Then it is time for me to begin to measure, not before." It goes without saying that mathematics as a tool is in constant and active use in the Dayton laboratory.

It is easy to understand why those who work with him love to do so. It is lively business—exceedingly lively business. He expects everybody to think for himself, and not to dawdle about it either. To him science is all one great subject so interrelated in its various parts that the research chemist who cannot grasp a problem in mechanics is not an adequate chemist, nor is the engineer who cannot sense a problem in chemistry a complete engineer.

The story is told of an address he made to a class of graduating engineers in one of the leading universities. He offered handsome fellowships to any members of the class who could answer a simple question within 60 seconds. "Why," he asked, "does a sharp knife cut better than a dull one?" There was no answer forthcoming. He expects a reason in mechanical philosophy for everything that happens.

He encourages opinions, wants lots of them, but will brook no confusion between an opinion and a fact. The distinction between the two is very clear in his mind, and he does not seem ever to forget it.

TOM MIDGELEY, of whose work in overcoming the knock in internal-combustion engines we have published considerable already, said: "We had worked 2 years on this problem without results. Then Mr. KETTERING furnished the hell that gave us the necessary religion to enable us to worry out our salvation."

One doesn't need champagne or any other stimulant to liven up the talk if C. F. KETTERING sits across the table; especially if one is interested in research. The difficulty is to keep the sparks alight and to remember them all when the evening is over.

Reserves of Natural Nitrate

BY PUBLICATION last fall of an exhaustive report on the economic value of the nitrate in Californian deserts, the U. S. Geological Survey set at rest many rumors as to the possibility of starting domestic production somewhat on the lines of the Chilean nitrate industry. The conclusions reached indicated that nitrate occurs in the United States in insignificant amount, which it would not pay to recover. The possibility of discovering deposits other than those that are already known is so remote as to be of negligible significance. It is, therefore, a matter of considerable importance at the present time that industry form a correct impression of the reserves of this most important raw material.

The policy of underrating the resources of a competitor is one that is likely to prove a boomerang. At the annual meeting of the British Association for the Advancement of Science at Bristol, England, in 1898, Sir WILLIAM CROOKES, noted physicist, shared honors with the fake explorer, LOUIS DE ROUGEMONT, in startling the world. The latter held his audience spellbound while he recounted an amazing series of adventures in a country which, it was discovered later, he had never even visited. Sir WILLIAM predicted an almost immediate nitrate famine, consequent on the early exhaustion of the deposits of caliche in Chile. His national and international reputation served to add weight to his contention, with the result that the prophecy has reverberated for 25 years, being used as a text by writers of all types and aspirations and for purposes too numerous to mention. During the war it served to awaken interest in preparedness, which was justifiable; but it is pertinent to note that after all the great conflict was won with Chilean nitrate, and that the South American industry in the meantime has pursued the even tenor of its way. Apart from the effect of economic fluctuations caused by the war aftermath, in spite of steadily increasing output, the Chilean deposit has shown no evidence of strain, much less of exhaustion, since the utterance of Sir WILLIAM'S prophecy.

During the past 2 years an attempt has been made in the technical press of the United States to present the facts, as determined by first-hand experience, and to explain the real situation in Chile. The conclusions that

have withstood the acid test of criticism suggest that the air of secrecy which has shrouded the industry has been due in large measure to the deplorable technological standards prevailing on the pampa, consequent on the retention of inefficient methods of beneficiation and inadequate scientific control. The lack of definite statistics as to the technical operation of the plants has synchronized with a professed ignorance of the exact amount of caliche available for future mining, which, however, is easily explicable: The cost of the investigation necessary would be prodigious, and the Chilean Government would be stupid to incur the expense. Further, the introduction of efficient, large-scale methods of beneficiation and modern ore-handling equipment will permit the addition to the known reserves of an immense amount of low-grade caliche the economic value of which is now considered negligible.

It is generally conceded by engineers who have visited the country that the Chilean deposit is too gigantic and too scattered to permit statistical estimate of quantity or to justify pessimistic opinion as to probable life. Recently a change of tone is noticeable in published statements. For instance, Sir E. J. RUSSEL, the director of the Rothamstead Experimental Station, writes in *Discovery* that the caliche has been estimated to last from 200 to 300 years, adding that "the period is not long in the history of the world." True; but even after a heavy discount, the estimate is one that will occasion no alarm to the Chilean authorities. If it is necessary to pare the export tax, which brings so much to the national coffers, to meet competition with synthetic nitrate, the government will doubtless transfer the tax to copper, which, thanks to the utilization of efficient large-scale methods, is now being produced at an exceedingly low figure in the Chuquicamata plant. For the immediate future, therefore, Chile has no qualms.

In the United States, however, the problem is different. Adequate preparation against national emergency would be a fundamentally wise precaution; and this can be insured only by the maintenance, in successful operating condition, of sufficient synthetic nitrate plants to insure independence from foreign supplies in the event of international complications. It is only remotely possible that such plants could compete with the natural product under ordinary conditions, after considering the possibility of the removal of the export tax and the cheapening of production by the introduction of modern methods; but this fact should not deter research and the formulation of a definite policy in anticipation of every possible national contingency.

At some time in the future all the nations of the world will be self-supporting in regard to nitrate: the principal source of the raw material—air—will be available to all on equal terms. Those countries favored with ample water power and possessed of skilled technologists will fare best. At such time the United States will have no cause for apprehension. In the meantime it is pertinent to recall Germany's action before the war in purchasing, cheaply, immense amounts of nitrate from Chile; statistics show an importation into Germany of over three quarters of a million tons per annum prior to August, 1914. The productiveness of her land was so increased that the yield of wheat per acre was raised to 35 bushels, as compared with 15 in the United States, and the yield of potatoes mounted in about the same proportion. It may be suggested that a concentrated output permits cheaper harvesting, and that the amount of Chilean nitrate being imported into the United States at the present time might be increased with advantage to all concerned. It has also been proposed that large stocks should be purchased and stored in the arid regions of this country. In any event, the American chemical engineer should be encouraged to lend his aid in the efficient recovery of nitrate in Chile, to remedy the deplorable technical conditions that exist; so that reduced cost of production would stimulate increased utilization, more efficient farming and a market for American equipment.

Reducing the Fire Risks In Chemical Plants

TO THE average manufacturer, particularly in our chemical engineering industries, the underwriter of fire insurance is a bugbear whose periodic visits to the plant are filled with many anxious and heart-sinking moments. This attitude of fear and trepidation may be the result of sad experiences in the past or it may be the manufacturer's idea of expediency, but in any event it only hints at the real difficulty in the situation. What is most needed is a community of understanding between the industry and those who are endeavoring to indemnify it against the ravages of fire.

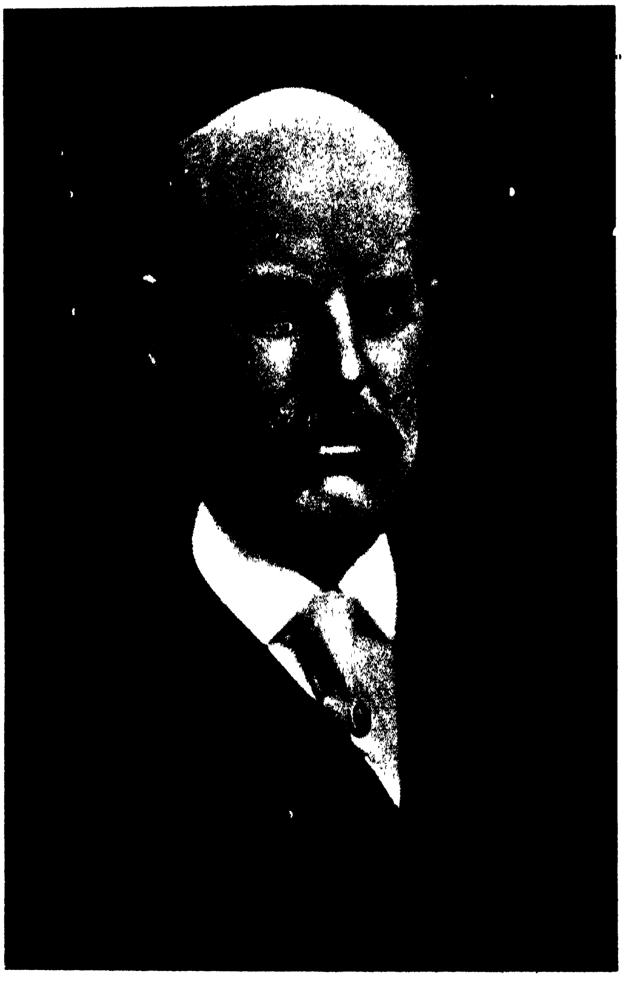
Our manufacturing procedures are as a closed book to the average underwriter. Discouraged at the complicated chemical reactions involved and the manufacturer's reticence in explaining them, the insurance man often finds himself thrown back on his own resources and judgment. Naturally he is likely to err. For example, in at least one fire insurance company of which we have knowledge, any sublimation process is regarded as an obstacle to the acceptance of a chemical plant. The reason for this is that during the war, when haphazard methods were more generally in vogue, a certain manufacturer heated his sublimers over an open fire and in the disaster that followed his plant was completely destroyed. The folly of condemning all sublimations merely because of such an unfortunate experience is, of course, obvious, but it calls attention to a neglected duty on the part of our technical men. They hold the solution to problems of this kind in their own hands. They understand the conditions to be met and were they to co-operate with the underwriters in deciphering these fire hazards, they could pave the way for remedial measures of benefit to both the insurer and the insured.

An interesting example of what can be accomplished in this way was shown in the case of a dye plant the manufacturing procedures of which involved only a single hazardous operation. The underwriter correctly judged that the entire plant was thus endangered and he recommended and collected an unusually high rate for the insurance. Later on the case came to the attention of the chemical engineer in the plant, who immediately recommended that the dangerous process be removed from the other operations. As a result of this segregation the plant became a better fire risk, the insurance was materially reduced and this in turn had its effect as a considerable saving in manufacturing costs.

The fact that in these individual cases frank discussion between the technical man and the insurance company has proved so effective suggests the possible benefit that might come from concerted efforts on the part of our industries. Appropriate committees from our trade associations or technical societies should find here a proper field for constructive study and co-operation.

Edward G. Acheson

Whose achievements in the domain of industrial electrochemistry have written a new chapter in the Romance of Technology.



THE early careers of men of achievement are especially interesting to the Professors of Can-do in the great University of Hard Knocks. For the more particular benefit of these we shall record a few notes on Dr. Edward G. Acheson while he Was Himself in the Making.

His father was manager and part owner of a blast furnace at Washington, Pa., where he was born. Will Stewart, a neighbor, was studying medicine, but had studied chemistry, and Edward thought he would like to follow the latter profession. In 1872 he was recalled from school to go to work in view of impending bad times which his father sensed. Dr. Otto Wuth of Pittsburgh refused to take the 16-year-old boy into his laboratory as an apprentice, because "there was nothing in chemistry." Ten years later substantially every iron and steel works in the district had its own corps of chemists.

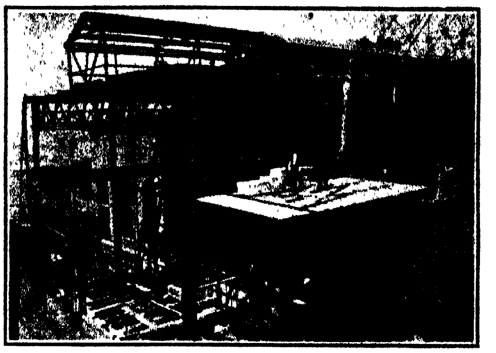
Young Acheson at 23 "took to" electricity, and at the end of a year, against all friendly advice, he came to New York. He spent weeks hunting a job and finally with money almost gone he landed as a draftsman in the Edison establishment at Menlo Park.

When work was slack in the drafting room he undertook to develop a notion he had of a new meter to measure currents. Mr. Edison came along and asked what he was doing. "I don't pay you for this," he exclaimed. "Suppose it turns out useful. Then if I adopt it you'll say I stole your invention!" "No sir," replied young Acheson. "I'm working here on your time and you pay me for it. Anything I bring out is yours!" And soon thereafter he was turned loose in the Edison laboratory.

A senior fellow-worker at the Edison laboratory was Dr. Edward L. Nichols, later of Cornell University. He had studied with Helmholtz and been a research fellow at Johns Hopkins. They took rooms jointly with a clergyman at Metuchen, 2½ miles away, and on their walks back and forth discussed physics and chemistry. Dr. Acheson got his scientific education through conversation with carefully selected friends and from directed reading. In the Romance of Technology our readers will find no more interesting chapter than the story of his career, of the inventions that resulted in carborundum, siloxicon, aquadag, oildag, and artificial graphite, and of the many distinctions and honors in science that have been accorded him.

Manufacture and Application of Lightweight Concrete Slabs

BY ALAN G. WIKOFF
Assistant Editor, Chem. & Met.



WHILE the setting of concrete involves complex chemical reactions, the process proceeds satisfactorily without chemical supervision, so that the production of cast concrete forms by a chemical company is at once an indication of some new or unusual feature. For some time the Porete Manufacturing Co., Newark, N. J., has been manufacturing, for construction purposes, concrete slabs containing so many air cells that their weight is only about one-third that of the corresponding solid slabs. The necessity for chemical control in this case arises from the method that has been devised for making the concrete porous.

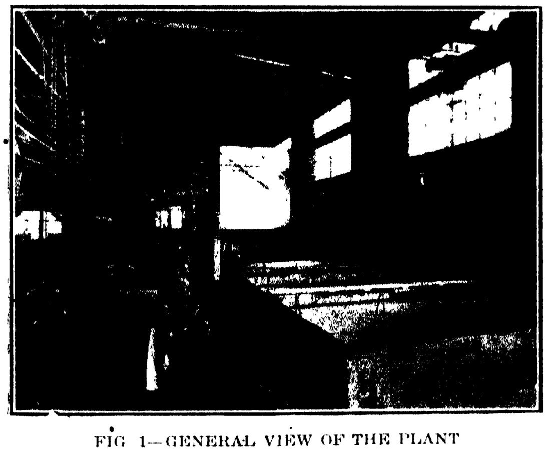


FIG. 1—GENERAL VIEW OF THE PLANT

A material that is solid at ordinary temperatures but melts easily in hot water is formed into round pellets about $\frac{1}{16}$ to $\frac{1}{8}$ in. in diameter, by allowing the liquid material to flow through a perforated plate into a tank of cold water. The pellets are discharged upon a screen to drain and when the requisite quantity has been prepared the screen is dumped into a mixer below. Cement and sand are added so that the final proportions are three parts of cement, one of sand and seven of pellets. After mixing thoroughly with a measured amount of water, the concrete is dumped into a hopper provided with a measuring device which delivers a uniform volume of concrete to the forms. These are of steel so constructed that they may be taken apart to facilitate removal of the completed slabs. Before filling, a piece of expanded metal reinforcing is placed in the form and supported evenly about $\frac{1}{4}$ in. above the bottom plate. After the concrete has been leveled off with a hand trowel the filled forms are placed in racks, where they remain until evening. In order to regulate the setting process, the racks are then placed in a tank of warm water over night. An electric hoist mounted as a traveling crane is used in handling the racks.

By morning the concrete has set sufficiently so that the slabs may be removed from the forms, which are then cleaned and made ready for further use. In order to render the slabs porous it is, of course, necessary to get rid of the pellet material, and since this is relatively much more valuable than the other constituents of the concrete, it is desirable to recover it as completely as possible. The combined step of removal and recovery is thus a very important part of the manufacturing process. The slabs are sealed in an oven which can be heated externally by a coal fire and which is also provided with connections for admitting steam to the interior of the oven. As the slabs warm up the pellet material melts and runs out through an opening in the bottom of the oven into a sump. The remaining pellet material is removed by introducing superheated steam, which carries the vapor through an outlet in the top of the oven to a water-cooled condenser. By means of an automatic temperature regulator it is possible so to condense this mixture of steam and vapor that the pellet material remains liquid and collects with the material already in the sump. The recovered material is pumped from the sump to the pellet-forming machine, thus completing the cycle.

Part of the building in which Porete is manufactured is shown in Fig. 1. In the right foreground are the tanks that regulate the setting of the concrete; back of these is the oven and to the left of the oven the condenser for recovering vaporized pellet material.

PROPERTIES AND APPLICATION OF PORETE

The finished slabs are 24x32x1$\frac{1}{8}$ in. and weigh about 30 lb., including the expanded metal, while a solid concrete slab of the same dimensions and com-

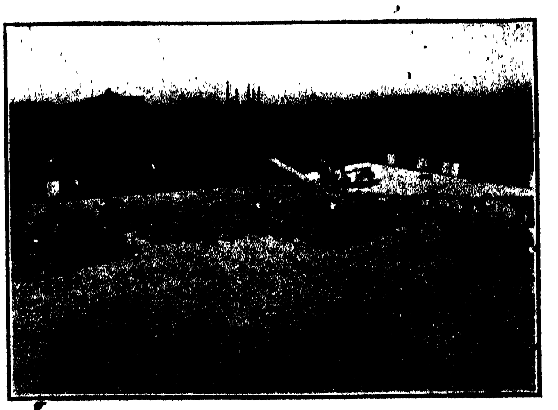

FIG. 2—ROOF CONSTRUCTION

FIG 3—PORETE ROOF FOR FOUNDRY

position would weigh about 75 lb. This is equivalent to about 55 lb. per cu.ft., or 6 lb. per sq.ft. of surface These slabs are admirably adapted for building purposes, for sidings, roofing or flooring, as they may be nailed directly to wood studs without injury, or clipped to steel beams or purlins. The side of the slabs which was in contact with the steel form is comparatively smooth and solid, whereas the other presents the appearance of concrete sponge. In construction work this porous side is kept toward the outside, thus furnishing an excellent base for the application of stucco. For roofing and flooring the surface is treated with a cement finish. Because of the light weight of this material the roof members of a steel frame structure may be of a much lighter construction than would otherwise be required.

Although light in weight, the slabs are very strong. They are designed like a reinforced concrete slab. The steel near the bottom takes care of the tensile stresses, and the cement finish that is applied to the top and makes a perfect bond with the rough surface takes care of the compressive stresses produced by the bending moment. In the way in which the slabs are used on roofs they will carry a live load of 40 lb. per sq.ft. (which is required by most building departments), with a factor of safety of over 6. In tests, specimens have broken at 300 lb. per sq.ft. on a 32-in. free span. Figs. 2, 3, 4 and the headpiece illustrate the use of Porete for roofing and flooring.

Because the slabs are reinforced with a surplus of steel, a greater amount of cement finish on top will increase their strength. For instance, in concrete floors, after a ½-in. thickness of cement is applied to the top of the slabs, this finish makes them strong enough to carry heavy floor loads of 125 lb. per sq.ft. with a factor of safety of 5, where beams are set on 32-in. centers. This gives a very lightweight, shallow and strong floor construction, especially valuable for mezzanine floors.

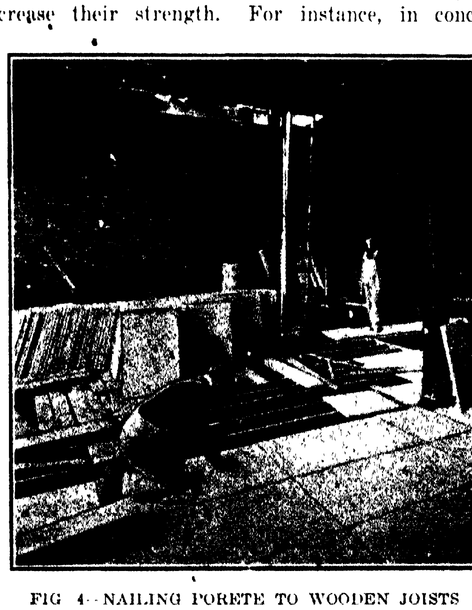

FIG 4—NAILING PORETE TO WOODEN JOISTS

On account of the cellular structure of Porete, it makes a much better heat-insulating material than solid concrete. Tests made by Lichtin[1] indicate that the heat-insulating value is about the same as that of wood. This is an additional feature which makes Porete desirable on roofs.

The saving in steel on account of the light weight of Porete is especially pronounced on a long span construction, and Porete roofs have been used and are in the course of construction on power plants, factories, public garages, theaters, schools, etc. The company expects soon to have other exterior building units, where light weight and nailability combined with weatherproofness are desirable features.

This material would seem particularly valuable in the construction of roofs and floors of large and small buildings around chemical plants, as the material is resistant to the effects of heat, steam and many chemical fumes. No interior finish is required, the slabs being simply nailed to wooden studs or clipped to the beams and given an outside coating of cement. The building in which Porete is made is an excellent example of this type of application. As will be noted in Fig. 1, the sides and roof are formed of Porete slabs clipped to a light steel framework.

For data used in the preparation of this article, the writer is indebted to Ernest Walter, vice-president of the company and inventor of the process, and R. D. Hudson, superintendent.

Action of Sulphurous Gases on Nickel-Chromium Alloys

In discussing alloys resistant to corrosion before a recent meeting of the Faraday Society, J. F. Kayser said that practically all manufacturers claim that their nickel-chromium alloys are quite resistant to the action of sulphur in furnace gases. He tested several such commercial alloys, and some would withstand the action of steam, carbon dioxide, carbon monoxide, ammonia and even pure oxygen for indefinite periods without scaling. Mixtures of those gases were also found to be quite harmless upon most of his samples. The introduction of either H_2S or SO_2—particularly the former—proved, however, to be fatal to even the highest grade nickel-chromium alloy.

Strong Bronzes

The Engineer notes in its issue for May 4 that the Brentford Foundry has produced a very remarkable bronze (or rather brass) called "coronium." Its composition is 80:15:5 Cu:Zn:Sn, and is apparently similar to the Oreide (80.5:14.5:4.85:0.1 Cu:Zn:Sn:Pb) noted in Professor Campbell's list of alloys, and is closely kin to screw brasses containing up to 1½ per cent lead. Sand castings have given 36,000 to 40,000 lb. per sq.in. breaking strength. Taking special precautions in pouring and cooling, specimens are reported having ultimate strength of 50,000 lb. per sq.in., elongation 38 per cent in 2 in., and contraction 37 per cent.

Manufacture of Activated Carbon

BY ARTHUR B. RAY
Union Carbide & Carbon Research Laboratories, Inc., Long Island City, N. Y

THE diversified and extensive industrial applications of activated carbon are causing this product to be manufactured in larger and larger quantities. The National Carbon Co., Inc., of Cleveland, Ohio, began in 1919 the manufacture of the type of activated carbon particularly suited for adsorbing gas and vapors, and also the types adapted for purifying and decolorizing liquids and catalyzing various reactions. At the present time it is the only concern in the United States producing all these types in commercial quantities. Several other plants are now engaged in making the type of activated carbon that is suitable only for purifying and decolorizing liquids. The demand for the gas-adsorbing type of activated carbon for use in extracting gasoline from natural gas, recovering solvents, abating odors, purifying gases, etc., is growing rapidly, because its relative commercial value in comparison with oils, cresols and other absorbents is becoming widely recognized. New commercial uses for this unique material are being found constantly, and it is predicted that in a few years many industries will consider it indispensable. The demand for the type of carbon used in purifying and decolorizing liquids is also increasing, as its relative efficiency in comparison with boneblack and fullers earth is gaining general recognition.

The many industrial applications of the new types of highly activated carbons recently made available indicate that the manufacture of these carbons is destined to be an important industry in the United States. There is, however, no one type of carbon that can be universally effective for all purposes. All so-called activated carbons contain more or less active carbon (which is regarded as a fairly definite physical entity), but they also have extremely important secondary properties of density, strength, hardness, etc. For industrial gas and vapor absorption, for instance, a granular activated carbon which is mechanically strong, relatively dense and highly active is required. The soft, finely pulverized, highly porous and generally moderately active decolorizing carbons are practically worthless for this purpose. In order to supply the carbons most effective for the different industrial applications the manufacturer must by proper selection of activating method and raw materials be able to control the activity and also the secondary properties such as hardness and density of his product.

Activated carbon is a comparatively new product. A number of so-called decolorizing carbons, which are carbons activated to some extent, have been on the market for several years, but the new and very different product now being produced and used commercially for gas and vapor adsorption was developed during the war in answer to the demand for a material of great adsorptive capacity for use in gas masks. The discovery of the fundamental factors involved in its production is without doubt one of the outstanding scientific achievements of recent years. But gas mask carbon, although more highly active than any carbon produced before its development, does not effectively decolorize and purify many liquids. The fundamental reasons for this and the essential characteristics of highly activated carbon which will most effectively decolorize and purify various types of liquids were later discovered, however, by the writer.

One distinction should be clearly made at the outset to avoid possible confusion. *Active* carbon, as will be seen in the subsequent discussion, is regarded as a fairly definite physical entity of well-defined properties. The so-called *activated* carbons of commerce are not pure active carbon, and may vary enormously in porosity or density, strength, hardness, etc., by reason of the associated inactive carbon structure. Yet upon these secondary and incidental properties may depend the commercial usefulness of the carbon for a given industrial purpose. It is now known that the carbon must not only be active but must also possess special physical and structural characteristics to make it effective for special purposes. There is no one type of activated carbon that can be universally effective for all purposes. Two activated carbons may contain the same percentage of active carbon, but one may be extremely valuable as a commercial vapor adsorbent, while the other, because of its low density, softness, etc., may be practically worthless for this purpose, though very valuable for decolorizing sugar solutions. Therefore the art of manufacturing activated carbon and its commercial possibilities depend as much upon the knowledge of how to control these secondary properties by proper selection of method and materials as upon the basic properties of the active carbon content itself. This fact should be kept in mind by prospective users of activated carbon.

In order that the discussion of the manufacturing processes may be clearer, let us first discuss in some detail the nature and chemistry of formation of active carbon and the structural characteristics of activated carbons.

The only theory of the nature and formation of activated carbon which satisfies the known facts is that given by Dr. N. K. Chaney.[1] According to this theory, active carbon exists as a distinctive physical modification differing from other known inactive forms of carbon by some characteristic peculiarity of molecular structure or arrangement. To this characteristic structure are attributed its special properties—namely, its unique adsorptive power for gases and vapors and, for certain substances in solution, its unusual chemical activity, and the limited temperature range of its formation. The nature of this physical or structural difference has been left to subsequent research for more complete definition. To quote the original paper: "It would be premature to assert that these two forms of carbon (active and inactive) are true allotropic modifications. It is not yet established that both forms are amorphous. . . . This much is established: The two forms are characteristically distinct and easily differentiated, both by their properties and conditions of formation." In the absence of direct evidence, the presumption

[1] *Trans. Amer. Electrochem. Soc.*, vol. 36, pp. 91-111 (1919).

of the theory has been that the active form would prove to be the simplest in structural form if not completely amorphous. Prof. Henry Briggs[1] has recently expressed the same underlying idea by referring to the active form as probably less highly "polymerized" and possessing interstices of molecular dimensions.

It has been experimentally demonstrated that the elementary carbon formed by the decomposition of carbon-containing compounds may exist in two forms—one of which is active and the other inactive. The temperature of carbon deposition appears to be the controlling factor—the carbon deposited below 500-600 deg. C. being active and that deposited above this temperature range being inactive. Carbon deposited by the catalytic decomposition of carbon monoxide by ferric oxide at 300 deg. C. is highly active. Also carbon deposited by the reaction between carbon tetrachloride and mercury[3] or sodium amalgam[4] at relatively low temperatures is active. On the other hand, the carbon deposited by cracking methane, for example, at high temperatures is inactive. It appears to be well established, therefore, that the temperature at which elementary carbon is deposited determines whether it is the active or inactive variety.

Applying this theory to the commercial preparation of activated carbon, it will be seen that the low-temperature carbonization of vegetable materials such as wood, nut shells, etc., would be expected to give a certain amount of active carbon. Why, then, does not ordinary charcoal exhibit the properties of activated carbon? The answer is that during the ordinary process of carbonization the active carbon formed adsorbs certain hydrocarbons and stabilizes them so that they are retained under conditions of temperature and pressure which would ordinarily decompose or eliminate them. This has been experimentally shown. The active carbon being already saturated cannot, therefore, exhibit any further adsorptive power. The term *primary carbon* has been applied to this complex of stabilized hydrocarbons adsorbed on an active carbon base. Ordinary vegetable chars, low-temperature carbonization cokes, blacks and coals belong to the class of primary carbons and from all these products activated carbons suitable for commercial uses can be prepared. On the other hand, cokes and other forms of carbon that are formed at high temperatures invariably consist largely of the inactive variety of carbon and cannot be activated.

STRUCTURE OF ACTIVATED CARBON

The adsorptive power or "activity" of an activated carbon is determined by the amount of available active carbon that it possesses. If an ineffective activating process has been employed or if the material has not been subjected to the activating process for a sufficient length of time the proportion of the active carbon present that is rendered available will be small and its "activity" and value as an adsorbent will be correspondingly low. These slightly activated products may contain a large percentage of carbon that has not been freed from its adsorbed hydrocarbons or they may contain inactive carbon that has been formed by the cracking of hydrocarbons at elevated temperatures. Activated carbons are evaluated by methods which really measure their *available* active carbon content.

To be effective as an adsorbent the active carbon must be exposed and accessible. All highly adsorptive activated carbons are therefore either highly dispersed or are traversed by innumerable canals or capillaries whose chief function is to permit free access to the particles of active carbon. The diameter of the submicroscopic capillaries in a highly activated coconut charcoal has been calculated from vapor pressure measurements to be of the order of 10^{-6} cm. These capillaries enable gas or vapor molecules to reach an enormous surface of active carbon—render it available. The surface thus rendered available per cubic centimeter of this carbon has been variously calculated to be from 120 to 1,000 sq.m. There are also in such a carbon many visible pores of relatively large diameter which merely act as outlet channels for the sub-microscopic pores.

When such a carbon is exposed to a high concentration of condensible vapor, a certain amount is adsorbed on the immense surface of active carbon exposed and a further amount is condensed in the capillaries of varying sizes. However, if such a carbon is exposed to a very low concentration of vapor, a considerable amount will still be adsorbed by the active carbon, but none will be condensed in the larger capillaries. This ability of activated carbon to take up vapors that are present in extremely low concentrations is one of its characteristics which distinguish it from other absorbents that are merely porous and whose adsorptive capacity under these conditions is very small.

Gas-Adsorbing Carbons—The desideratum for a gas-adsorbing carbon is that it shall have the maximum adsorptive capacity per unit of volume, rather than per unit of weight. This means that the largest *mass* of active carbon must be contained in unit space consistent with maintaining free access or passageway to all the particles in such mass. In other words, the carbon must not be too dense or its permeability is destroyed, and it must not be porous to the extent of needlessly sacrificing adsorbent material. If the density of the carbon falls below a critical minimum value, adsorptive capacity per unit of space begins to be lost. The best gas-adsorbent carbon is relatively dense. Activated coconut charcoal of maximum adsorptive capacity per unit of volume has a block density of approximately 0.66. A higher density than this indicates that the maximum surface is not exposed, and a lower density indicates that the carbon is traversed by larger pores and that the adsorptive capacity per unit volume is decreased. Aside from the proper size and number of pores is the question of mechanical strength. Carbons that are to be used for industrial gas and vapor adsorption must be mechanically strong in order to resist the crushing and abrading action to which they are usually subjected. Fortunately, the materials such as activated coconut charcoal and certain activated synthetic products which have maximum adsorptive capacity per unit volume are also mechanically strong and eminently suited to resist crushing and abrading action.

Decolorizing Carbons — Considering now activated carbons for use in adsorbing substances from liquids, we find that again the extent of the available active carbon determines the decolorizing or purifying value of the carbon. In the case of gas-adsorbing carbon, capillaries of almost molecular dimensions are desired to open up the active carbon, because the smaller the capillaries and the more numerous they are the greater the adsorptive capacity per unit volume of carbon. But in the case of adsorbing substances from liquids, in many

[1] *Proc. Roy. Soc.* (London), vol. 100A, pp. 88-102 (1921).
[3] G. Tamman, *Z. anorg. Allegem. Chem.*, vol. 115, pp. 145-58 (1921).
[4] B. Fetkenhuer, *Z. anorg. Allegem. Chem.*, vol. 117, p. 281 (1921).

instances the small capillaries which satisfactorily make available or open the active carbon for gases and vapors do not make it available for adsorbing colloidal materials or larger molecular aggregates. Presumably these small pores are plugged by such substances and so to all intents and purposes the active carbon which these pores expose is not available because it cannot be reached. The type of activated carbon that is most effective under these conditions is a highly porous material traversed by pores of relatively large size which render the active carbon available for adsorbing colloidal particles and large molecules. Such a carbon has a low apparent density and is more readily crushed than the dense gas-adsorbing type of carbon. Since this type of carbon is generally used in a finely divided form, its relative softness is not an undesirable property. Such a carbon, however, should not powder or "slime," because in this condition it cannot be readily filtered from the liquid. A finely divided "grainy" or fibrous carbon such as the carbon produced by the Chaney activation process from wood is not only a most effective adsorbent but an excellent filtering medium. While moderately bulky or low density carbons are desired, an extremely bulky carbon is undesirable, particularly in treating liquids which are to be saved, such as oils, because they entrain too much of the liquid.

It is evident that the structure of an activated carbon determines its value for a particular use. In the foregoing, the writer has pointed out some of the structural differences between the two general types of carbons. There are also many structural differences among the various types of gas-adsorbing carbons and among carbons that are intended for treating different liquids.

Processes of Manufacture

From the foregoing it is evident that in the manufacture of activated carbon a large amount of active carbon must be exposed and made available for adsorbing the desired substances. It has been shown that no one type of activated carbon can be made which can be used universally with high efficiency. It is further evident that raw materials and processes that are eminently suitable for the manufacture of highly porous finely powdered decolorizing carbons cannot be used with success for the manufacture of dense and mechanically strong granular carbons for the absorption of gases and vapors.

The raw materials available for the manufacture of activated carbon are, as previously indicated, various vegetable substances or chars prepared from these substances, coals or low-temperature cokes, and many other organic substances such as oils, gases, etc., which can be decomposed to give carbon. No matter what material is employed, it is essential that the carbon be deposited at temperatures below 600-700 deg. C. and that the adsorption of hydrocarbons by the active carbon be prevented or that the adsorbed hydrocarbons be eliminated in such a manner as to leave the active carbon base free. As has been explained, it is also essential that the activated carbon material have the proper physical characteristics. This is determined by the proper selection of raw materials and activating processes.

To prepare a material containing a high percentage of active carbon is a very difficult matter and it must be understood that not all processes in use are equally effective. Most of the older processes that have been suggested are for preparing decolorizing carbons from specially selected raw materials. These decolorizing carbons are classed as activated carbons, but many of them contain a relatively small percentage of active carbon and cannot compare in adsorptive power with the highly activated carbons now produced. Practically none of the processes or raw materials available for preparing highly porous pulverulent decolorizing carbons can be used to prepare highly active granular gas-adsorbing carbons. The processes by which various types of activated carbon can be made may be classified as follows:

(1) Processes depending on the action of inorganic chemical compounds either naturally present or added to prevent the formation of the adsorption complex during carbonization or to cause the breaking down and elimination of the adsorbed hydrocarbons during the succeeding calcination.

(2) Processes depending on solvents to eliminate the hydrocarbons.

(3) Processes depending solely on long-continued calcination to eliminate the hydrocarbons.

(4) Processes depending on selective oxidation to break down and remove the adsorbed hydrocarbons and to alter the porosity of the carbon.

Activation Processes Depending Upon the Action of Chemicals Naturally Present or Added to Raw Materials—By far the greater number of processes for producing decolorizing carbons that have been disclosed or patented belong in this group.[5] The raw materials employed in these processes are practically all of such a character as to give soft, highly porous products which contain some active carbon. The carbons produced by these processes have value for decolorizing liquids because of their very great dispersion, but because of their usual low content of active carbon and physical characteristics they are practically worthless for adsorbing gases and vapors.

In certain cases a raw material such as kelp[6] and rice hulls[7] contains a sufficient amount of the proper sort of substances to enable a decolorizing carbon of value to be prepared from it by a simple carbonization, calcination at high temperatures and subsequent purification.

In most cases, however, the raw material is admixed or impregnated with various chemicals. The disclosures in journal and patent literature show that the number of compounds that may be used more or less successfully in producing decolorizing carbons is large. The following may be mentioned: Alkali hydroxides, carbonates and sulphates; alkaline earth oxides, carbonates, chlorides, sulphates, phosphates and acetates; zinc chloride; manganese oxides; and phosphoric and sulphuric acids. Various proportions and mixtures of these chemicals are employed and to be most effective they must be mixed with the vegetable materials prior to their carbonization. The final calcination is in general carried out at temperatures around 900 deg. C. The residual chemicals must be removed before the carbon can be used, and in those cases where acid is required the extraction is costly. As a rule the raw materials are used in a finely divided form, so the final products appear in the form of a powder.

Activation Processes Depending on the Action of Solvents—Since the formulation of the activation theory previously discussed, suggestions have been made from

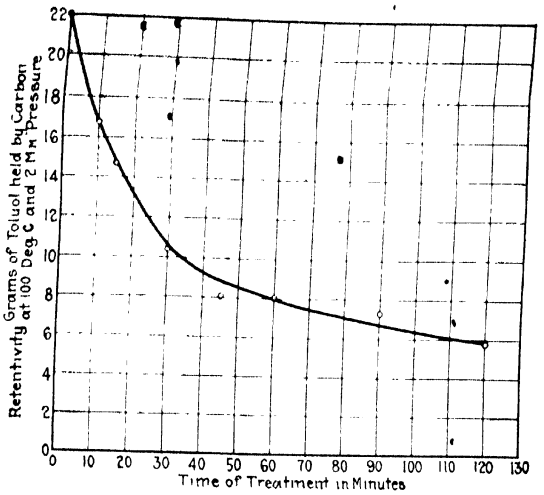

FIG 1—DEACTIVATION OF ACTIVATED CARBON BY "GAS TREATING"

Natural gas passed over activated coconut charcoal held at 1,000 deg C Retentivity for toluol taken as measure of activity

time to time that the hydrocarbons with which the active carbon base of primary carbons is saturated be removed by suitable solvents. All the various well-known solvents for resins, tars and pitches have been suggested. The use of selenium oxychloride for this purpose has been patented.[7] Even assuming that all the objectionable hydrocarbons are soluble in the special solvent, the trouble with these schemes is that no provision is made for removing the solvent which is readily adsorbed or for controlling the porosity of the carbon, both of which steps are necessary before the carbon can have any special value as an adsorbent.

Activation Processes Depending on Long-Continued Calcination at Elevated Temperatures—It is claimed that certain carbonization products or primary carbon materials may be partly activated by long-continued heating in a neutral atmosphere at temperatures around 850 deg. C. Our experience and the experience of others indicate that any activation obtained by such treatment is fortuitous in that it is largely due to the oxidizing action of air[8] originally held in the pores of the primary carbon or which enters the apparatus during the calcination. Activation by heat-treatment alone cannot be successfully accomplished because the hydrocarbons present are cracked at the high temperatures employed and inactive carbon is deposited upon the active carbon base. The resulting product has little or no activity. That active carbon is actually deactivated by a very slight deposition of inactive carbon upon it by the cracking of such a hydrocarbon as methane at 1,000 deg. C. is shown by the curve in Fig. 1. The activity of the carbon, which is measured by the amount of toluol held at 100 deg. C. and 2 mm. pressure, decreases as the amount of inactive carbon deposited increases and is practically nil when less than 1 per cent of inactive carbon has been deposited. This deposition of inactive carbon by the cracking of contained hydrocarbons when a primary carbon is calcined at high temperature is the fundamental reason, therefore, why the manufacture of a highly active carbon is a difficult matter.

Activation Processes Involving Selective Oxidation—Processes in which a selective oxidation is employed to render available active carbon initially present in the material treated are far superior to any other as yet developed for the preparation of highly activated carbons possessing particular structural characteristics. It is only by the use of such processes that it is possible, at the present time, to manufacture in quantity a carbon which meets the requirements of a commercial gas and vapor adsorbent.

It was this method of activation that was employed exclusively by the U. S. Chemical Warfare Service during the war and which made it possible for the Service to supply, in enormous quantities, a gas mask carbon which far surpassed in efficiency any that was available elsewhere. The process was developed under the stress of urgent war-time necessity by Dr. Chaney and those under his direction—an accomplishment all the more notable when it is considered that the United States was the last of the warring nations to be confronted with the necessity of an effective gas mask carbon.

Incidentally, the difference in the requirements of a carbon for decolorizing purposes and of one for gas adsorption is made strikingly apparent by consideration of the facts that while decolorizing carbons of fair quality had been made and sold before the war, these carbons were practically useless for gas masks, and the scientists of the other warring nations had been unable to produce modifications of them which were comparable in efficiency for gas mask use with the product of the Chaney process.

Fundamentals of Chaney Process

Dr. Chaney's contribution consisted essentially in an apprehension of the following fundamentals:

(1) Certain varieties of carbon are inherently inactive, and selective oxidation can be effective in causing activation only when applied to materials sufficiently free from the less easily oxidizable inactive carbon.

(2) A material amenable to activation by selective oxidation and free from inactive carbon can be prepared only if the carbon is liberated below certain critical temperature limits.

(3) A material containing active carbon is ordinarily useless as an adsorbent until this active carbon is freed from the hydrocarbons saturating it, and maximum adsorbing efficiency can be attained only when the maximum proportion of the active carbon present has been rendered available.

The principles enunciated by Chaney, and the process which he based on them, are the foundation on which has been built the National Carbon Co.'s output of activated carbon.

Despite the limitations imposed by the first principle, it was early demonstrated that the raw materials in which a sufficient amount of active carbon, sufficiently free from inactive carbon, was present or could be produced were more numerous than the materials that theretofore had been regarded as promising sources of gas-adsorbent carbon. It has further been found possible to produce superior decolorizing carbons from a variety of raw materials by employing the selective and limited oxidation processes which enable the dispersion or porosity of the activated product to be controlled. In fact all types of primary carbons may be activated by this general process to give many new and different types of activated carbons suitable for different purposes.

The primary carbons as defined by Chaney include all chars, cokes and carbon materials formed at low temperatures—below 600-700 deg. C. Vegetable chars, carbon blacks, lampblacks, low-temperature cokes and coals containing a small amount of volatile matter come under this definition. Some of these materials may be heated to temperatures above 700 deg. C. without be-

[7]V. Lehner and F. M. Dorsey, U. S. Pat. 1,423,231 (1922).

[8]Phillips et al., *J. C. S. Trans.*, vols. 117-118, pp. 362-699 (1920).

coming seriously contaminated by inactive carbon deposition as a result of "gas-treating." Other materials will become self-gas-treated if heated at a high temperature and then cannot be activated because selective oxidation will destroy the active carbon rather than the inactive carbon thus deposited.

When a gaseous oxidizing agent is employed, such gases as air, carbon dioxide and steam may be used. The process employing air as the activating agent has the advantage of relatively low-temperature operation—around 350 deg. C.—but the rise in oxidation potential with temperature is very rapid and the process is extremely difficult to control. As previously explained a *selective oxidation* of the residual hydrocarbons is desired. The oxidation by air, however, has been shown to be less highly selective and consequently, while a considerable amount of carbon is oxidized, the remaining carbon is only moderately activated. While the highest quality active carbon has not been produced by air activation process, an appreciable percentage of the carbon made by the U. S. Chemical Warfare Service for gas masks during the war was so activated.

Processes employing carbon dioxide or steam have the disadvantage of high-temperature operation—around 900 deg. C.—but these reagents exercise a selective oxidizing effect and the reaction, being endothermic, is readily controlled. Flue gas containing carbon dioxide has been used to produce some fairly well activated carbon, but after a very extended investigation it has been concluded that more highly activated carbon can be produced by steam activation. It appears also that the removal of the hydrocarbons with a minimum of "cracking" and consequent deposition of inactive carbon can be accomplished only when the concentration of the oxidizing agent is high. This means that the steam, for instance, must be introduced in excess and that the reaction products must be effectively led away. The operating difficulties are further increased by the fact that all primary carbon materials are very poor conductors of heat.

Variations in Properties

The great advantage of the Chaney process is that by employing proper steam rates for different periods, at selected temperatures, the characteristics of the activated product may be widely varied within limits depending upon the character of the primary carbon employed. This may be strikingly shown by data concerning the relative variations in properties of coconut charcoal activated under one set of conditions for various lengths of time. These data are presented graphically in Fig. 2. The variations in sorptive characteristics are shown by the curves marked "saturation" and "retentivity." To obtain the saturation value the carbon is dried, evacuated and then saturated with the vapor. This value, therefore, is a measure of the total sorptive capacity of the carbon when the vapor is held both by capillary condensation and intermolecular forces. When the saturated carbon is heated at 100 deg. C. while the pressure is reduced to 2 mm., the vapor condensed in the capillaries is largely removed and only the vapor is retained that is strongly held by the specific adsorptive power of the exposed active carbon. The weight of the vapor retained gives the "retentivity" or specific adsorptive capacity value. This value, therefore, is proportional to the active carbon exposed.

The curves show that the activation process proceeds

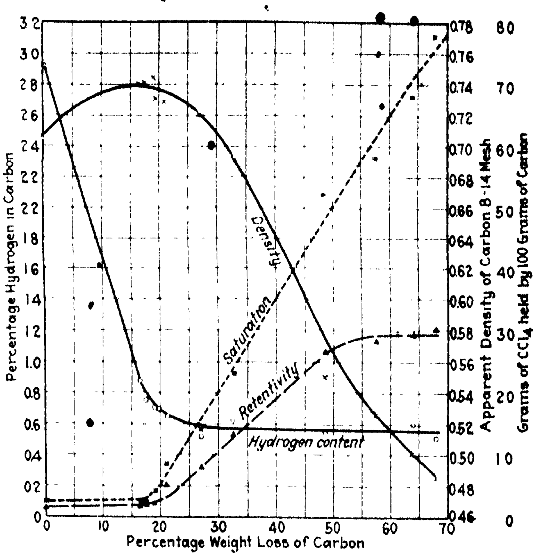

FIG. 2—VARIATIONS IN PROPERTIES OF COCONUT CHARCOALS ACTIVATED FOR VARIOUS LENGTHS OF TIME

Activation temperature, 1,000 deg. C. Weight of charge, 20 grams

in two distinct stages—viz., a stage in which the percentage hydrogen content is being rapidly reduced and a stage in which the percentage hydrogen content is being reduced very little or not at all. Approximately 20 per cent of the charcoal is gasified during the first stage. The material removed has an average percentage hydrogen content of 11.6 and is quite evidently hydrocarbons. Until the bulk of these hydrocarbons are removed the material has no appreciable saturation or retentivity value.

As the activation proceeds into the second stage, however, the material removed by selective oxidation has an average percentage hydrogen content of 0.78 and must, therefore, comprise a comparatively very large proportion of uncombined carbon and a comparatively small proportion of hydrocarbon. The fact that the percentage of residual hydrogen ultimately becomes approximately constant probably indicates that some of the hydrogen is disseminated through the active carbon base in such a fashion that it is not accessible to the oxidizing agent, as would be expected in dealing with particles of considerable size, in this particular case 8 to 14 mesh. During this stage both the saturation and retentivity increase, the saturation increasing at an approximately constant rate to the limit to which the tests were carried and the retentivity increasing at a diminishing rate to a maximum when about 60 per cent of the charcoal has been oxidized. The apparent density decreases at an approximately constant rate during this stage.

The saturation values in conjunction with the other values show that when the bulk of the hydrocarbons had been removed and the active carbon base was laid bare the capillary spaces began to increase at an approximately constant rate as the carbon was eroded by oxidation. Certain conclusions may also be arrived at from a consideration of the retentivity values in conjunction with percentage hydrogen content. The fact that the retentivity begins to increase while the percentage hydrogen content is still decreasing probably indicates that the layer of adsorbed hydrocarbons is not of uniform thickness, or not uniformly accessible to the oxi-

dizing agent. After the percentage hydrogen content becomes approximately constant, indicating that oxidation of the exposed hydrocarbons is complete, the retentivity continues to increase. The indications are that the phenomenon is due to an increase in the amount of exposed active carbon. The fact that the retentivity reaches a limit indicates that the amount of exposed active carbon per unit weight of material also reaches a limit.

From these considerations it is obvious that, to produce a carbon for use as a gas or vapor adsorbent having maximum adsorptive capacity per unit of volume, a dense primary carbon must be used, and the activation process continued only long enough to obtain a maximum of active carbon exposed. If, however, a highly porous carbon is desired for storing gases or for removing coloring matters and impurities from certain liquids, a highly porous primary carbon may be used and the activation continued only until maximum active carbon is exposed, or a dense primary carbon may be subjected to selective oxidation until it possesses the necessary porosity.

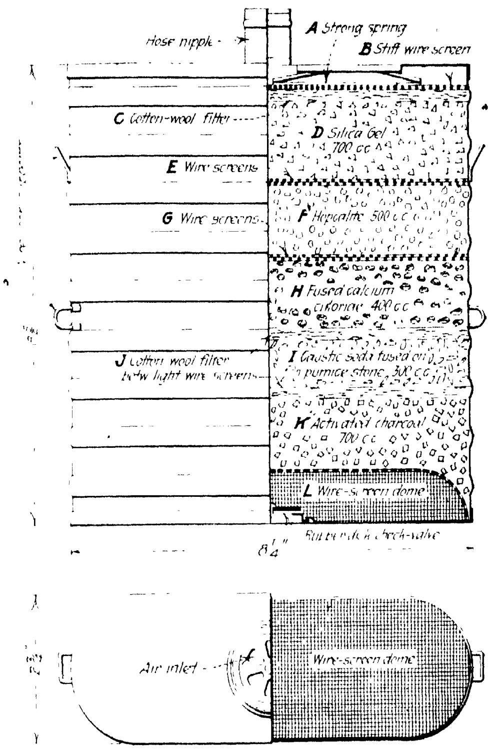
In the foregoing paper the numerous activating processes, most of which are for the manufacture of decolorizing carbons, have been considered. It is pointed out that the Chaney selective oxidation process appears to be the only one by which the new highly active and most efficient gas- and vapor-absorbing carbon can be produced. It is also shown that because this process gives maximum activity and allows the secondary properties, such as porosity, to be altered at will, it can be employed in the manufacture of decolorizing carbons of high efficiency. In fact, by activating suitable raw materials through some modification of the Chaney process carbons can be prepared that have the desired characteristics for any application.

Universal Gas Mask

Many Possible Uses for New Tpye of Mask Developed by Bureau of Mines

To fill the need felt for masks of general utility in the chemical, metallurgical and related industries, the Bureau of Mines has developed a new Universal mask. A special type of the same mask has been developed for use by firemen. Although special masks have been developed previously for use against specific gases, such as carbon monoxide or ammonia, this is the first efficient mask to be developed which may be used in either of these as well as in many other contaminating atmospheres. To combine efficiency in one canister the absorbents for all noxious gases is difficult, because the absorbents for certain gases are best used moist, while the absorbents for carbon monoxide may be used only when perfectly dry.

As shown in the cut, the following chemicals are used in the mask: *D*—Silica gel to remove ammonia and any other organic vapors which escape the charcoal at the bottom of the mask, also to guard against moisture reaching the hopcalite from above. *F*—Hopcalite to remove the carbon monoxide from the dry gas. *H*—Calcium chloride to remove any particles that may pass the caustic pumice. *I*—Caustic soda, on granules of pumice stone, to absorb acid gases such as carbon dioxide, chlorine, formic acid, hydrogen cyanide, muriatic acid gas, oxides of nitrogen and sulphur dioxide, and gases of similar chemical properties, also to extract



CROSS SECTION SHOWING CHEMICALS IN MASK

water vapors from the air, thus preventing the moisture from contaminating and inhibiting the hopcalite. *J*—Filter of cotton wool, about ¼-in. thick, between two light wire screens, to filter out the supensoids, including smoke, mist and dust. *K*—Charcoal, used to absorb organic vapors, including alcohol, aniline, benzene, ether, carbon bisulphide, carbon tetrachloride, toluene, etc.

In those industries in which a workman requires protection against only a single gas or class of gases, it would be cheaper to use a single absorbing medium in the canister. However, in many industries workmen may encounter a variety of gases and city firemen may meet almost any sort of gas or vapor. Men using the Universal type of mask can face these conditions and do work that they could not possibly do otherwise. Tests conducted on a wide variety of gases show that the probable life of a mask is considerably in excess of 6 hours, but, due to the fact that carbon monoxide may go through unabsorbed after this period and since this gas is not detected readily because it is odorless, this arbitrary time limit has been placed on the use of the mask.

Among the ordinary gases in which the mask is not efficient in protecting the wearer is methane. It cannot be used in atmospheres deficient in oxygen, as in the flues of industrial plants, mines and closed rooms after fires and explosions. It is also dangerous to use the mask in atmospheres containing higher concentrations of gases, as in chemical and metallurgical apparatus tanks containing gasoline or other volatile liquids or in inadequately ventilated rooms in which large quantities of gas are evolved. In general the mask should not be used in toxic gases having a concentration of more than 1 or 2 per cent. The canisters are more active when warm, so in cool or cold weather should be worn under a coat to receive the body heat.

Current Practice of Making Electric Steel

Best Practice Still Undecided on Many Features—Are Acid Furnaces Best for Low-Sulphur Charges?—Basic Will Eliminate More Sulphur, but Pure Raw Materials and Expert Refiners Are Necessary for Superfine Steel

BY BRADLEY STOUGHTON
Consulting Engineer

THE electric steel industry is not yet standardized: First, because progress is so rapid that it keeps ahead of the dissemination of information, which those who are doing the best work are not always willing to give out. Differences of opinion, due to lack of full knowledge, therefore, persist. A second cause is due to the fact that all recent improvements are not open to general use without royalty, and that conflicting claims are not always free from selfish interest. This is always the situation where an industry is so new that patents control some of the desirable features.

TYPES OF FURNACES

It would be impossible to give a description of all the recent furnaces now in use, but Table I classifies the types in accordance with the chief features, which vary largely in respect to: (*a*) Methods of heating the charge; and (*b*) methods of making electrical connection.

Method of Heating Charge.—It is obvious that electrical efficiency and endurance of the linings are both greatly enhanced when the charge is heated by virtue of its direct resistance to the passage of the current. Nevertheless the difficulties of accomplishing this, consisting chiefly of the difficulty of making the electrical connection and the inconvenient form of bath, have hampered the employment of this method of heating. From the metallurgical standpoint many advantages are obtained through the excellent stirring action caused by Dr. Carl Hering's "pinch effect," so extensively used in non-ferrous work. Therefore steel men earnestly desire a type of bath which can take advantage of this "pinch effect" and also be of convenient form. At the same time some means must be had of readily producing the carbide reaction $CaO + 3C = CaC_2 + CO$ without the use of an arc, since the carbide is so valuable both for desulphurizing and deoxidizing.

The direct arc from the electrodes to the metal or slag has proved more efficient economically and metallurgically than the indirect arc of the Stassano.

Method of Making Electrical Connection. — The method of introducing the current is the greatest present weakness of the electric furnace. The induction principle is ideal from the standpoint of current connection, but involves low electrical efficiency, serious lining difficulties, and inconvenient shape of bath. For these reasons it is less used. But the electrode principle is costly in design and operation, and metallurgically it introduces the complication of carbon in contact with the bath, which limits the field of application. I look to this feature (electrical connection) as the one most in need of improvement by invention of a radical character, such as the "ironless induction" principle, which, however, seems applicable only to furnaces of laboratory size.

The evidence is still conflicting as to the relative merit of passing the electricity through the hearth of the furnace. Undoubtedly it has many advantages over the exclusive use of suspended electrodes above the bath, and interesting claims are made about the operation of the new Italian Fiat furnace. But hearth troubles are serious enough without having electrodes imbedded in them, and the first prejudice is certainly against complicating this part of the furnace in any way. Nevertheless furnaces having electrodes buried in the hearth are being worked with great success where care and skill is exercised. Many persons have found less difficulty in power fluctuations when melting a cold charge on a conducting hearth.

Graphite vs. Carbon Electrodes.—The size of electrodes appropriate to the different sizes of furnace is now fairly well established, and the information is public. Graphite electrodes cost about twice as much as carbon electrodes per pound, but have greater conductivity per unit of area. The carbon electrodes have the further advantage that they may be made right at the furnace plant if desired. They are also slightly stronger, and their greater area increases the arcing surface. Their lower heat conductivity decreases the radiation loss through the electrodes, but increases the radiation loss through the roof on account of the larger hole necessary; this also weakens the roof. They are also more difficult to cool in the electrode holder and require a costly thread and nipple joint. Carbon electrodes oxidize more easily in the furnace and require heavier control mechanism. Their broken stumps are harder to remove from the bath.

It is still a good commercial operation where steel scrap and electricity are both very cheap and cast iron

TABLE I CLASSIFICATION OF ELECTRIC MELTING AND REFINING FURNACES

Method of Making Electrical Connection	Method of Getting Electricity Into Furnace	Method of Heating Charge	Name of Furnace

is scarce and costly, to melt steel scrap to a temperature of 1,400 deg. C. or higher, carburize it until it contains 3½ to 4 per cent carbon, and then give it the desired composition in silicon by means of appropriate alloys, especially where the metal from the electric furnace may be cast directly into molds. During the war there were many plants engaged in this process, making "synthetic cast iron" in France, Canada, United States and Germany. Most of these died with the change of commercial conditions consequent on the ending of the war, but there are still isolated localities where iron castings may be made in this way cheaper and better than by any other known method. A notable example is an iron foundry connected with a large gold mine in Alaska, where both fuel and cast iron are costly but where there is a supply of steel scrap. There are many mining localities in South America where the saving effected by a quick repair would exceed many times the cost and overhead of a synthetic cast iron foundry.

There were two methods of making synthetic cast iron—namely, straight melting in the electric furnace, and melting in a cupola followed by superheating in an electric furnace.

Order of Excellence in Steels

There is now a general agreement among engineers that the quality of carefully made steel by the different older processes is in the following order of excellence: First, crucible; second, acid open hearth; third, basic open hearth; fourth, acid bessemer; fifth, basic bessemer. Whether electric steel is equal to or subordinate in quality to crucible is still a controversial point.

The presence or absence of "sonims" (solid nonmetallic impurities) is the final test as to the supreme quality of steel, because all other impurities are controlled without great difficulty. The relative excellence of crucible or electric steel therefore comes to this: We know that well-made crucible steel is free from sonims; electric steel is not always so certain, although it should be, and almost always is, free from these impurities when well made. In the matter of large ingots the electric furnace has the advantage of making the steel in big units and doubtless gives a greater assurance of uniformity than when many crucibles have to be poured into one ingot mold. At the present moment conservatism and carelessness on the part of some electric furnace operators leave the advocate of the crucible furnace in the stronger position of the two.

From the standpoint of excellence—that is, very low content in phosphorus, sulphur, sonims and gases—the basic-lined electric furnace has the better of the argument with the acid electric. But, from the standpoint of "superexcellence"—that is, absolute freedom from gases and sonims the acid process has these points in its favor: (*a*) Pure raw materials must be employed, and pure raw materials are essential for the production of "superexcellent" steel in any type of electric furnace; (*b*) the slag also is purer; (*c*) recarburizing in the acid furnace is less likely to produce sonims than in the basic furnace.

On the other hand, the acid slag is subject to great viscosity, which introduces a serious danger of sonims, while the basic slag is the better degasifier of the two. Skill and care in operating are doubtless much more potent factors for superexcellence than either set of advantages mentioned. For example, merely to pour electric steel out of the furnace introduces far more sonims than any factor mentioned so far. Indeed, it seems fair to declare that "superexcellent steel" cannot be made unless the metal is tapped from a quiet bath without slag being carried with it.

Super-Refining Liquid Steel

The cheapest method of making steel of very high quality is to put liquid steel in an electric furnace and then super-refine it. Since the super-refining is chiefly for the purpose of eliminating sonims and gases, and since the electric furnace is not adapted to much refining in one step, the acid electric furnace might be used. It has the advantage of affording a quicker and cheaper operation, but the acid slags are very sticky and they will not hold calcium carbide, which is the most effective agent for desulphurizing and degasifying a steel bath. True, the acid process can remove a little sulphur by the judicious use of manganese, but the amount is limited and is usually less than must be eliminated from liquid steel coming from other furnaces. For instance: the upper limit of sulphur in molten steel introduced in even the basic electric furnace is now 0.08 per cent and this sometimes requires two carbide slags before it is reduced to 0.03 per cent, which is the maximum sulphur expected in an electric furnace product. Super-refining is the ideal function of the electric furnace; when we try to accomplish the ordinary operations of refining or even attempt too big a step in super-refining the result is excessive cost and poorer quality. The lesson of recent electric furnace experience is that we can add only the top notch of excellence; if we start with too low purity of raw material, the highest quality is never attained.

One of the worst problems in super-refining practice still remains to be overcome. I refer to the chilling of the liquid metal when poured into the furnace. Following the preceding heat the roof and lining must be examined and repaired carefully to avoid costly troubles from these sources. As an average figure it will perhaps take 500 lb. of dolomite to repair a 25-ton furnace lining, although this figure will vary greatly from operation to operation and plant to plant. This repair work takes time and cools the furnace. The metal from the basic open hearth also cools in transit. Furthermore its melting point is relatively high, because it must be 10 to 25 points lower in carbon than the desired final analysis of the super-refined product, to allow for carbon picked up from the carbide slag. The arc furnace is not a good instrument to handle a bath of metal frozen on its surface and especially along the sides, where it is furthest removed from the source of heat. Here again some means of keeping the bath stirred would be of great commercial advantage. Twenty to forty minutes on power are usually required to recover the lost heat.

Another serious difficulty is to estimate exactly the weight of metal charged to the furnace. This information is important in order to determine the weight of additions for "recarburizing." When nickel steel is being made the established practice is to add a known amount of nickel to the bath as soon as charged. As soon as this is all melted the analysis of the bath, compared with its composition before the nickel was added, gives a close means of estimating its weight.

Recent electric furnace practice retains at least 0.20 per cent manganese in the bath throughout the operation. This decreases the burden of the slag while deoxidizing the bath and reduces the final manganese addition, with its concomitant danger of sonims. It is

the costly metalloids. From ½ to 3 per cent of carbide should be maintained in the slag. As soon as a pool is formed, coke is shoveled into the furnace, and more is used when necessary. Greater precautions are observed in keeping the doors closed and luted than in super-refining liquid steel, and it is usual to scatter coke dust over the top of the slag whenever the door is opened. While the addition of coke to the slag will reduce manganese or chromium back into the metal, in case any has been oxidized, it requires both coke and high temperature to reduce tungsten.

There is this important difference between the two types of super-refining: That the carbon in the steel produced from liquid charges is usually lower than that in tool steel made by melting scrap. Therefore coke may be more freely used in the latter. Also it is much commoner and safer to add silicon in small doses in early stages of the practice we are now discussing, especially when tungsten is present, because tungsten serves as a warning preceding slag difficulties that might arise from oxidation of silicon. Silicon in the bath during super-refining assists degasification and makes the steel sounder and denser The amount of slag is greater in this type of super-refining, and varies from 3 to 7 per cent of the weight of the metal. Its composition is about the same, except for higher carbide. It should not exceed 18 to 20 per cent silica, and some operators prefer to use chiefly fluorspar for thinning, in order to increase the excess of lime present. Then, however, volatile fluorine compounds increase the corrosion of walls and roof.

In the basic electric furnace a good operator can melt and super-refine pure scrap in 4½ to 6 hours, with a power consumption of 600 to 800 kw.-hr. per ton of product. The main reason for the excess power consumption over liquid-steel super-refining is that great power irregularities occur during melting. Furthermore, smaller sized furnaces are ordinarily used, together with a larger slag volume.

Acid Versus Basic

In melting pure stock in the electric furnace the basic process loses its chief commercial advantage—viz., low cost of raw material. In every other respect—labor, time, electric power, overhead, repairs, lining, fluxes and recarburizers—the acid process is cheaper. The acid furnace is handicapped in removing sulphur, but a liberal use of manganese will bring it down quite a little, and the difference in cost is not great between 0.04 or 0.08 per cent sulphur scrap pure in other respects. It is now customary to use one acid slag for more than one operation, because impurities do not accumulate in it. No ferrosilicon is added, because silicon is reduced from the slag. This saves cost and the danger of silicon sonims. Acid steel is less oxidized and less gasified than basic steel after melting, so less manganese is used. The sticky acid slag is more easily entangled than are basic slag particles, but the more subtle danger of silicon or manganese sonims is greatly reduced. Finally, the engineers' prejudice in favor of acid steel helps sell the product in competition. The acid furnace has the disadvantage that it cannot be used on occasion for purifying impure scrap unavoidably accumulated or available under advantageous conditions.

Melting and Refining Impure Scrap

As ordinarily conducted this process is cheaper than melting and super-refining pure scrap, but gives a product of lower grade. Of course, only basic furnaces can be used. Even then the phosphorus must be under 0.09 per cent or the oxidizing period will be extended beyond the point of economy. Limestone, instead of lime, is spread on the hearth. Sometimes pig iron is used to make the bath melt down hard or to increase the yield by using more ore; if so, the pig is placed on top of the limestone. On top of this is placed enough iron ore to oxidize the silicon and phosphorus, and these should be gone by the time the "lime comes up." The temperature of the bath should never reach the point where manganese or carbon are oxidized instead of phosphorus. Good modern practice produces a melted bath with residual manganese, carbon 10 to 25 points less than the desired final analysis, phosphorus less than 0.02 per cent. Some prefer to melt down soft and, when the white slag is melted, add carbon in the form of pig iron, washed metal, coke, charcoal or ground electrode stumps. This stirs the bath, removes dissolved oxygen and increases the yield slightly. It is both difficult and dangerous to make low-carbon steel by this process, because some carbon is always added from the carbide slag, and if you melt down very soft it oxygenates the bath severely. In case a second black slag must be used it is evidence of bad practice or too impure raw charge. Every pound of black slag must be removed before the white slag is charged.

The white slag is mixed outside the furnace, of lime, fluorspar, silica, and coke. It contains more than 55 per cent lime and one shovel of coke to three of lime. After it is charged the analysis is adjusted carefully, the temperature being raised as rapidly as possible meanwhile. If carbon is added, it goes in first, then enough ferrosilicon to give 0.10 to 0.20 per cent of silicon in the metal, which is maintained to the end. Next comes ferromanganese, if necessary. Some operators prefer to melt down with only a small residual manganese, in order to add ferromanganese after ferrosilicon, with the object of removing silicon sonims. Others add ferromanganese after the deoxidizing slag has become white, thus saving some manganese. All additions made after the white slag should be in small doses. The more oxidizable elements, such as tungsten and vanadium, should never be added until the slag is entirely white. When this point is reached the real super-refining begins; more coke and lime are added to the slag and a carbide slag with at least 1 to 3 per cent of CaC_2 content is maintained to the end. The operation is practically the same as that already described.

The total time of melting, refining and super-refining occupies from 4½ to 7 hours, depending on the degree of purification and the skill of the operator.

Aluminum Production

The value of the new aluminum produced in the United States during 1922 is reported as $13,622,000, an increase of about 25 per cent over the value in 1921. Exports of aluminum during 1922 included 1,538,079 lb. of ingot and scrap aluminum and alloys containing aluminum, 2,808,946 lb. of plates, sheets, bars, strips and rods, and 4,548,939 lb. of manufactured articles, which represents a very large increase over the amount exported during the previous year. Imports, on the other hand, also increased to 31,482,983 lb. during the early part of 1922, as compared to 26,177,852 lb. for the corresponding period in 1921. This amount includes aluminum in crude form, scrap and alloys of any kind in which aluminum is the material of chief value.

Meeting of the Iron and Steel Institute

Committee Reports Against 12-Hour Day—Papers on Chemistry in the Iron and Steel Industry, Gas Producer Operation and Firebrick Disintegration

After a year's consideration, a committee composed of the chairmen of the large steel companies has presented a preliminary report on the 12-hour day. Judge Gary read its findings at the opening of the Iron and Steel Institute in New York, May 25.

The report stated that the problem was taken up because of the widespread impression that long hours in the steel industry were undesirable and injurious. Despite the opinion held by the committee that this sentiment was kept alive not by the workmen themselves but by outsiders, a careful investigation was made. In the light of the information obtained the committee reports that the 12-hour shift is not injurious to the worker, physically, mentally or morally—in fact, it believes that the managers of important plants generally have the workers' welfare so much at heart that such influences would be quickly detected and corrected. The committee believes, in fact, that the laborers would rather work 12 hours and earn the extra money, since the intermittent nature of their duties requires less total exertion than an 8-hour shift in many other trades.

Intricate economic questions also have a great bearing on the decision. In view of the demands of commerce, local and international, it is necessary that a great amount of iron and steel products be created at the lowest possible cost. The short shift would derange this desirable state of affairs by increasing the selling price about 15 per cent. Furthermore 60,000 additional employees would be needed, but could not be found—in fact, there is a serious labor shortage at the mills now.

While the 12-hour day can gradually be eliminated during periods of large labor supply, the committee, having in view the sentiment of the employees, employers, purchasers and general public, cannot now recommend the abolition of the 12-hour day, but promises that it will be done should the general public and the laborers concerned demand it, and purchasers of the metal become willing to pay the advanced cost.

Gary Says European Common People Are War Weary

Judge Gary, the president of the Institute, then continued with his formal address. For the most part it consisted of an account of a recent tour throughout the Near East, and a religious homily inspired by the devout, industrious and war-weary people he saw there. His audience revived its interest when he mentioned the Ruhr. Without commenting on the political situation involved, he deplored the appalling damage caused to both sides and to neutrals. He felt that the common people in France, Belgium and Germany would be very glad to break the deadlock, and that speedily. Perhaps the submission of the dispute to a neutral nation or jurist as arbitrator would be the best solution.

Before reaching the usual business survey, in which he could see no reason to doubt continued operations at capacity for the next 6 months, Judge Gary's voice and strength broke, and he was forced to ask another to continue the reading, meanwhile leaving the rostrum.

In the forenoon session, a brief account of the utility of chemical analysis was given by W. A. Forbes of the U. S. Steel Corporation. He pointed out how raw materials are selected and how furnace operations and products are controlled by repeated analyses. Since smelting and refining operations are essentially chemical reactions occurring at elevated temperatures, modern practice owes much to the rational application of chemical theory. "The electric furnace process could not have been developed without it, since this process involves a more scientific application of chemistry than all other steel processes combined." Recognizing that variations in steel quality are caused by small amounts of dissolved gases or chemical compounds which at present cannot be isolated or determined, the speaker asked the question, "How may further progress in the application of chemistry to the iron and steel industry be maintained? The answer is: In untiring and unremitting research."

Bradley Dewey, of the Dewey & Almy Chemical Co., in commenting on the foregoing paper, stressed the fact that general chemical theory should be of greatest aid to the steel industry of the future, which will require a great number of men of vision and scientific training to correlate existing data from many fields. After mentioning the tremendous success that has followed the introduction of physical metallurgy to the study of alloy and special steels, he predicted an entirely new metallurgy, with its host of new problems, when oxygen gas may be had for less than $5 per ton. He ventured even to predict a sizable tonnage of iron, coming as a byproduct from nitrogen fixation processes.

Gas Producer Operation

Waldemar Dyrssen, of the U. S. Steel Corporation, presented a voluminous study of "Gas Producer Practice." He had long been aware that the equilibrium diagrams between hot carbon, air and steam, determined in the laboratory, were inapplicable to gas producer studies, simply because gas rushes through the hot fuel bed so rapidly that the time element is lacking. So he attacked the problem from the other end. Possessing detailed studies of a number of producers, he worked back to what might be called the kinetic equilibrium of the producer. From such derived data he was able to draw most useful conclusions regarding all factors playing a part in coal gasification. He was also able to determine the optimum temperature of blast and gas. He showed that it is possible to control operations closely by merely regulating the temperature in the gas main. Ordinary bituminous coal when treated properly will produce the following gas: C_2H_4, 0.6 per cent; CH_4, 3.6; CO, 29.1; H, 13.3; CO_2, 3.4 and N, 50.0 (exclusive of H_2O and tarry vapors).

Disintegration of Firebrick

After an examination of the shattered firebrick in a blast-furnace lining, C. E. Nesbitt and M. L. Bell, research engineers of the Carnegie Steel Co., concluded that disintegration was due to reactions between Fe_2O_3 in the brick and CO in the furnace atmosphere. Reaction at 325 to 525 deg. C. is fairly rapid, depositing voluminous graphitic carbon, which bursts the brick into many pieces. It is apparent that a brick very free in ferric oxide should be used for blast-furnace linings—to test this point samples may be heated for 6 hours at 450 deg. C. in an atmosphere of CO. If the brick remains intact, it will not disintegrate from carbon deposition; if the sample breaks during the test, such brick should not be included in the furnace lining.

How Does Production Affect Profits?

Above a Given Production Value the Total Profit on a Commodity Becomes Less—Below That Value the Total Profit Has Not Reached Its Maximum—This Article Discusses Both Why This Is So and How the Optimum May Be Determined

BY WARREN K. LEWIS
Consulting Chemical Engineer and Professor of Chemical Engineering at M. I. T.

IN THE operation of manufacturing plants it is a principle thoroughly appreciated that production should be forced to the utmost limit not inconsistent with efficiency in manufacture and with the disposal of the product. This principle is sound, but its formulation is indefinite and vague. The object of this discussion is to develop an exact criterion for the application of the principle, in order to make it more useful in the control of industrial practice.

As the basis of the dicussion there will be assumed a definite plant producing one specific article. It will be granted that the plant is operating on a definite schedule and is being managed in the most efficient possible way. In the control of such a plant there is, however, one variable of paramount importance which can be effectively manipulated by the management—namely, the production to which the plant is forced. The object of discussion is to determine the optimum production at which the plant should be operated.

The novice in managerial work is prone to focus attention solely upon methods of reducing costs. It is often more effective to develop methods for wisely increasing costs. An improvement in production method resulting in reduced cost should be forced, often to the point where cost is actually increased, because by so doing production can be increased to more than compensate therefor.

In any plant unit costs can be subdivided into three major categories. The first of these can be designated as organization costs. The existing plant and physical equipment represent an investment on which a return must be paid. Furthermore, in order to operate the plant on any scale commensurate with its capacity, there must be maintained a personnel for management and supervision, which, though nonproductive, is a prerequisite to production. The cost of maintaining this whole organization, including both physical equipment and directive personnel, represents an unavoidable expense, which remains practically constant so long as operation is kept up. All changes of this description should be grouped together as *organization costs*. Such expenses are obviously made up of investment charges, taxes and insurance, include management and superintendence, and perhaps, in some cases, office expenses, and the like.

The second category is best described as *production costs*, and consists of items of which usually the major are labor and materials, charges that are practically proportional to the production of the plant regardless of the rate of production.

Finally, in the third category, which will be called super-production costs, fall a series of charges that increase more rapidly than production. Among the most important of these are depreciation, maintenance and repairs. In a plant that is running at a low production these items can, with careful management, be kept down to a very low figure; even when expressed as unit charges per unit production the figures will be moderate. When, however, it is attempted to force plant and processes, the wear and tear thereon increase and the upkeep expenses mount out of all proportion to the production. To the items enumerated above, there should be added in this third category those charges covering the decreased efficiency of labor that always results from forced production. For example, losses due to rejections of product upon inspection are of this character. In some cases, these last items are of paramount importance. (One of the advantages of the piece price system lies in the fact that the exact cost of securing increased productivity of labor, whether through the production bonus or otherwise, can so readily be determined.)

It will, therefore, be tentatively assumed that charges can be distributed among these three categories: organization costs, production costs, and super-production costs.

If in a given plant the production be small, the unit costs will be high, because the organization costs are distributed over a small production. With increased production the organization costs are distributed over a wider area, and the unit costs go down accordingly. But if production be carried further, the influence of the super-production costs referred to above will become evident, and the inefficiency of production caused thereby will tend to compensate for the lower organization costs per unit production. Thus costs will no longer decrease with further increase in production. Indeed, if production be forced to a still further degree, costs will actually increase. As a result of these relationships the cost of production in any plant is determined by the total production of that plant, and furthermore, with increase in production the cost curve first decreases rapidly, then becomes constant at a minimum cost, and finally increases due to the action of super-production costs. While the cost curves of no two plants and no two products will be the same, the general shape of these cost curves is always that outlined above, and is shown graphically in Fig. 1.

Tentatively assume that the product discussed above is one that is sold on specification. Then the quality of that product must be maintained up to standard in order to move it, but need not be pushed above the standard. Assume, furthermore, that the plant in question produces such a small fraction of the total consumption of its market that any variation in its own pro-

duction does not appreciably affect the price in that market. In such a case the selling price of the product will be a constant quantity, independent of the production of the plant.

The profit per unit product is obviously the difference between the selling price and the cost, it being assumed either that the costs mentioned above are the true total costs including the selling expenses, or else that the selling price is net selling price—i.e., total price less the selling costs. (This alternative should be adopted only when the product is sold by an outside organization at a fixed figure—e.g., on a commission—because selling costs, like all costs, fluctuate with the value of product handled.) The profit per unit product will, therefore, be determined by the production of the plant, the curve being of the shape of the cost curve upside down. These three curves are indicated in Fig. 2.

The total profit from this plant is obviously the unit profit times the total production. Inspection shows that the unit profit curve passes through zero at the two points where the cost curve cuts the selling price curve. Since the total profit is the product of unit profit times production, the total profit curve must also pass through zero at the same points. It is evident also that the general shape of the total profit curve must be similar to that of the unit profit curve, and since it starts from and returns to zero, the total profit curve must at some intermediate point reach a maximum, and this maximum is the point of optimum production at which the plant will earn the largest possible return on the investment and profits for the management.

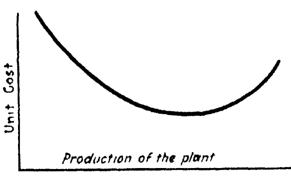

FIG. 1

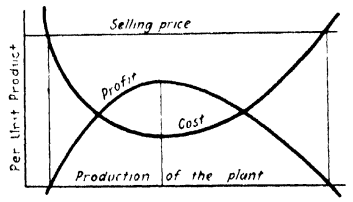

FIG. 2

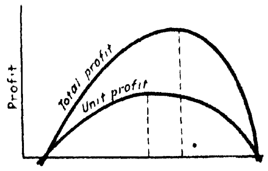

FIG. 3

Total Profit and Unit Profit

It is obvious that, for the case assumed, the unit profit curve goes through a maximum at a production corresponding to the minimum of the unit cost curve. At this maximum point, however, the unit profit curve is flat. This means that, if at this maximum point the production be slightly increased, the unit profit does not appreciably decrease. The product of unit profit into production must, therefore, increase. The consequence of this is that at the point of maximum unit profit the total profit curve—i.e., the product of total production into unit profit—is still increasing, and therefore the maximum of the total profit curve must lie to the right of that of the unit profit curve. (Fig. 3.) If, therefore, production be forced beyond the point of maximum unit profit, total profit will be increased. Inasmuch as the plant should be operated at the point of maximum total profit, this means that the plant should be forced at the sacrifice of an increase in unit cost in order to realize the maximum return.

This relation between cost and production is the key to the whole situation. It means that low costs of production are not a sufficient criterion of efficiency in plant management. A properly run plant can always reduce its costs by reducing its production, but thereby it would also reduce its profits. A management that is too anxious to keep costs down is likely to err in this regard, especially during periods of high prices. For example, during the early years of the war prices were so high that almost any increase in cost which brought about an increase in production was justifiable, because the increased production overbalanced the increased cost. Production costs must be scientifically adjusted to correspond with the market of the product.

Production costs are often used as a basis of judging managerial ability. This is peculiarly unfair, because the truly efficient manager will have higher production costs than the man, with equal technical ability, who is striving for low costs without an appreciation of the importance of a proper balance between costs and production. A direct comparison of the production costs of two plants or departments is inadequate and inconclusive. Efficiency in plant management will result in a low cost *curve*, but the more efficient of two plants may necessarily run at a production cost which is actually higher than that of the other. This fact is largely overlooked by industry.

With a variation in selling price the height of the unit profit curve changes, and the shape of the total profit curve is also modified. With increased selling price the unit profit increases and the total profit curve is bent toward the right so that the maximum point of the total profit diagram is forced to a point of higher production. With decreasing selling price the opposite is true—i.e., the maximum of the total profit curve not only decreases but also moves toward the left.

Two special cases are of interest. First, let it be assumed that selling price falls to such a point that it is exactly equal to the minimum cost of production corresponding to the lowest point on the unit cost curve. In such a case the profit is negative in value, except at a production corresponding to the minimum of the unit cost curve, at which point the unit profit becomes zero. If the total profit curve be constructed (Fig. 4) it will also obviously be negative at all values except at this same point, where it will have a "maximum" as before, but this "maximum" will be zero profit. Obviously, therefore, the plant under these conditions should be operated at the point of minimum cost, because at this point no money is being lost, whereas at any other production a loss will be sustained.

If the selling price be further reduced, the plant must obviously run at a loss. The unit profit curve (Fig. 5) is still the difference between the cost of production and selling price, but is now negative—i.e., becomes a unit loss, throughout its extent. The total profit curve also becomes negative—i.e., represents a loss—but it still has the same general shape as before, and still has a highest point, if considered as a profit, and a lowest point, if considered as a loss. This point will lie to the left of the point of lowest cost of production, and, if the plant be operated at this production, the loss on

the plant will be a minimum. Obviously this is the point of best economic operation.

Evidently a plant will not operate under such conditions except in the following cases: The first case is when the management feels that there is reasonable expectation of a future increase in selling price so that the plant will again produce a profit. The other exists when the total cost includes fixed charges which, though entirely legitimate because they represent an earning capacity of the money invested which can be realized in other similar lines of business, must be sacrificed because liquidation of the business would involve a loss in capital so great that the total return in interest on the capital salvaged would be less than the money actually earned for interest charges by the plant as it stands. Such conditions, however, so frequently prevail that the criterion outlined above for determining the best operating conditions is usually applicable.

It is not intended to intimate that these curves should be used as a rigid criterion of production. Labor conditions, future prospects of the market, the situation with regard to raw materials, and the like, are factors of paramount importance in determining modifications of production policy. On the other hand, the curves outlined above serve as an indication of the direction in which production should be modified, and of the extent to which it is desirable to go.

For example, in the case of a plant operating at a loss because of selling prices falling below the minimum cost of production, it is usually stated that the reason for maintaining operation is to keep intact the managing organization, and to keep available the labor for future expansion. This is quite true, but it is also true, as above demonstrated, that there is a definite production condition to which corresponds a lowest loss at which the plant can be run, and obviously under such a market situation this minimum loss should, if possible, be realized.

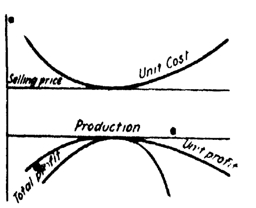

FIG. 4

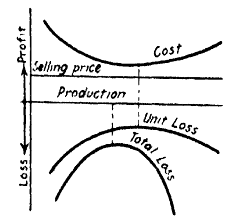

FIG. 5

Furthermore, this minimum loss can easily be realized without materially interfering with the maintenance of an organization and a suitable labor supply, because, under such conditions of manufacture as here assumed, it is usually possible to control the labor supply within wide limits by modifying the total hours of labor, and to maintain as a working organization the most desirable individuals to serve as a skeleton for future development.

The above discussion has been based on the tentative assumption of uniform selling price under given market conditions; this assumption, however, is in nowise necessary to a utilization of the curves and of this method of analysis of production costs, but was adopted solely to simplify the first presentation of the concept. Usually with an increased output the selling price of the product decreases more or less rapidly, due to the increased supply on the market or to a tendency of the product to fall in quality with increased production. In other words, the selling price curve assumes the shape indicated in curve *A*, Fig. 6. This modification of the selling price curve will somewhat modify the general shape of the unit profit and the total profit curves. A marked increase in production may result in a price curve of type *B*, involving the necessity of sharp decrease in price in order to open up new uses and markets to absorb the increased supply of the material. The maximum of the total profit curve is still the point of optimum production, and, in general, the selling price curve is sufficiently flat at the point of minimum cost of production so that the maximum point of the total profit curve lies to the right of this point. This is always true in a properly designed plant—i.e., in a plant the size of which is properly adjusted to the market for the product. Unfortunately the war placed many plants in the wrong category.

In using these curves, construction of the unit cost

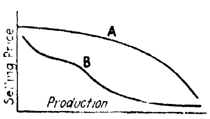

FIG. 6

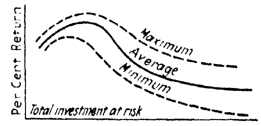

FIG. 7

curve as a function of production is the first essential point. The cost curve must in general be estimated, because it is not usually practicable to determine actual points thereon by arbitrary modifications of production. The estimation of this cost curve becomes relatively easy, however, if the production analyst will rearrange and reclassify, along the lines already described, the data available in the cost department. To make the classification and interpretation of these data reliable, the analyst must secure the close co-operation and advice of the cost department and especially of the operating engineers, because the data for any given plant can be interpreted correctly only in the light of a clear appreciation of the conditions and methods of operation in that individual plant. Subdivide costs into organization, production and super-production costs. The operating department can give a reasonable estimate as to the change of the last with increased or decreased production, and this rate of change of super-production costs with production is the only item seriously influencing the shape of the cost curve which it is difficult to estimate. The point on the cost curve corresponding to actual production being definitely and accurately known, it thus becomes possible to get a close estimate on the costs for any other production which differs not too greatly therefrom.

In determining the distribution of special items of cost the decision must depend upon the influence upon these items of change in production. For example, while raw materials almost always fall under production costs, direct labor is often an organization cost. Thus most of the labor about a blast furnace should be charged to organization and not to production, because the nucleus of the labor staff must be maintained to keep the furnace in operation at all, whether the production of the furnace be high or low, and in the case of such a furnace the labor nucleus is a large proportion of the total labor. The factor limiting the production of a blast furnace is the life of the lining. Again, the day-rate spinner in a textile mill should be charged to organization, because the number of spinners is fixed by the number of frames in operation, not by the speed, and hence the production of those frames. Doffing, however, is a production cost.

Similarly in each specific case the character of each item of cost can be determined.

The cost curve once established should, in a given plant, be relatively stable. It will, of course, be influenced by changes in prices of raw materials and in wages, but the influence of these changes can be readily estimated. The selling price will, in general, be much more subject to fluctuation. At regular periods, the length of which will vary from industry to industry, depending upon the rapidity of fluctuation of the selling price, the charts indicated above should be constructed and placed before the management as a guide in directing policy with regard to production.

Arghan—A New Fiber

THE cheapness of cotton during the past half century has militated against the introduction of a substitute, but it is interesting to note that the pioneer of the plantation rubber industry, Sir Henry Wickham, realized the possibilities of a plant, now known as arghan, about 50 years ago; but economic conditions during the intervening period did not warrant its cultivation and exploitation. More recently, however, because of the high price of cotton and flax, the inroads of the boll weevil and other factors of economic and international importance, attention was paid in Great Britain to the possibility of the transporting of arghan plants and their cultivation on a large scale. Russia, before her economic collapse, was an important producer of flax. This source is now almost entirely barren, with the result that a shortage of over 500,000 tons per annum must be met by the substitution of other material. A company to develop the arghan industry was organized in London late in 1919, with Sir Henry Wickham as technical adviser.

Transplanting the Plants

As with the beginning of the rubber industry, investigations were made and steps were taken to transplant a large number of arghan plants from their native habitat in the wilds—the precise locality is a secret—and to establish them in a desirable area in the British dominions. From this fact it would appear that arghan, like rubber, is indigenous to a country in which exploitation would be economically impracticable, because of governmental or national instability, of the probability of hampering interference with exportation, or restrictive if not confiscatory legislation. The collection of the plants and their transport to the Federated Malay States proved a delicate task, as was the case with the rubber seeds that were surreptitiously removed from Brazil. More than 500,000 plants were collected, the time involved being over 12 months; of these, less than 4,000 arrived alive at their destination. However, careful attention only was needed to preserve the stock, and recent reports indicate that the success of the enterprise, from the technical standpoint at least, has been complete. A nursery was established far from the native habitat of the plants. Various governments within the British Empire showed a keen desire to co-operate. The government of the Federated Malay States first granted the company a concession of 30,000 acres free of all premium, with a nominal land rent of 50 cents per acre, rising to a maximum of $1·per acre. The value of this concession is indicated by the fact that the rubber companies thereabout pay $4 per acre per annum for the same privileges. This indicates that the colonial government must have been satisfied as to the merits and possibilities of the new fiber. More recently, other colonial governments have evinced a desire to facilitate the expansion of the new industry, and negotiations are under way with India and Ceylon.

Character of the Fiber

Arghan is a perennial, and therefore is easier to produce than cotton or flax (being less liable to the effect of seasonal variations), both of which are annuals. Maturity is reached within 2½ years after planting. The fiber is of unusual strength and resistive power, particularly in regard to salt water. Tests have shown that when fabricated it can bear a strain of 50 per cent above the same class of goods manufactured from Italian hemp or Russian flax. A tensile strength three times that of silk and, weight for weight, the same as steel has been claimed. The fiber content of the leaf amounts to about 20 per cent of its weight, as compared with 3 to 4 per cent in sisal hemp. The analysts to the Federated Malay States Government state that it contains 75 per cent of cellulose, which is above the average for fiber of this class; that it resists alkaline hydrolysis, and that it is remarkably free from lignone. Immersion in salt water for several months showed that the fiber possesses a high degree of chemical resistance. One pound of arghan has been spun into 7,500 yards of material, and even improved results are expected when its properties are better understood. It has been shown to have satisfactory adsorptive qualities, and to take dye satisfactorily. It also bleaches well. The new fiber, which is obtained from the leaf, differs from ramie in that no decortication and degumming difficulties are met with. The method of treatment for the recovery of the fiber is simple, cheap and effective.

A committee of Lancashire manufacturers and spinners has reported that the new fiber will be suitable for twine, cordage, fishing-net yarns, tapes and beltings; and that it will eventually displace cotton from all classes of heavy canvas, particularly where strength is of paramount importance. As to the cost of producing arghan under methods involving scientific plantation control, Sir Henry Wickham states that the plant that yields the fiber is now being placed under cultivation for the first time, and that all estimates are tentative. But, as it belongs to a botanical order characterized by unusual hardiness and rapid growth, it is more than probable that an industry may be established and maintained over large areas of suitable land in the Eastern tropics, at a lower cost than is possible with any other staple product. A preliminary estimate shows that arghan can be produced and marketed for less than 12 cents per pound to yield a satisfactory profit.

Development of the Industry

The parent corporation has instituted a plan for the development of the new industry, whereby subsidiary companies are formed and financed to develop plantations of 5,000 acres each. More recently arrangements have been made with the rubber companies in the Federated Malay States, whereby they are permitted to produce and sell arghan on a royalty basis. This fact is of significance to those interested in the supply of crude rubber. It indicates that the restricted output of plantation rubber may not end in financial disaster to the growers, as has been predicted by manufacturers who would welcome a radical reduction in price.

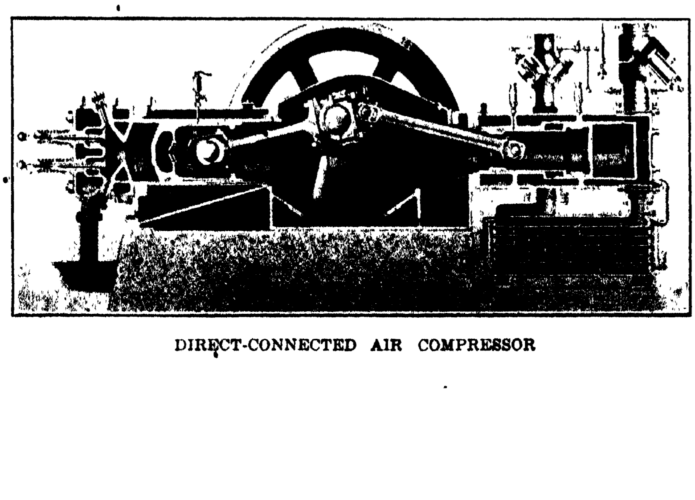
Direct-Connected Air Compressor Unit

The accompanying photograph shows an extremely interesting development of the Price horizontal oil engine which has recently been made by the Ingersoll-Rand Co., of 11 Broadway, New York. In this photograph is shown an oil engine with its cylinder directly in line with the air cylinder of a compressor set on the opposite side of the crankshaft. In the development of 100 lb. air pressure, a two-stage air cylinder is used, with the intercooler situated below the cylinder and forming a support for it. For lower air pressures than this a single-stage cylinder is used, which is connected directly to the oil engine frame. In both the single and two-stage cylinders the air cylinder is double acting, which serves to help the balance of the oil engine. The photograph here shown is of the type used with the 100-hp. unit. In the 50-hp. unit the air cylinder is vertical and mounted on top of the engine directly above the crankshaft.

This same combination of units has also been made in the case of ammonia compressors. In this case, with the 100-hp. unit, there is an actual delivered capacity of gas equivalent to 63 tons of refrigeration, and with the 50-hp. unit, to 31 tons of refrigeration.

It is claimed by the manufacturers of these combined units that great economies are effected by the use of an oil engine in connection with a compressor. In making a comparison with electrically driven units, it is claimed that with fuel oil at 6 cents per gallon the oil-burning engine works on a par with electric power at 1¼ cents per kw.-hr., and with fuel at 12 cents per gallon with electric power at 1½ cents per kw.-hr.

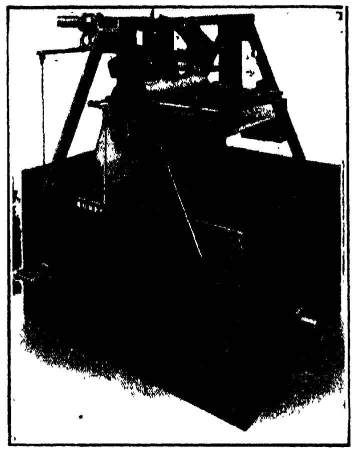


DIRECT-CONNECTED AIR COMPRESSOR

A Weighing Meter For Liquids

The weighing meter shown herewith actually weighs the liquid by balancing a bucket against a balance weight on a scale beam. The bucket rests upon the beam by frictionless trunnions, while the beam is supported on knife-edge bearings. When a certain weight of water has accumulated in the bucket, the latter sinks until it escapes a latch and then quickly turns over and discharges its contents.

During the time that the bucket is rotating, the inflowing water is received in a detaining chamber. As soon as the bucket has discharged, it swings back so that the liquid in the detaining chamber flows into the main bucket, which thereupon proceeds to revolve slowly to its initial position. In so doing it travels a short distance past the latch and then, as more water flows in, slowly comes back against the latch, engaging and locking with the latter, the balance weight having already returned the bucket to its original elevation. There is no shock, jar nor impact at any time during the operation.



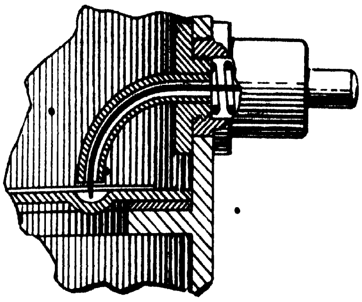
WEIGHING MOTOR WITH OPEN TANK

The bucket trunnions roll upon plane surfaces and there is practically no wear. Each dumping is registered by a counting train. The accuracy is within 1 per cent, plus or minus, at all rates of flow up to the maximum. The meter is easily calibrated by weighing a single discharge and can be adjusted by moving one or both of the counterweights.

This weighing meter can be built in small capacities for which a V-notch would be unsuitable. The receiving tank into which the meter discharges can be fitted with a float controlling a valve in the inlet connections, where the amount is controlled by the apparatus to which the liquid flows rather than by the apparatus from which it comes. This meter is being marketed by the H. S. B. W.-Cochrane Corporation of Philadelphia, Pa.

Time Punch For Recorders

As an additional feature in connection with the "Columbia" line of temperature recorders made by the Schaeffer & Budenberg Manufacturing Co., of Brooklyn, N. Y., a time punch has been added. This feature consists of a punch located



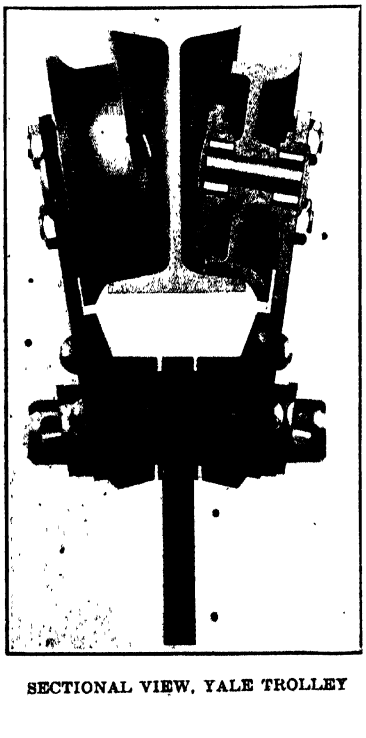
TIME PUNCH

in the rim of the recorder, as shown by the accompanying drawing. When the button is pushed the curved wire makes a perforation in the recorder chart—indicating the time of the punching operation. This feature obviously has numerous uses, such as recording the time at which certain operations are performed or readings taken, or it may be made to serve as a watchman's clock or for similar purposes.

An I-Beam Trolley

The Yale & Towne Manufacturing Co., of Stamford, Conn., has recently designed and placed on the market a new I-beam trolley of the roller-bearing steelplate type. This trolley represents the latest features of this company's trolley design and embodies the following features:

Strength—A reserve of seven times the rated capacity.



SECTIONAL VIEW, YALE TROLLEY

Flexibility—A 1-ton trolley will run on a 21-in. radius curve.

Roller Bearings—These are heat-treated, hardened and ground to give easy lateral motion. They have a grease chamber designed to prevent the dust from reaching them.

Axles—These are set parallel to the I-beam flange, pressed into the wheel hubs and supported by the inner bearing plate. In this way they are subjected to practically no bending strain.

Wheels—These are chilled iron threads conforming to the shape of the I-beam flange, designed to reduce the wear from dust and grit.

Equalizing Pin—This is of cold-rolled steel and will support a shackle, an eye, or a clevis. Where extra headroom is desired, the chainblock can be hooked directly over this pin.

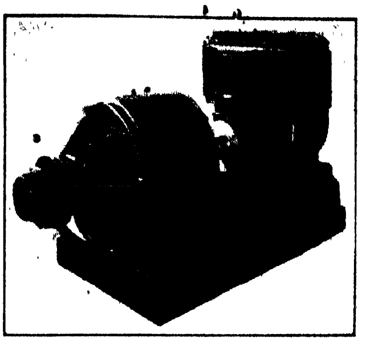
In demonstration of the strength of this trolley, the manufacturer offers the following test: The trolley was loaded with a 28,000-lb. load and the I-beam on which it was supported broke without any damage occurring to the trolley.

Temperature Regulator

The Fulton Co. of Knoxville, Tenn., has recently placed on the market a new temperature regulator which it calls No. 932. This regulator is the latest member of "Sylphon" line of temperature regulators, and is used for regulating the temperature of liquids.

It consists primarily of a thermostatic element, a power transmission unit and a regulating valve. It is in three parts and so arranged that the thermostatic element can be installed in the tank containing the liquid whose temperature is to be regulated, independently of the installation of the outer parts. The valve in the steam line can also be independently installed. After the installation of these two parts, the power transmission unit can be connected between the two, by means of a quick-detachable T-slot connection.

Power between the tnermostat and the regulating valve is transmitted by liquid pressure acting betwen two small "Sylphon" bellows. The liquid contained in this system is a non-freezing liquid which is recommended by the manufacturers as giving frictionless and satisfactory operation. The bellows are of the "Sylphon" corrugated metal type.



THE NEEDHAM BLOWER

Needham Blower

Many offices, such as telephone and telegraph companies, brokers' offices and newspaper offices, use pneumatic conveyor systems for handling papers and other materials between various rooms. For this use, the Needham blower has long had much popularity. In fact these blowers are in use in all the best known telegraph, cable and telephone companies.

The satisfactory operation and many good qualities of this machine, whether used as blower or exhauster, have recently impelled the manufacturers to recommend it for other uses. It is offered for the attention of chemical and allied industry as a solution of some of the problems which are here met with in obtaining satisfactory blowing equipment.

This machine is built in capacities from 75 ft. to 1,500 ft. per minute. It is direct connected through a flexible coupling to a motor mounted on the same base. It has ball bearings throughout, which makes for efficient operation and permits of easy replacements.

The drive is from the motor to a worm which is direct connected to the motor shaft. This worm drives two worm-wheels, one on each shaft of the blower. By this means, power is transmitted evenly to each shaft and any spring in shafts or impellers is eliminated. The impellers are cast integral with the shafts. Shafts are vertical. The general design is along similar designs to that of other well-known positive blowers.

The manufacturers claim that in this machine they have a blower of great reliability which is noiseless; and that it is particularly adapted to automatic control. It is also claimed that it develops double the capacity, for a given size, of any other type of blower.

Review of Recent Patents

Some Hints for the Technical Man

Patents Dealing With Cane Juice Purification, Wool Cleaning and Paper Recovery Deserve Attention

THE TREND of industry as revealed by patent literature in the last decade shows a marked increase in the number of new alloys patented. This is significant. It is an indication of the increasing attention that is being focused on the scientific production of alloys and metallic products. Less and less the old cook-book methods, more and more an intelligent application of clear-headed, planned experimentation.

This observation was stimulated by a patent on the manufacture of silicon-manganese-iron alloys, (1,449,373, issued to W. J. Beck and J. A. Aupperle, assigned to the American Rolling Mill Co. of Middletown, Ohio; March 27, 1923.) By the addition of 2 to 4½ per cent silicon to iron to which has also been added manganese, a corrosion-resistant alloy is produced. The addition of manganese to an alloy increases its workability. The theory is that the iron alloyed with silicon when exposed to natural oxidation takes on a thin, velvety, protective coating, made up largely of black magnetic oxide of iron, together with silicate of iron. The silicon in the alloy prevents the formation of higher oxides upon the surface of the metal. This coating acts as an enamel covering on the surface of the metal, preventing formation of ordinary rust-ferric oxide, Fe_2O_3.

Purifying Raw Cane Juice

The cost and time required in the purification of raw cane juice are excessive and all effort expended on the diminution of these invaluable commodities is in lin with economic progress and health. This is by way of explanation of our interest in such patents as this one (referred to below) and to enunciate from time to time a useful criterion of attention value. The clarification of raw cane juice is complicated by several factors. If it is filtered and then neutralized with milk of lime and filtered again, the filtration is slow, unless a filter aid is used. On the other hand, if the preliminary filtration is omitted, the fine fibers from cane give up albuminous matter which is coagulated on neutralization and heating. This makes filtration extremely difficult. C. J. G. Sorenson, of Frederiksted, Virgin Islands, has patented a method for handling this problem. (1,448,421; March 13, 1923.) The raw juice is neutralized with milk of lime and heated under 40 lb. pressure to a temperature of 110 deg. C. The juice still contains the small fibrous particles, bagacilio, of cane. By pumping directly to a filter press out of contact with air, the albuminous matter is kept from coagulating.

Advance in Paper Technology

The increasing cost of new stock for paper manufacture is creating a condition that makes improved recovery

American Patents Issued May 22, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met* readers. They will be studied later by *Chem & Met's* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,455,785—Screening and Sizing Process and Apparatus. G. C. Hackstaff, Denver, Colo.

1,455,789—Apparatus for Automatically Extinguishing Fires in Oil Tanks and Other Structures. O. J. Holmes, Tulsa, Okla.

1,455,791—Flux or Solvent for Use in Technical Process. A. A. Kelly, London, England, assignor to Borax Consolidated, Ltd., London.

1,455,809—Elastic Gasket Composition. J. Ritter, Pittsburgh, Pa., assignor to Whitaker-Glessner Company, Wheeling, W. Va.

1,455,834—Method of and Apparatus for Cleaning Gases. A. N. Diehl, Duquesne, Pa.

1,455,846—Air-Conditioning or Humidifying and Heating System. L. L. Lewis, Plainfield, N. J., assignor to Carrier Engineering Corporation, New York.

1,455,893—Unvulcanized Rubber Composition. F. W. Stockton, Pittsburgh, Pa., assignor to Aluminum Seal Co., New Kensington, Pa.

1,455,907—Vibrating Trommel Screen. A. C. Daman, Denver, Colo.

1,455,911—Oil Purifier. A. R. Giffin, Cleveland, Ohio, assignor to J. E. Heene, Cleveland.

1,455,927—Method of and Apparatus for Preventing the Absorption of Air by Boiler-Feed Water or Other Liquid. D. B. Morison, Hartlepool, England.

1,455,963—Lithopone and Method of Manufacture. V. F. Meister, Collinsville, Ill.

1,455,966—Mechanism for Conveying Hot Glassware. M. J. Owens, Toledo, Ohio, assignor to Owens Bottle Co., Toledo.

1,455,975—Apparatus for Puffing or Disintegrating Material. A. R. Spencer and W. J. Plews, Cleveland, Ohio.

1,455,995—Bleaching Earth. C. Cramer, Zurzach, Switzerland.

1,456,016—Liquid Heater and Vaporizer. C. E. Ward, Charleston, W. Va.

1,456,019—Process for Extracting Oil. H. A. Wentworth, Deer Island, N. B., Canada.

1,456,023—Furnace Arch Construction. L. H. Hosbein, Chicago, Ill., assignor to M. H. Detrick Co., Chicago, Ill.

1,456,035—Metal Dust and Process of Making the Same. M. H. Newell, San Francisco, Calif., assignor to the Alloys Co., San Francisco.

1,456,044—Positioned Electrode. W. W. Strong, Mechanicsburg, Pa., assignor to Research Corporation, New York.

1,456,057—Fuel Economizer. W. G. Griffin, Washington, D. C.

1,456,064—Process and Apparatus for Making Sulphuric Acid. W. F. Lamoreaux, Isabella, Tenn.

1,456,065—Manufacture of Sulphuric Acid. W. F. Lamoreaux, Isabella, Tenn.

1,456,067—Apparatus for Screening Granular Materials. R. A. Leahy, Bonne Terre, Mo.

1,456,095—Pressure Oil Filter. F. E. Collins, Conshohocken, Pa.

1,456,102—Chemical Apparatus. B. B. Fogler, Cleveland, Ohio, assignor to General Electric Co.

1,456,111—Clay Products and Process of Preparing Same. E. G. Acheson, New York.

1,456,112—Reflocculated Product and Process of Preparing Same. E. G. Acheson, New York.

1,456,147—Agitating Device. T. J. Putnam, Boston, Mass.

1,456,165—Ore Separator. S. H. Whitney, San Francisco, Calif., assignor of one-fourth to A. A. Eddie, San Francisco.

1,456,224—Method and Machine for Making Prepared Roofing. A. E. Currier, Millis, Mass., assignor to Baker Rubber Cement Co., Boston.

1,456,252—Process of Coating Metals with Metal Phosphides. S. Peacock, Wheeling, W. Va., assignor to Wheeling Steel & Iron Co., Wheeling.

1,456,255—Apparatus for Heat Exchange. E. Shaw, Toronto, Ont., Canada.

1,456,270—Sugar-Washing and Water-Measuring Device. W. W. Hartman, Los Angeles, Calif.

1,456,274—Process of Rendering Metal Non-Oxidizable and the Metal. W. J. Keep, Detroit, Mich.

1,456,303—Acid-Proof Mortar. P. G. Ekstrom, Stockholm, Sweden, assignor to Aktiebolaget Syrefast Murning, Stockholm, Sweden.

1,456,312—Combined Sludge Separating and Drying Basin. K. Imhoff, Essen, Germany.

1,456,323—Process for Treating Woods and Other Porous Substances. E. H. McPherson, Los Angeles, and J. M. Abrams, San Francisco, Calif.

1,456,332—Process of Drying and Preparing Fertilizing Materials. F. J. Nash, Brooklyn, N. Y.

1,456,341—Explosive Composition. W. O. Snelling, Allentown, Pa., assignor to Trojan Powder Co., New York.

1,456,353—Mill. D. D. Bare, West Jefferson, N. C.

1,456,360—Air Filter. A. Budil, Berlin-Tempelhof, Germany.

1,456,360—Thermoplastic Composition and Process of Compounding the Same. E. de Stubner, New York, assignor to Columbia Graphophone Manufacturing Co., Bridgeport, Conn.

1,456,370—Process of Making Waterproof Rigid Articles from Pulp. W. H. Drake and J. J. Drake, Cleveland, Ohio.

1,456,390—Safety Device for Plants Delivering Inflammable Liquids. M. Ludwig, Berlin-Lichterfelde, Germany, assignor to Martine & Hüneke Machinenbau-Aktien-Gesellschaft, Berlin.

1,456,392—Retort for the Treatment of Carbonaceous or Other Materials. F. D. Marshall, Westminster, London, England.

1,456,419—Process and Apparatus for the Production of Low Boiling Point Hydrocarbons. J. C. Black, Destrehan, La.

1,456,438—Liquid Filter. K. J. E. Hesselman, Saltsjo-Storangen, Sweden.

1,456,486—Compound for Cleaning Aluminum. C. M. Hemen, Washington, D. C.

1,456,492—Surfacing Composition for Highways and the Like. D. M. Hepburn, Philadelphia, Pa.

1,456,494—Oilproof Coating or Impregnating Agent. A. J. Rowland, Cincinnati, Ohio.

1,456,495—Manufacture of Carbon Electrodes. S. E. Sieurin, Hoganas, Sweden, assignor to Höganäs Billesholms Aktiebolag, Helsinborg, Sweden.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

methods for old stock highly desirable. B. M. Baxter, of Cleveland, Ohio, seeks to make possible the recovery of fiber in waste paper contaminated by various foreign materials. (1,451,522, assigned to Air Reduction Co. of Pittsburgh, April 10, 1923.) In principle the apparatus consists of a long rotating slotted drum suspended partly submerged in a tank of water. The drum is provided with openings in both ends. Into one end the paper waste is fed. The waste in rubbing over these slots as the drum revolves is reduced to pulp and flows out into the tank. Angle irons are so located as to elevate waste solids to the discharge opening. The process is thus continuous and is claimed to give cheaper and more satisfactory recovery of fiber from refuse than any method now in use.

Zinc Oxide Process

The New Jersey Zinc Co., through J. A. Singmaster and F. G. Breyer, has patented an operating improvement in the Wetherall process. (1,450,704; April 3, 1923.) This process is a preliminary step in the production of zinc oxide and consists in making the zinciferous material ready for the production of zinc oxide. It consists essentially in adding to the charge itself an admixture of porous non-slagging material. This diminishes the tendency to slag and block up the charge—a process that effectively prevents further roasting. Furthermore, the process suggests the use of a layer or bed of this non-slagging porous material between the working charge and the ignition fuel. It is claimed that greater facility of operating is obtained, greater flexibility of operating conditions and correspondingly better yield of well-roasted ore.

"Dry Cleaning" Wool

The removal of dirt and grease from wool without the assistance of a liquid solvent is claimed by H. Y. McBride. (1,449,613; March 27, 1923, assigned to the United States Wool Co.) Gypsum is the degreasing agent, but it must be prepared by burning to a point where it will no longer take up any moisture. In other words, it is completely dead-burned. In addition it is necessary to grind the gypsum to a very fine powder—about 250 mesh. The wool is rotated with the gypsum in a tumble barrel and then removed and shaken free by a dusting process which is standard trade practice. It is claimed that the wool may then be spun and dyed with unusual facility.

Sizing Composition for Paper

A sizing composition especially suitable for the tub treatment of high-grade paper results from the treatment of alum-tanned leather scrap with water at higher temperatures. Pieces of scrap in a tub or vat are washed with water to remove as far as possible the salt and alum. The salt is washed out thoroughly and the solution, consisting of scrap mixed with ten times its weight of water, is heated by steam until the leather has been entirely dissolved. A clear light-colored sizing composition results. This may be applied directly, but the addition of enough alum to give 10 per cent concentration on the basis of the dry leather scrap originally used is recommended. After this addition the mixture should be heated sufficiently to incorporate the alum thoroughly. (1,449,892, issued to P. W. Codwise; March 27, 1923.)

Fireproofing Compound

A cheap method of producing fireproof construction is suggested by W. L. Wooton of Brooklyn. (1,451,485; April 10, 1923.) Essentially it means the impregnation of wood and fiber with calcium chloride with which is mixed small quantity of salt and gypsum. It is prepared by adding to 150 parts of slaked lime and one part of salt a mixture containing 99 per cent by volume of hydrochloric acid and 1 per cent sulphuric acid. This mixture can be used directly for impregnating cotton and other textile fabrics, plaster, wood and so forth. The composition, being infusible, renders the impregnated material fireproof. No details are given as to method of impregnation.

Book Reviews

Nitrogen—In Peace or War

Review of Some Current Literature of International Significance

By Grinnell Jones

THE NITROGEN INDUSTRY By *J R Partington* and *L. H. Parker* xi + 336 pp. 23 figures and 19 plates. Constable & Co, London, 1922 (D Van Nostrand, New York, 1923) Price, $6

THE rapid growth of the nitrogen industry and the great stimulus to research on nitrogen fixation during and since the war have inspired the publication of several new books. A German, B. Waeser, has produced a typical Teutonic handbook, "Die Luftstickstoffindustrie," systematic, detailed, ponderous, but relatively free from critical analysis and comparison of the various processes; essential to the reference library and to the specialist on nitrogen fixation, but a bore to most readers.

Les Mémoires de la Société des Ingénieurs Civils de France (eighth series, vol. 75, pp. 172-342, 1922) contains a series of articles broadly covering the nitrogen industry, chiefly notable for the best available description of the Claude process, written by Claude himself.[1]

The splendid group of American chemists at work in the Fixed Nitrogen Research Laboratory at Washington have published a "Report on the Fixation and Utilization of Nitrogen" (No. 2041, 1922), which contains a detailed description and a critical comparison of the existing processes. This report also contains considerable disclosures of the conclusions reached as a result of the research that has been carried out in this laboratory, but it is not burdened with the details of the experimental proof of the conclusions.

From England we have the "Final Report of the Nitrogen Products Committee to the Ministry of Munitions of War" (1919), together with a later "Statistical Supplement" (1921), which, although weak on the purely technical side, is unique for its systematic compilation of the world statistics of the industry and for its discussion of the competitive strength of the different branches of the nitrogen industry.

[1]For an abstracted translation see *Chem. & Met.*, vol. 28, No. 11, pp. 498-501. March 14, 1923.

"The Nitrogen Industry"

From England we have also the volume by Partington and Parker, the primary subject of this review. This book is so profoundly influenced by the earlier British report just referred to that it may almost be regarded as a popularized edition of it, with many good pictures and much more or less superficial technical descriptions added. The authors emphasize the vital importance of nitrogen fixation to Great Britain in war and peace and freely criticize the handling of the situation by British officials and financiers.

The book discusses the Chilean nitrate industry, byproduct ammonia, synthetic ammonia, the cyanamide process, the arc process and the oxidation of ammonia. The chapters dealing with the Chilean nitrate industry and the oxidation of ammonia are the best. Many statistical tables are taken from the earlier British report with little if any effort to bring them down to date. The thermodynamic and kinetic theory of the processes is touched on very lightly. Indeed, the presentation is so simple, clear and superficial that it can be followed by a reader having only the most elementary knowledge of chemistry. Disclosures of information which has not already appeared in the technical press are conspicuously absent. Thus the description of the catalysts for the ammonia synthesis is confined to the following:

> The catalysts are usually mixtures of various substances. Metallic iron is the main constituent, but small amounts of other substances called "promoters" are added. One of these is molybdenum. Uranium may also be used. Very pure

iron, according to Nernst, has a very slight action only. . . . . The catalyst was stated to be the same as that used in ammonia oxidation, probably oxide of iron and chromium; it remains active for 2 years

In view of the fact that the German plants have been visited by British, French and American chemists and that the authors have been members of a British organization which has been active in research work on nitrogen fixation the inference is plain that the authors, if they had desired to do so, could have given a much more detailed and accurate account of the chemical nature of the catalysts; of the method of their preparation; their efficiency under various conditions of temperature, pressure and gas velocity; and their sensitiveness to poisons.

This book will be the least valuable to the specialists of any of the new books on nitrogen fixation referred to above. But the book can be fairly judged only with reference to the purpose of the authors—viz., to impress upon the general public the unique position of "the greatest, the most important key industry of all." Judged in the light of this purpose, this book is admirable. It is to be hoped that in America, as well as in Great Britain, it will reach a large public chemists, newspaper editors, Congressmen, investors, public spirited citizens. Let every chemist buy a copy to lend to his friends and see that a copy is made available in the public library in his home town!

CONTRASTING OUR POSITION WITH ENGLAND'S

The American reviewer feels constrained to reply to this criticism of Great Britain by a Briton. If the submarine had actually secured command of the sea, as it so seriously threatened to do in 1917, Great Britain would have been forced to acknowledge defeat through starvation with or without a nitrogen fixation industry at home. It was therefore sound public policy for Great Britain, in the crisis of the war, to concentrate her full resources in steel, labor, and in the brains of her scientific men and inventors to the conquest of the submarine, to the neglect of all other things Even a well-developed nitrogen industry yielding a large surplus for fertilizer above the military requirements could not make Great Britain independent of imports of food. The submarine was mastered in the nick of time and the policy of the government was thus justified by success.

In the United States, on the other hand, the situation was and remains fundamentally different. In 1917 the possibility had to be faced that the submarine would secure virtual command of the sea. In such a contingency the United States, although denied a definite victory, could at least avoid defeat through invasion as long as the supply of explosives did not cease through lack of nitrates. With an adequate supply of nitrates available from the air, the United States and Canada together could defend themselves against invasion indefinitely even if completely shut off from imports by sea. A failure in the supply of rubber would be embarrassing and of coffee inconvenient, but no imported article, except sodium nitrate, is really essential for the national existence and military defense. This is the reason that the United States in 1917 and 1918 made frantic efforts to secure a supply of nitrates from a source beyond the reach of the submarine, whereas Great Britain postponed the problem until after the war. The lesson of this English book on "The Nitrogen Industry" is thus even more vital to the United States than it is to Great Britain.

Index for Engineers

CATALYSIS IN ORGANIC CHEMISTRY. By York, 1923, The American Society of Mechanical Engineers. 675 pp. Price, $6

This work, the best yearly index of periodical literature from the engineer's point of view, reaches with this issue its twenty-first volume. Throughout its long record of service the book has year by year become more valuable; its field of action has been made broader by the inclusion of more and more publications among those received, and the presentation, especially with reference to the method of classifying and cross-indexing, has been improved.

The number of publications reviewed now covers fully 1,300, including periodicals, reports and other items. Of these, articles to be indexed have been selected from over 600, of which approximately 50 per cent are foreign publications. The individual references have been written in a much more concise form than formerly, thus permitting an index of greatly increased scope to be published with the addition of but few pages.

G. L. MONTGOMERY.

Important Articles in Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem & Met* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature and consequently should be of considerable interest to our readers Those that are of unusual interest will be published later in abstract in this department, but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage The magazines reviewed have all been received within a fortnight of our publication date

FORMATION, CHEMICAL CONSTITUTION AND UTILIZATION OF OIL. Eugene Grandmongin The first of a series of reviews on industrial science written for the engineer *Le Génie Civil*, May 12, 1923, pp 144-6

AUTOMATIC REGULATION OF NITROGEN OXIDES IN THE CHAMBER PROCESS OF SULPHURIC-ACID MANUFACTURE. Kai Warming Outline of a proposed system based on temperature differences between chambers. *Chimie et Industrie*, April, 1923, pp. 671-3.

SYNTHETIC TANNINS R. B. Croad. Review of the history, methods of manufacture and use of these products. *J Soc Chem. Ind.*, May 11, 1923, pp 203T 207T.

THE LLANDARCY REFINERY OF THE ANGLO-PERSIAN CO. A semi-technical discussion of the first Anglo-Persian plant to be installed in South Wales. *Chemistry & Industry*, May 18, 1923, pp 482-6.

THE STREAM-LINE FILTER. J. W Hinchley. A note on a new filter invented by Prof. Hele Shaw. *Chemistry & Industry*, May 18, 1923, p. 489.

METHODS OF ESTABLISHING WAGE RATES AND DETERMINING PROMOTIONS H P Carruth. A reduction of personnel problems to a fixed basis by use of questionnaires and graphic ratings. *Paper Trade Journal*, May 24, 1923, pp 49-58.

CONTINUOUS DIGESTION OF PAPER PULP. Raymond Fournier. A proposed apparatus which makes continuous digestion possible under moderate pressure. *Paper*, May 23, 1923, pp. 5-6.

LEACHING OF TANNIN MATERIALS. J. A. Reavell Notes on the Thorncroft Patent Leaching Apparatus. *Chemical Age* (London), May 12, 1923, pp. 506-8

MOST MODERN CEMENT PLANT IN FRANCE J. Prouteau. Poliet & Chausson Plant at Gargenville has most up to date apparatus on all departments. *Rock Products*, May 19, 1923, pp. 11-20.

COAL CARBONIZATION AS APPLIED TO POWER-PLANT PRACTICE. V. Z. Caracristi. The lead bath method of low-temperature carbonization applied in the boiler house. *Power*, May 29, 1923, pp. 831-6.

Fundamentals of Catalysis

CATALYSIS IN ORGANIC CHEMISTRY. By *Paul Sabatier*, translated by *E. Emmet Reid* 406 pages. D Van Nostrand Co., New York, 1922. Price, $5.

There is only one reason now why Sabatier's text on catalysis in organic chemistry should be read in the original French. If you are unskilled in the reading of scientific French, Sabatier's book is a good text to study, with its relatively simple language forms, its wide range of scientific words and the general interest of the subject to hold your attention. But Professor Reid's translation is a far more useful text if it is information on the subject of catalysis that you need. It is broader, it is better, more accurate and more detailed than the original, which itself is a classic. So it is not even necessary to say that the book is indispensable. Anyone who takes catalytic work seriously, and most of us ought, would be foolish to be without it.

The book is a detailed record of the contributions of the catalytic investigators to preparative organic chemistry. It is especially concerned with the reactions of hydrogenation and dehydrogenation, hydration and dehydration, those reactions in which the Sabatier researches have been most fruitful, in which the contact catalyst has meant the ready attainment of otherwise difficult ends and in which new processes of the laboratory and the industry have found their origin. As a compendium of such it is invaluable. It has a further value to those who would know what has already been accomplished and who would embark upon the labors of extension and amplification; because, on reading this book, one cannot but be struck with the largely empirical nature of the achievements in contact catalysis. And to some of us there must come a desire to see the empirical make way for the more rational. To do this, however, we must know, thoroughly, the empirical.

It is on the theoretical side that Sabatier's book is weakest. Professor Reid has helped materially to correct this by incorporating a chapter by Professor Bancroft on theories of catalysis. Reading this section, how-

ever, the reviewer feels that a considerable period of time must have elapsed between the receipt of the contribution and the publication of the book. Professor Bancroft's views have already progressed materially beyond the thoughts expressed in the chapter he contributes to this book. In addition to this chapter there are copious signed footnotes by various interested workers in the field in this country which amplify very helpfully the data in the text.

The method of paging is confusing, the numbers being on the inside edge of the page, paragraph numbers occupying the position usually occupied by page numbers. One doubts whether this is wise.

From the graceful biography of Sabatier contributed by the translator the pessimistic research man may take courage. The work which has rendered Sabatier's name illustrious in the annals of his science was all done after 20 years of research work in another branch for which he is practically unknown.

HUGH S. TAYLOR.

Men in the Profession

E. E. AYARS, chairman of the refractories division of the American Ceramic Society and recently superintendent of the silica brick plant of the American Refractories Co., at Joliet, Ill., has severed his connection as a result of the change in management of this plant. Mr. Ayars had been in the employ of the American Refractories Co. in various capacities in the operating department for 5½ years.

MARION G. BRYCE, president of the United States Glass Co., Pittsburgh, Pa., was tendered a testimonial dinner by stockholders in the company at the William Penn Hotel, May 22. Ernest Nickel, treasurer of the company, acted as toastmaster.

H. V. BURGARD, consulting metallurgist, of Hollywood, Calif., has returned from an extended trip in Arizona and Nevada on professional business.

J. V. N. DORR has been made an honorary member of the Phi Lamda Upsilon scholastic chemical fraternity.

R. C. HARTONG, formerly chief chemist at the plant of the Goodyear Tire & Rubber Co., of Akron, Ohio, has been elected president and treasurer of the Chemitex Products Co., recently organized to establish a plant at Mogadore, near Akron.

Dr. VICTOR F. HESS, chief physicist of the U. S. Radium Corporation, has resigned to assume the chair of experimental physics at the University of Graz, in Austria.

Dr. GUSTAVE E. LANDT has resigned his position on the teaching staff of Columbia University to engage in research and development work with the Agosote Millboard Co., Trenton, N. J.

D. S. MCAFEE, of the Dorr Co., was recently in San Francisco.

JOSEPH MCAULIFFE has resigned as mill superintendent of the Caribou Metals Co. to devote his entire time to the Mace Co. G. G. GENTRY has succeeded Mr. McAuliffe as mill superintendent of the Caribou Metals Co.

E. B. MILLER, vice-president of the Davison Chemical Co., Baltimore, Md., addressed a meeting, held under the auspices of the local sections of the American Society of Mechanical Engineers and the American Chemical Society, at Baltimore, on May 25. His address was on "The Refining and Recovery of Petroleum Oils by Silica Gel."

GEORGE K. MORROW has been elected president of the American Cotton Oil Co., New York, succeeding Lyman N. Hine. Mr. Hine will become vice-president and devote a portion of his time to the affairs of the company.

F. N. RHODES, assistant works manager for the Wilson Portland Cement Co., Ltd., of Auckland, New Zealand, was in San Francisco recently and visited nearby cement plants.

Dr. E. E. SLOSSON is en route to Sweden to be a guest, along with a small group of journalists, of the municipality of Gothenburg at its tricentennial.

Obituary

JOHN VAN VORST BOORAEM, aged 86, for half a century a prominent engineer in the sugar-refining industry, died on May 24 at his home in Brooklyn, N. Y., after a brief illness. As a young man Mr. Booraem studied engineering for 5 years in France and Germany. In 1861 he was engaged as a marine engineer for the government. From 1870 to 1882 he was connected with the Decastro & Donner Sugar Refining Co. and from 1882 until 1898 he was consulting engineer for the American Sugar Refining Co.

WILLIAM D. FRERICHS, a pioneer in the terra cotta industry and one of the organizers of the Atlantic Terra Cotta Co., New York, died at his residence on Amboy Road, Tottenville, Staten Island, May 17, aged 77 years. He entered the employ of the Perth Amboy Terra Cotta Co., Perth Amboy, N. J., about the time that this company was formed, in 1877, then the only company in America devoted to this line of manufacture. Following a reorganization of the Atlantic Terra Cotta Co, several years ago, Mr. Frerichs resigned and became affiliated with the Federal Terra Cotta Co., Woodbridge, N. J.

Dr. HANS GOLDSCHMIDT, inventor of the "thermit" reaction between metallic oxides and powdered aluminum, now widely used as a process for welding steel and for producing some of the less common metals and alloys, and the originator of many other scientific inventions, died suddenly in Baden-Baden, Germany, on May 20, 1923. Professor Goldschmidt was born in Berlin in 1861. His father was the proprietor of chemical works and tin smelters which he had founded in 1847. Hans Goldschmidt studied at the universities of Berlin, Leipzig, Heidelberg, Strassburg and at the Institute of Technology at Charlottenburg, receiving the degree of Ph.D. from the University of Heidelberg in 1886. In 1887 Goldschmidt entered the firm of Th. Goldschmidt, Essen Ruhr, Germany, in joint partnership with his brother. The attention of the latter was applied mainly to the business management of the company, while Hans devoted himself to scientific research. Under their joint guidance the firm grew rapidly in importance. Professor Goldschmidt visited this country very frequently in the years before the war, to supervise his interests in the Goldschmidt Thermit Co. (now the Metal & Thermit Corporation). Through his death the world loses a chemist of great knowledge and inventive genius.

Calendar

AMERICAN ASSOCIATION OF CEREAL CHEMISTS, ninth annual convention, Hotel Sherman, Chicago, June 4 to 9.

AMERICAN CHEMICAL SOCIETY, fall meeting, Milwaukee, Wis., Sept. 10 to 14.

AMERICAN CHEMICAL SOCIETY, New York Section, regular meeting, Rumford Hall, Chemists' Club, June 8.

AMERICAN ELECTROCHEMICAL SOCIETY, forty-fourth meeting, Dayton Ohio, Sept. 27 to 29 (dates provisional)

AMERICAN ELECTROPLATERS SOCIETY, eleventh annual meeting, Providence, R. I., July 2 to 5

AMERICAN GAS ASSOCIATION, annual convention, Atlantic City, Oct. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, summer meeting, Wilmington, Del., June 20 to 23.

AMERICAN LEATHER CHEMISTS ASSOCIATION, twentieth annual convention, Greenbrier, White Sulphur Springs, W. Va., June 7, 8 and 9.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS, iron and steel exposition, Buffalo, N. Y., Sept. 24 to 28.

AMERICAN SOCIETY FOR TESTING MATERIALS, twenty-sixth annual meeting, Chalfonte-Haddon Hall Hotel, Atlantic City, June 25 to 30.

INSTITUTE OF MARGARIN MANUFACTURERS, fourth annual convention, Hotel Traymore, Atlantic City, June 14 and 15.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH), New York, Sept. 17-22.

NATIONAL FERTILIZER ASSOCIATION, thirtieth annual convention, White Sulphur Springs, W. Va., June 11 to 16.

NATIONAL LIME ASSOCIATION, fifth annual convention, Hotel Commodore, New York City, June 13 to 15.

SOCIETY FOR STEEL TREATING, Eastern sectional meeting, Bethlehem, Pa., June 14 and 15.

TAYLOR SOCIETY, Hotel Onondaga, Syracuse, N. Y., June 7 to 9.

Industry and Trade

Current News and Market Developments

Summary of the Week

The Geological Survey reports material increases in production of lead and zinc pigments for 1922.

German producers of chemicals and dyes are reported to be considering establishment of plants in the United States.

Official customs returns show that exports of chemicals and allied products for April were valued at about the same totals as those for March.

Standards of strengths for coal-tar products are expected to be announced very soon. They will form a basis for levying duties on imports.

Advices from Germany state that there is a scarcity of caustic soda in that country.

Imported chemicals are held in large amounts in the spot market and prices are being shaded on many selections.

The lower selling prices for gasoline have brought out an easier situation in motor benzol.

The shortage of arsenic, which was predicted earlier in the season, has not stimulated buying and prices are working lower.

Prices for future positions of linseed oil are considerably under spot prices, reflecting an easier market for seed.

Copper sulphate of foreign make is steadily declining in price with considerable stocks to be worked off.

As a result of the recent conference of the American States, trademarks of this country may be recognized in South American countries.

A committee has investigated conditions in the customs service at New York and made suggestions to expedite the passage of imported goods to the consignees.

The Tariff Commission is reported to have under consideration a plan to compile its own figures on imports and exports, independent of the Commerce Department.

Resale lots of phenol sold at 45c. per lb., which is a drop of 10c. per lb. from the recent high.

The U. S. Treasury is seeking $40,000 as duty charges against the cargo of German dyestuffs brought in on the submarine "Deutschland."

A decrease in the April wholesale trade of 9 per cent from the March record was announced by the Federal Reserve Board.

Electrochemical interests are negotiating for water power rights in North Carolina and Tennessee.

French chemist claims to have devised process whereby coal can be dissolved.

The daily average production of petroleum in April increased to the high record of 1,937,767 bbl.

Some round lots of cyanide of soda changed hands, with imported bringing 20c. per lb.

Germany Striving to Preserve Its Chemical Industry

Intensive Efforts to Maintain Manufacture on Large Scale—Relief From Export Taxes Asked—Lower Freight Rates and Reduced Coal Prices Demanded—Establishment of Plants in United States Considered

GERMANY is more anxious to preserve its chemical industry than any other activity within its boundaries. Latest advices from that country indicate that intensive efforts to that end are being exerted. The Germans would rather maintain their chemical industry than even the manufacture of iron and steel, despite the success which always has attended their operation of metallurgical plants.

The principal reason for the desire to make the chemical industries Germany's greatest industrial endeavor is the fact that it uses German raw materials almost exclusively. It provides more labor for Germans and presents a field in which the Germans believes they are particularly skilled.

To this end the German chemical manufacturers are demanding relief from export taxes. In addition, they are asking special reductions in the matter of freight rates and coal prices. It is contended that all other industries can afford to contribute something to the effort to restore the chemical industry to its former pre-eminence.

It is known that the Aniline Cartel is only awaiting the agreement on reparations to begin a very active campaign. The cartel is more concerned because of the loss of American business than over any other development of the post-war period. The fact that American dye manufacturers now are furnishing 93 per cent of all dyes used in the United States is a severe blow to the cartel. The successful production of blue indanthrene in America has convinced the German chemists that the American industry soon will attain as high efficiency as ever was reached in Germany.

Serious consideration is still being given to the establishment of large plants in the United States. Once that the reparation matter is settled, it is believed that Carl von Weinberg will make the long-promised survey of the American situation. Apparently there is a widely held belief that the interests of the Bädische can be forwarded by the establishment of plants in the United States.

It is known that most of the French dye manufacturers believe their interests would be served best by effecting a close working agreement with the Bädische. There is every reason to believe that the progress already made in that direction will continue.

April Exports of Chemicals Practically of Same Volume as March Shipments

Soda and Fertilizer Groups Show Increase—Outward Movement of Explosives Displays Decided Slump

EXPORTS of chemicals and allied products in April continued in practically the same volume as during March. In the grand total there was a difference of $360,000 in favor of March, but there were several instances of decided increases among the chemicals proper. Both the soda and fertilizer groups showed increases over March. The value of April exports was at a rate nearly $2,000,000 in excess of the rate of the chemical exports in April, 1922.

Sodas and sodium compounds to the extent of 36,605,402 lb. were exported in April. The value of pigments, paints and varnishes exported in April was about $200,000 less than in March, but still is decidedly ahead of the rate of exportation in April of 1922.

Fertilizers and fertilizer materials to the extent of 98,236 tons were exported in April. This compares with 89,519 tons in March and 87,161 tons in April of 1922. The increase applied as well to sulphate of ammonia. The April exports of that commodity amounted to 15,670 tons, as compared with 12,951 tons in March and 12,743 tons in April, 1922. The heavy movement of this commodity to Spain has ceased entirely, but shipments in greater volume are moving to the Orient.

One of the big slumps of the month was in the explosives group. In March 3,254,747 lb. of explosives was exported. This fell to 1,744,405 in April.

Certain of the individual items in which decided changes in movement are taking place are as follows:

	April, 1922	April, 1923
Quinine, oz	9,102	22,038
Sulphuric acid, lb	1,991,368	368,586
Wood and denatured alcohol, gal ..	62,579	81,085
Ammonia and ammonium compounds, lb .	281,817	562,594
Calcium carbide, lb	1,559,138	407,658
Bleaching powder, lb	2,788,056	659,335
Copper sulphate, lb	917,495	47,010
Cyanide of soda, lb	180,070	447,773
Borax, lb	1,625,025	4,217,604
Caustic soda, lb	15,017,777	12,284,777

The figures are those of the Department of Commerce. They have just been compiled from the returns from the forty-eight customs districts in the United States.

Electric Founders Continue Research Activities

The Electric Steel Founders' Research Group held a regular meeting of executives of the five electric steel foundries conducting co-operative research work, at Wernersville, Pa., May 14 to 17. The various phases of the research work being done by the members of the group to improve the quality of steel castings and increase efficiency in methods were discussed in detail. Formal reports giving the status of the present research investigations were read on such subjects as facing sand mixtures, core sand mixtures, electric furnace practice, heat-treatment of steel castings, production control and porosity in castings.

At this meeting plans were made for conducting research investigations on additional steel foundry problems. The results obtained from the work done so far have been so beneficial as to make it highly desirable to study intensively some of the additional complex problems involved in making thin section electric steel castings of intricate design.

Plans for Paper and Pulp Research Announced

During the coming year the Technical Association of the Pulp and Paper Industry proposes to carry on the work of research which has been undertaken during the past few years. The general standing committee covering the manufacturing processes—mechanical, sulphite, sulphate and soda pulp—will continue its investigation of proposed modifications and of the use of newly developed apparatus, at the same time fostering improvements in efficiency and the establishment of standard practice.

Among the subjects of research will be gum and wax papers, the development of special test methods for special products, and research on drying of paper and pulp products. The work of the waste committee on white water losses and on heat losses throughout the mill will be carried on vigorously. As an aid in cellulose research, it is intended to co-operate with the Cellulose Division of the A.C.S.

Sigurd Dyrup on European Trip

Sigurd Dyrup, formerly of Copenhagen, Denmark, now technical director of the Cook Paint & Varnish Co., Kansas City, Mo., has sailed for a couple of months' trip abroad, checking up latest developments in the paint and varnish industry. While abroad, Mr. Dyrup will visit the plants manufacturing some of the most important basic commodities. He will return to this country in time to supervise arrangement and installation of new mechanical and chemical apparatus in Cook's new factory, which will be completed by that time.

A farewell dinner was given Mr. Dyrup previous to his departure, at which Charles R. Cook, president of the Cook Paint & Varnish Co., presented him with a sapphire and diamond scarf pin.

Vigorous Activity in California Cement Industry

Expansion in the hydro-electric power industry in the West is largely responsible for a considerable spurt in the production of cement in California. The Santa Cruz Portland Cement Co. is doubling the capacity of its plant at Davenport, Santa Cruz county, and will soon be in a position to put out 10,000 bbl. per day. A new corporation, headed by John F. Humberg, vice-president of the Engels Copper Mining Co., has been formed to utilize the cement material in the quarries of the Three Rivers district and to erect a plant, to cost about $4,000,000, about 6 miles from Exeter, Tulare county. The Monolith Portland Cement Co. is enlarging its plant at Monolith, Kern county, and plans to be in a position to supply 6,000 bbl. per day by the end of 1923.

Deutschland Duties Dispute Focused in Baltimore

The wheels of time grind slowly. The U. S. Treasury is now seeking $40,000 of duties claimed on the cargo of the submarine "Deutschland." Circuit Court Judge Rose is hearing the case. A. Schumacher & Co., consignees of the cargo, admit that $10,000 is due. District Attorney Woodcock, conducting the government's side in the proceedings, said the dyestuffs cost $332,000 when bought in Germany. The freight charges on the cargo, Mr. Woodcock said, were $998,000. The government contends that a part of this sum really was part of the purchase price for the dyestuffs and should be included in the duty charges.

London Tallow Auction

At the weekly London tallow auction held May 30, the offerings consisted of 1,524 casks. Sales reached 480 casks and prices realized were 9 pence lower.

Power Developments Proposed for South

Electrochemical and electrometallurgical interests are negotiating for water-power rights on the Pigeon, Clinch, Powell and Holston rivers in western North Carolina and eastern Tennessee. It is believed that the water powers on the western slope of the southern Appalachian range can be developed as successfully as has been done by the Southern Power Co. on the eastern slope. Incidentally, this plan is meeting with opposition from those most interested in Muscle Shoals development, who would like to see these industries locate at that point.

American Cotton Oil to Be Reorganized

A short time ago reports were current to the effect that the American Cotton Oil Co. was to be merged with other cotton oil concerns. Either these reports were not based on facts or negotiations did not work out successfully, as no merger has been made and denials of any contemplated merger came from parties directly mentioned as principals. It is now unofficially reported that plans for reorganizing and recapitalizing the company are being worked out by the officials and directors.

Capital consists of $14,562,300 authorized 6 per cent non-cumulative preferred stock, of which $10,198,600 is outstanding, and $20,237,100 common authorized and outstanding. Funded debt totals $13,500,000, of which $5,000,000 is 20-year 5 per cent bonds due in 1931 which while a direct obligation are not a mortgage. The rest of the funded debt consists of $8,500,000 5-year 6 per cent notes due September, 1924, originally $10,000,000 dated September 10. Under terms of the indenture company agreed to retire $500,000 annually.

Phosphate Rock Shipments in 1922

According to the Department of the Interior, 2,417,883 tons of phosphate rock valued at $10,828,346, was shipped from mines in the United States during 1922, as shown by statistics collected by the Geological Survey. Florida, the leading state, shipped 2,058,593 tons, worth $8,347,522, more than nine-tenths of which was land-pebble phosphate. From Tennessee, 353,309 tons, worth $2,107,382, was reported, including a comparatively small quantity from Kentucky, most of which was brown rock. Small shipments were reported from Idaho and South Carolina.

Electro-Metals Planning California Development

Important developments in electrometallurgy in California are presaged by the announcement that plans have been proposed for the construction of a dam at Ishi Pishi Falls, on Klamath River, at the base of which a 110,000-hp. hydroelectric plant will be erected. This project, sponsored by the Electro-Metals Co., is preliminary to the manufacture and distribution of electrometallurgical products at a point on the Californian seaboard.

The Electro-Metals Co. is equipped to carry the project to a successful technical and business conclusion. Officials include Bulkeley Wells, vice-president and managing director of the Metals Exploration Co.; W. W. Crocker, vice-president of the Crocker National Bank of San Francisco, and William Braden, former president of the Braden Copper Co., of New York. Frank Langford, mining and electrochemical engineer, has made a study of plants and processes in operation in France, Germany, Switzerland and Scotland, and has visited the bauxite deposits of France and Italy, as well as other potential deposits in Ceylon and India. The result is that sufficient data are available to indicate that ore could be delivered at Trinidad or Eureka, Calif., at a lower cost than would be incurred by a railroad haul of a few hundred miles. Construction work on the new dam is expected to commence when the necessary government and state permits have been issued.

Corrosion Data Available in the Near Future

The Chemical Warfare Service's data on the corrosion of metals and materials by acids and alkalis is likely to be available within a few weeks. Major Gibson, speaking for this branch of the service, says:

"This compilation is not being issued by the Chemical Warfare Service, due to the fact that it is desired that those scientists who contributed important parts to the compilation may have full credit for the same, and may be able to present the results of their work before scientific societies, and have published under their respective signatures the papers embodying the data for which each is responsible.

"Papers by Messrs. Calcott and Whetzel, together with a paper by Mr. Whittaker, will be published by the American Institute of Chemical Engineers as a monograph on corrosion. This monograph should cover the essentials of the Chemical Warfare compilation on this subject."

Zinc Institute Seeks Co-operation of Galvanizers

The steps taken at the St. Louis meeting of the American Zinc Institute looking to closer co-operation with the galvanizers are regarded by H. Foster Bain, director of the U. S. Bureau of Mines, as one of the most important outcomes of the meeting. Heretofore the galvanizers have believed that the zinc industry has had little concern for their problems. Now that the Zinc Institute has taken the initiative looking to close co-operation, it is believed that much can be accomplished toward overcoming difficulties that are harmful alike to the zinc industry and to the galvanizers. Each is interested, Mr. Bain believes, in improving the quality of galvanized sheets.

Since the change from iron to steel, galvanized sheets have gradually lost much of the good reputation they once had, Mr. Bain points out. This is due to the fact that a different and a more difficult technical process must be employed. He believes the technology in galvanizing steel sheets can be brought to the same plane of efficiency as was obtained with the use of iron sheets. By the production of a better product, it will be possible, he believes, to increase very greatly the domestic market for zinc.

Stamford Chemists Dine

About forty-five members and guests of the Stamford Chemical Society gathered at the annual banquet on Monday, May 28. Retiring President Stevens outlined the work done during the past year and asked Dr. Getman to tell the visitors of the prizes the society has offered to the high school students in Stamford for essays on chemical subjects. President-elect H. W. Banks then introduced Charles Wadsworth, assistant editor of *Chem. & Met.*, as toastmaster. Addresses were made by Schuyler Merritt, Representative in Congress from the Stamford district, and by Harrison E. Howe of the American Chemical Society.

April Petroleum Output Is Greater Than Consumption

During April, according to the statistics of the Geological Survey, the daily average production of petroleum increased to the high record of 1,937,767 bbl. Daily average imports of crude petroleum, as reported to the Survey by importers (165,500 bbl.), decreased 22,887 bbl.; daily average consumption (1,856,900 bbl.), as indicated by deliveries to consumers, decreased slightly, with the result that for the first time since April, 1922, domestic production of crude petroleum was greater than consumption plus exports of domestic and imported crude petroleum.

Pipe line and tank line stocks of crude petroleum increased 5,889,000 bbl. during the month.

New Yellow Dye Is Produced in U. S.

E. I. du Pont de Nemours & Co. announce the development of an important acid yellow dye, especially noted for its excellent resistance to light, being one of the fastest acid yellows in this respect. The new color is known as Pontacyl Light Yellow 3G, and on account of its good solubility and bright clear shade is an important color for lakes, being well adapted for use in the manufacture of printing and lithographic inks. On paper, it is suitable for dipping, coating and calender coloring.

This dye is one of those which has been imported in important quantities from Europe, and its development here makes it available for American manufacturers as a native color.

Drop in Wholesale Trade

A decrease in the April wholesale trade of 9 per cent from the March record was announced by the Federal Reserve Board last Thursday. The board attributed the loss to seasonal causes and reported that it was not indicative of any serious economic condition. The sales for April this year are 17 per cent greater than those for April, 1922. The greatest sales decreases were in jewelry, shoes, dry goods, clothing and diamonds.

Washington News

Standards for Coal Tars to Be Issued This Month

The Treasury Department expects to issue early in June its official list of standards of strengths of coal-tar dyes and chemicals which is to be the basis of assessment of duty on imports.

A tentative list, specifying approximately 100 dyes, was drawn up a month ago and copies were sent to importers and domestic producers for criticism and suggestion. Copies of the replies have been submitted for study to collectors and appraisers at the leading ports, especially at New York, where more than 95 per cent of the coal-tar products are entered and where the chemical laboratory of the Customs Division is located. Those suggestions which appear to improve the tentative list will be incorporated in the final draft.

The 1922 tariff act provides that coal-tar products be assessed for customs duty according to the weakest strength of similar products imported in commercial quantities prior to July 1, 1914, as many such products now are being imported in stronger concentrations. The list of so-called standards of strength is being compiled for this purpose.

Drawback Allowed on Refined Soya Bean Oil

The customs service of the Treasury Department granted an import drawback last week on refined soya bean oil and soap stock manufactured by the Portsmouth Cotton Oil Refining Corporation, of Portsmouth, Va., from imported crude soya bean oil, the regulations being amended to provide that the manufacturing record and abstract therefrom should show the value of the refined soya bean oil obtained instead of the value of the imported crude soya bean oil used.

Shortage of Caustic Soda in Germany

A new period of shortage of caustic soda in Germany seems to have set in. The Russians and Austrians appear to be willing to pay more for this commodity than domestic buyers in Germany are willing to pay. In turn the Germans are reluctant to buy abroad in the face of the present currency situation.

Services of Chemists in Demand

Practically no unemployment among chemists exists, reports to Washington indicate. Not only are the services of competent chemists in great demand, but the sum of salaries and compensation being paid chemists exceeds by far any previous total ever paid in the history of the American chemical industry.

Tariff Board May Compile Import and Export Statistics

The Tariff Commission has had under consideration the advisability of collecting its own reports on the monthly imports and exports. It is held that by such procedure the totals for our foreign trade would be more readily available to the commission and changes in tariff schedules might be made more promptly in cases where developments would make such changes necessary. This work would be independent of the Commerce Department and would require expansion in the New York office to handle the collection of import and export figures.

Trademark Agreement With South America

Henry P. Fletcher, Ambassador to Belgium, has returned from the conference of American states recently held at Santiago. Mr. Fletcher stated that at the conference an agreement had been reached whereby a United States trademark registered at Montevideo, Uruguay, or at Havana, Cuba, may secure recognition in all of the South American states.

Canada May Appoint Customs Official at New York

A report from Ottawa states that the Minister of Commons has informed the members of the House that the appointment of a Canadian customs officer at New York is still under consideration. The question arose on a discussion of the all-water route from Canadian eastern ports to Vancouver, via the Panama Canal. A Canadian customs officer, it was pointed out, would be needed to supervise transshipment of cargoes broken in bulk at New York.

Tariff Commission Reports to Be Ready This Month

The Tariff Commission has notified the President that reports covering surveys undertaken by the commission to determine the necessity for investigations into different commodities for the purpose of adjusting duties will be completed by the latter part of the month. The report on one commodity is said to be ready now. It is the intention of the commission to take action upon four or five other commodities and to forward reports of its preliminary surveys as completed.

Increased Arsenic Production in Canada

Increasing amounts of white arsenic are being produced at the silver mines of northern Ontario. The fact that the arsenic is bringing high prices has resulted in no little stimulation to the production, it is stated.

Gains in Output of Lead and Zinc Pigments

From figures compiled by the Geological Survey, it is evident that substantial increases in production were made in the cases of lead and zinc pigments in 1922. The figures as issued give totals marketed rather than produced but are relatively true in either case as an index of larger supplies.

Notable increases were made in the sales of all zinc pigments and salts except zinc chloride, but there was a falling off in the average price per ton. The largest output of zinc oxide made in the history of the industry was recorded, the gain amounting to 73 per cent over the output in 1921. The amounts marketed were as follows:

	1921		1922	
	Short Tons	Value Per Ton	Short Tons	Value Per Ton
Sublimed lead*				
White	11,568	$122 61	13,765	$132 94
Blue	463	126 55	972	132.95
Red lead	21,814	156 36	30,509	167 30
Orange mineral	379	240 59	370	224 38
Litharge	41,953	136 84	58,261	152 63
White lead:				
Dry	26,695	140 47	41,598	139 07
In oil	143,634	192 94	153,393	193 80
Zinc oxide	74,329	151.11	128,465	140.07
Leaded zinc oxide	16,103	129 93	19,613	114 80
Lithopone	55,016	121 45	83,360	110.53
Zinc chloride	59,457	59 75	41,627	48 27
Zinc sulphate	3,295	57 47	5,078	49.53

* Includes basic sulphate lead.

Cease and Desist Order Against Philadelphia Company

The Federal Trade Commission has issued its order against Dudley D. Gessler, Philadelphia, Pa., who sells dyestuffs and chemicals under his own name as well as under the name of the Keystone Chemical Co. The Commission's order reads as follows: That respondent, Dudley D. Gessler, and his agents, cease and desist from, directly or indirectly, giving or offering to give to superintendents, foremen or other employees or representatives of customers or prospective customers without the knowledge or consent of their employers, cash commissions, sums of money or other things of value, in order to induce such employees or representatives to purchase, on behalf of their employers, the products of respondent or to recommend such purchase to their employers, or as promised rewards for having induced such purchase by their employers.

Surcharge Rates for Duties Paid in Spanish Currency

Assistant Secretary of the Treasury Moss has issued to collectors of customs the currency conversion values for computing countervailing duties on materials from Spain, imported during the first quarter of the year. The rates of surcharge for duties paid in Spanish silver coins or notes of the Bank of Spain were, for the months indicated, as follows: January, 23.79 per cent; February, 23.39 per cent; March, 23.29 per cent, and April, 24.62 per cent.

Committee Investigates Customs Service at Port of New York

Suggestions for Prompter Release of Goods From Government Custody—Importers Protested Against Delays—Congestion at Appraiser's Stores Has Been Relieved

ERNEST W. CAMP, director of the customs service, was head of a special committee recently appointed to make an investigation of conditions in the various departments of the customs service at the port of New York. This committee was an outgrowth of protests lodged by importers who claimed that serious delays were encountered in securing delivery of goods after the latter had reached the local port. Assistant Secretary of the Treasury Moss accordingly appointed a committee headed by Mr. Camp to analyze the situation and recommend plans for improving the customs service and expediting the movement of goods to consignees.

The committee completed its investigation a week ago and while no public announcement of the finding of the committee has been made, it is said that the report offers several suggestions for the betterment of customs service. The increase in imports undoubtedly has had something to do with the delays in passing goods through the customs service and the new tariff law with its provisions for valuations and ad valorem duties also has slowed up the work of officials, especially in the Appraiser's Stores. It is not expected that the situation will be aided by any additions to the present force, as funds are lacking, but practical suggestions for simplifying the handling of goods through the various departments are expected to be followed by good results. Incidentally it is stated that work in the Appraiser's Stores, where the greatest cause of delay existed, has been arranged so that the period of congestion has passed and fairly prompt deliveries of goods through the customs service are now being made.

Trade Notes

Ralph Black, formerly with E. I. du Pont de Nemours & Co., has joined the sales department of The Kalbfleisch Corporation.

A report from Melbourne states that olive oil guaranteed to be the pure product of olives, made in Mildura, is now obtainable in Victoria, Australia.

Erdoel U. Kohlewertung and Dr. Franz Zernik of Berlin, Germany, have perfected a process for manufacturing an odorless soap from naphthene acid.

The Belgian linoleum industry manufactures almost exclusively for domestic consumption, there being less than 50 metric tons exported during 1922. Production is limited to medium and low grades, while high grades of linoleum are imported. During 1922 Belgium imported 3,675 metric tons, valued at 14,231,775 francs.

The Roessler & Hasslacher Chemical Co., New York, with plant at Perth Amboy, N. J., has presented a claim of $708,864.02 against the German Government for damages sustained during the war.

Sales of pumice stone in this country in 1922 amounted to 50,047 short tons, which compares with 37,108 short tons in 1921.

The annual consumption of casein in Japan is estimated at 500 tons, most of which is imported from Australia. Due to a shortage in Australia this year, casein has been increasing in price. At present it is 0.60 yen per pound Casein is used by the Japanese in the manufacture of art paper.

The Hercules Silica Asphalt Co. has been organized at Sheffield, Ala. The company owns extensive asphalt deposits near Sheffield.

J. L. Boisse has been designated as the New York City representative of the Hermitite Chemical Corporation. The corporation is organized under the laws of Delaware with an authorized capital stock issue of $1,000,000.

Thomas C. Craven, president of the Cumberland Chemical Co., 47 West St., New York, has been indicted by the Federal Grand Jury on charges of conspiring to defraud the government through violation of the Volstead law.

E. A. Brand, secretary of the Tanners' Council of America, has been elected president of the New York Society of Trade Secretaries. Mr. Brand has been prominent in trade association work for a number of years. Prior to directing the work of the Tanners' Council he was engaged in foreign trade promotion work for the government.

J. V. Finamore has organized the Paterson Dyestuff & Chemical Co., with headquarters at 134 Sheridan Ave., Paterson, N. J.

Complaints against several prominent oil companies charging them with forcing their customers into using exclusively their own oil tanks and equipment have just been dismissed by the Federal Trade Commission.

Edward Mallinckrodt, of St. Louis, has given $500,000 to Harvard University for a chemical laboratory.

News Notes

French occupation of the Ruhr now shows a net expense of nearly 10,000,000 francs below receipts. To what extent this favorable balance is due to dyestuff seizures is not revealed.

Improved transportation of newsprint is about to make possible a printed sheet in New York 3 days after the paper is manufactured in the woods of Canada. With available stocks both at the mills and in the publishers' warehouses extremely low, this fast freight service is expected to fill a real need.

The Western New York section of the American Chemical Society held its annual meeting at Canisius College on May 29. W. H. Watkins addressed the meeting and the scientific moving picture "The Einstein Theory of Relativity" was shown.

Sixty-five students in the mining engineering college, University of Pittsburgh, Pittsburgh, Pa., are taking a month's training in field work under the direction of Professors Henry Leighton and R. A. Sommers. Trips of inspection are being made to a number of metallurgical plants.

The Willard Gibbs medal was awarded Prof. Julius Stieglitz, University of Chicago, at a meeting held May 28. The presentation was made by Mr. Converse, founder of the prize. Professor Stieglitz spoke on "The Theory of Color Production in Dyes."

Simplification of asphalt varieties from 102 to 13 was decided on at a conference of producers and consumers held recently in Washington It was decided that the eighty-eight varieties of asphalt used for paving purposes could be reduced to nine, and the fourteen varieties used as brick and stone block fillers could be cut to four.

The Appropriation Committee of the State Legislature, Austin, Tex., is considering an appropriation of $1,526,500 for a College of Mines and Metallurgy. A like fund is to be granted during the second year, or a total of $3,053,000.

The Engineering Section of the National Council will hold its second meeting of the year at Detroit, Mich., in co-operation with the Detroit Safety Council on June 12. Problems of safety in welding and cutting by various methods will be discussed. Industrial sanitation, especially with reference to prevention of infection due to use of cutting oils, will likewise be taken up.

The New York Chapter of the American Institute of Chemistry held its monthly meeting at Mucci's, New York, on May 28. Problems of membership and publicity furnished the topic for the evening's discussion.

Advices from Washington state that customs receipts for the fiscal year up to the last week of May passed the half billion dollar mark and set a record for government revenues from this source.

Development of Sources of Supply for Mangrove Bark and Extract

Bark Found on All Tropical Islands—Manufacture of Extract in Producing Countries Not Sufficiently Developed

A VERY comprehensive report on mangrove bark and extract, with especial reference to sources of supply, has been made by H. M. Hoar, of the Research Division of the Department of Commerce. The report says that mangrove extends as far north and south as the twenty-ninth parallel. It forms a dense growth in patches on the low coasts of all tropical islands. In the United States it occurs along the shores of southern Florida, at the mouth of the Mississippi River and on the coast of Texas. The low coast marshes of Porto Rico produce abundant supplies of mangrove, but, while used locally for both its wood and its bark, the industry has not yet reached an export basis. Mangrove barks constitute the greatest single source of tannin in the Philippines. Analyses prove Philippine barks as rich in tannin content as those used in the cutch factories of Borneo—in fact, the same species of mangrove are common to both regions. Notwithstanding the abundance of mangrove in the Philippines, there are no cutch factories, although the swamp area of one bay in Mindanao covers 25,000 hectares, which, estimating 25 tons of bark to the hectare, would yield a total of 625,000 tons of bark. With a 20-year rotation this should be sufficient to supply a large factory indefinitely. Foreign markets for the bark have not been developed.

Germany Formerly a Large Importer

Prior to the war Germany was active in the exploitation of mangrove bark as a tanning agent. Its main source of supply was East Africa, whose barks seem to be richer in tannin than those of the East Indies. In the former German protectorate the bark was most carefully stripped from the living tree (stripped trees are said to renew their bark in four to six months) under the supervision of the forest department and prepared for export. The export of bark containing less than 45 per cent of tannin was prohibited.

Madagascar exported 21,938 metric tons of mangrove bark in 1913, the greater proportion of which was taken by Germany. In 1917 its exports totaled only 3,410 tons. This decrease was due largely to lack of transportation facilities. Post-war exports, however, have not yet reached the 1913 level. While West Africa has extensive mangrove swamps, no serious attempt at bark collection has yet been made, except in British West Africa, where the industry is well established. Some years ago bark collection was started in Senegal by a French company, which allowed the trees to be cut down without making provisions for replanting, with the result that rapid erosion of the foreshore took place. The government prohibited further exploitation by that company. Stocks of mangrove bark in Burma were practically exhausted in 1919. The problem of working important areas of mangroves in the Andaman Islands is receiving the serious consideration of the authorities.

Manufacture of Extract

The manufacture of extract in the principal countries producing mangrove bark has not been as effectively developed as that of quebracho extract in Argentina and Paraguay. If, however, the industry could be promoted in those countries possessing abundant supplies of mangrove, not only the poorer grades of bark could be utilized but also the leaves, which contain considerable tannin. The leaves are rarely exported, owing to deterioration during transportation. To avoid certain unfavorable chemical changes which the bark undergoes within 48 hours after cutting, it is considered essential to work it up as soon as possible. For this reason the factory should be located in or near the mangrove area. It requires 4 to 6 tons of bark to produce 2 or 2½ tons of cutch. The elimination of waste, greater convenience for shipment and savings in transportation costs should make for further expansion in this industry.

In Dutch and British Borneo the manufacture of extract has become an industry of great importance. The principal factories are located at Pontianak, Rejang, Brunei, Kudat and Sandakan. The latter two are under Scotch control. In 1919 the Netherland Indies exported 3,547 metric tons of mangrove cutch, against 805 tons in 1918.

The extraction of tannin from mangrove bark is a well-organized industry of East Africa. The interest which that region takes in its expansion is manifested in two recent concessions for exploitation of mangrove forests in Portuguese East Africa and Madagascar, both of which contain provisions making it obligatory on the concessionnaires to inaugurate tannin-extract factories within certain specified periods of time. Statistics of exports of this product from East Africa are not available.

The activity of the tannin-extract industry in Colombia was evidenced by its exports to the United States of 2,075,991 lb. of mangrove extract in 1914, the only year for which statistics are obtainable. The principal factories are located at Cartagena and Sinu, each of which has an annual productive capacity of 3,000 tons. With, however, a world-wide reduction in industrial activities during the period of post-war depression, mangrove-extract production in Colombia has been greatly diminished. Both Venezuela and Brazil manufacture mangrove extract for local consumption.

Tannin Content of Mangrove Extract

Mangrove extract is imported in large blocks of a reddish-brown color and has a tannin content ranging from 48 to 72 per cent, according to country of origin. The higher grades come from East Africa and Borneo. Used alone, this extract yields a good, pliant workable leather, but of undesirable color. To modify this objection German tanners blend it with myrobalans valonia, sumac and similar materials the British, with pine, oak and mimosa barks; and in France the favorite mixture is: Mangrove bark, 30 per cent hemlock bark, 40 per cent; oak bark, 20 per cent; and mimosa bark, 10 per cent. The French blend yields a superior grade of leather with an excellent color for general use.

Eimer & Amend Honor Old-Time Employees

Rudolph Zimmermann and Louis Moses, employed by Eimer & Amend for the past 50 years, were tendered a golden jubilee celebration on June 1 at Cavanagh's restaurant. The happy occasion also marked the completion of 25 years or more of continuous service by the following twenty-four employees: E. Kuehnemann, F. Lange, H. Ferber, D. Frattolillo, F. Kuebler, F. J. P. Arndt, H. E. Broestler, Albert Belling, J. R. Cahill, W. Deuvelsdorf, W. Duncan, P. Effertz, William Harres, C. Klinger, T. Schnecke, H. F. Smith, B. E. Ulrich, H. Wachter, W. Then, M. F. Mai, Mary C. Lyden, Mazie Mejo, M. A. Magee and Louise Sormani.

As a token of appreciation the directors presented to each of the two employees completing 50 years of faithful service a check for $5,000. Reviewing an old custom of the house, those completing 25 years of service were presented with suitably engraved gold watches.

August Eimer, president of the company, presided. The other directors who attended the celebration were: Otto P. Amend, vice-president; Carl G. Amend, secretary and treasurer; E. B. Amend, superintendent; A. O. Eimer, assistant treasurer; W. R. Eimer, assistant secretary, and Elenore Amend, director.

Demand for Paraffin in Vera Cruz

Advices from Mexico state that there is a demand in the Vera Cruz district for paraffin to be used in the manufacture of candles. Candles are universally used by the poorer classes for lighting purposes, and the houses of the better classes, although equipped with electric lights, always have a supply of candles on hand for emergencies. A large number of candles are also used in the churches, it being estimated that during normal times candles to the value of 10,000 pesos a month were used in the churches throughout the republic.

Facts and Figures That Influence Trade in Chemical Products

Market Conditions

Current Prices Imports and Exports The Trend of Business

Continued Slow Demand Depresses Prices for Arsenic and Calcium Arsenate

Contract Holders Slow to Take Deliveries—Copper Sulphate Sells at Lower Levels—Imported Caustic Potash Weak—Sal Ammoniac Reduced — Prussiate of Soda Reaches New Low — Bichromates Continue Strong—Permanganate of Potash Irregular but Sells at Advance

REDUCED buying orders and large supplies of imported materials have continued as factors in the local market. This has resulted in further shading of prices and a buyers market is reported for many commodities. Holders of foreign-made oxalic acid have granted concessions and the same holds true for imported caustic potash, prussiate of soda, copper sulphate and sal ammoniac. Arsenic also is listed among the materials which have presented a weak appearance. This appears to be due to failure of consumers to buy in the volume expected and the increase in unsold supplies held by local importers. The position of calcium arsenate also has a bearing on arsenic as the former has not been moving up to expectations and calls for deliveries against contracts are not satisfactory. Predictions of a larger call for arsenic and arsenate, during June, are heard but there is no real indication, as yet, of the accuracy of such predictions.

Many domestic chemicals are holding a firm position. High producing costs, scarcity of labor, sold up condition of producers, and a continued period of active buying, are the principal reasons given for this strength in prices. Among the acids sulphuric and muriatic are very firm due to the unusually large volume of business booked earlier in the season. Acetic acid also is held at the advanced price level which went into effect a few weeks ago. Bichromates have been advanced ½c. per lb. in the past 2 months and some producers are practically out of the market at present. Scarcity of labor undoubtedly has restricted production of bichromates and competition among sellers has been practically eliminated.

Official figures show that exports of chemicals in April were about the same in value as for the month preceding. The soda products figured prominently in the export totals. At present export demand for chemicals is not heavy. Caustic soda, which was shipped to various countries earlier in the year, is still moving well but new orders for June and July shipment are not coming to hand in a large way and prices have eased off but are still too high to arouse interest in markets abroad.

Agricultural chemicals have been featured by placing of contracts for sulphate of ammonia. Nitrate of soda has met with only moderate buying interest and other fertilizer materials have found the usual seasonable conditions prevailing. Potash salts have received considerable attention and large orders are reported as about to be placed.

Acids

Acetic Acid — The various grades have come in for more attention and in different quarters it is reported that the movement to consumers is satisfactory. There has been no change in asking prices, but with producing costs holding up, the situation looks firm as long as buyers show a willingness to take on supplies. Quotations are: 3.38c. per lb. for 28 per cent; 6.75c. per lb. for 56 per cent, and 12@12.78c. per lb. for glacial.

Boric Acid—Call for export is said to be very light but a fairly steady movement to domestic users has kept stocks from accumulating and in general the market is regarded as healthy. The quotations of producers are well maintained at 10@11½c. per lb. with the range varying according to container.

Citric Acid—Different reports are heard about supplies of domestic makes. In some cases it is stated that producers are behind with contract deliveries while other reports say that imported material is of no interest, because of its high price and because domestic goods are offered freely enough to fill consuming requirements. The lowest price heard for imported was 52c. per lb. on spot and shipments are higher than the spot price. The movement of prices seems to depend on demand as a larger buying movement would have a strengthening effect. Domestic is still quoted at 49@50c. per lb.

Lactic Acid—Foreign offerings have been too high in price to be much of a factor and the market is in control of domestic producers. Moderate sized amounts are moving well and values are well maintained with sellers quoting: 4½@5½c. per lb. for 22 per cent dark and 5½@6½c. per lb. for light; 9½@10½c. per lb. for 44 per cent dark and 11½@12½c. per lb. for light.

>
> Easier prices prevailed for copper sulphate, caustic soda for export, benzene and linseed oil, but so far as the index number was concerned the advance in crude cottonseed oil more than offset the declines. The index number was raised 6 points in the past week.

Muriatic Acid—Buying orders have fallen off in volume and a quiet week was reported. Stocks, however, are light and some producers are using their output to take care of contracts. Prices are quoted at 90c.@$1 per 100 lb. for 18 deg. in tanks, with the 22 deg. acid held at $1.75@$2.

Oxalic Acid—Lack of consuming interest has weakened values for imported grades. Holders have been willing to shade prices in order to lessen stocks on hand and there were open quotations at 13c. per lb. Even at the lower prices there was no activity among buyers and only small lots were said to be moving.

Sulphuric Acid—Some of the large consuming trades are not so active at present and call for this acid is less urgent than a short time ago. However, producers, for the most part, have had no chance to accumulate stocks as contract deliveries still take up the bulk of production. Prices are firm at $9.50@$12 per ton for 60 deg. and $15@$16 per ton for 66 deg.

Tartaric Acid—Domestic grades are reported to be strong at an inside price of 37½c. per lb. Imported was rather easy and offerings were on the market at 36½c. per lb. with intimations that on firm bid, odd lots could be picked up under that figure.

Potash

Bichromate of Potash—Buyers are not keen to trade heavily at current prices but sellers are not burdened with stocks and there is no sign of weakness. First hands are holding 11½c. per lb. as an inside quotation and resale material is not a factor in the present market.

Caustic Potash—This material was offered freely by importing firms at 7½c. per lb. and the market for foreign goods has failed to gain any strength. Holdings on spot have been difficult to dispose of and while some shipment quotations have been above the spot selling price, they had no effect on buyers or

sellers. Some factors say that foreign markets are very anxious to keep up volume of sales and selling pressure may keep up for some time.

Carbonate of Potash—Buyers were still able to do 6½c. per lb. in the spot market for 80-85 per cent and forward positions also were offered at that price. Hydrated 80-85 per cent was quiet and easy with 7½c. per lb. given as representing the price for spot goods. On shipments 7½c. per lb. also was quoted but this figure was said to be subject to some shading. Some offerings of 90-95 per cent are said to be on the local market at very attractive prices, in fact it has been quoted as low as the 80-85 per cent.

Permanganate of Potash—While some sellers report prices as irregular with the tone easy, there was an attempt to stabilize values and many sellers were asking 19c. per lb. In fact at least one large lot was sold at the 19c. per lb. level. The shipment market was dull and merely nominal in the absence of buying interest. Many hold that prices will decline considerably from present levels but if anything the market appeared firmer than last week.

Prussiate of Potash—Red prussiate was very quiet and no change of importance was noted. There is some difference in price according to sellers with 65c. to 68c. per lb. covering sellers' views. Yellow prussiate has not been moving well for some time and buyers are interested only when prices are made attractive. The spot market is held at 36@36½c. per lb. with shipments little better than nominal around the spot prices.

Sodas

Soda Ash—New business is not heavy but is fair considering present trading standards. Withdrawals against contracts are going on steadily and this absorbs large quantities. As a result producers are not carrying large stocks. Prices are firm with producing costs said to have advanced since the present price schedule was adopted. Quotations remain at 1.20c. per lb. in single bags for carlots at works and 1.40c. per lb. in bbl., basis 48 per cent.

Acetate of Soda—Only moderate demand has been reported for several weeks and judging from a supply and demand basis there is nothing in sight to bring about a recovery in prices. Sellers offer spot goods at 5½@6c. per lb.

Bichromate of Soda—There is undoubted firmness in the market. Some sellers are not offering freely and some of the leading factors are holding out for 9c. per lb. for carlots with the usual advance for less than carlots. Stocks do not appear to be large in any quarter and reports of diminished output are borne out by the inability of certain sellers to take on orders for prompt shipment. Fair inquiry is reported but higher prices have curtailed interest in large lots.

Caustic Soda—Improvement in export business has not been noted and while prices are subject to some negotiation there was an easier feeling, especially with reference to the so-called outside brands and as low as 3.22½c. per lb., f.a.s. New York, was heard. For standard brands the quotation was held at 3.35c. per lb., f.a.s. Deliveries to domestic consumers remain of good proportions and the price is steady at 2½c. per lb. for carlots, works, basis 60 per cent. For spot material the quotation is 3½c. per lb., flat.

Cyanide of Soda—A large lot of imported cyanide was sold during the week at 20c. per lb. Demand has not been active and the price for imported while generally held at 20½c. per lb. and upward is subject to shading on desirable business. Domestic makers are holding their goods at 22@23c. per lb.

Fluoride of Soda—Sales of imported goods were reported at 9c. per lb. with 9@9½c. per lb. covering the prices asked. The market as reported was inactive with scattered inquiry. Domestic fluoride is not a factor in the local market and is quoted at 10½@11c. per lb.

Prussiate of Soda — Producers of domestic grades have announced a price of 16c. per lb. for June deliveries. Demand has fallen off and weakness in price has failed to bring about any large buying. Imported prussiate was decidedly weak and as low as 15c. per lb. could be done according to local handlers. Competition between domestic and foreign sellers is keen and the market is not in a position to withstand selling pressure.

Sulphide of Soda—There is a firm tone to the market for domestic material and fused is well maintained at 4½c. per lb. and broken at 5½c. per lb. Crystals are in small supply and are quoted at 2¾c. per lb. Imported sulphide is less firm in tone and prompt shipment is reported as available at 3½c. per lb. For spot imported the lowest figure heard is 3.60c. per lb.

Miscellaneous Chemicals

Arsenic—The fact that buying has not improved to the extent expected is a disturbing factor. Large lots had been imported in recent weeks and a good part of these arrivals were not sold but were held to take care of the demand which had been predicted would follow. So far this demand has been far from as heavy as predicted. Some holders of contracts also are slow in ordering out goods and prices are sagging as certain holders get tired of carrying stocks. There were offerings on spot as low as 14c. per lb. and even this price was not considered strong by some members of the trade. Domestic arsenic is passing direct to consumers and has not been much of a factor in the spot market. Prices for domestic have been under the levels openly quoted for spot material. Producers quote shipments over the last half of the year at 11c. per lb. and July shipment at 12½c. per lb.

Bleaching Powder—While new business is not heavy there is a steady delivery against old orders and producers are not forced to press matters in view of the ready absorption of stocks. Prices are steady at 1.90c. per lb. for large drums at works.

Cream of Tartar—The market is easy in tone with imported material offered freely and buyers are not taking on much. Spot prices are 25½@26c. per lb. and forward positions are offered about 1c. per lb. under the spot levels.

Calcium Arsenate—Very little if any improvement in demand was reported last week and despite reports that June would bring out a better call for stocks, the market has been easy in tone. The open quotation is given at 16c. per lb. but this could be shaded materially and the actual trading basis was largely a matter of private terms between buyer and seller.

Copper Sulphate—A sale of imported copper sulphate was reported at 5c. per lb. There is very little stability to prices for goods of foreign origin and while some holders are refusing to sacrifice, others are willing to meet buyers' ideas in order to get rid of stocks. Open quotations for imported in the latter part of the week ranged from 5.10c. per lb. to 5½c. per lb. with the range depending on seller and make. Domestic goods were held at 5.90c. per lb. for large crystals.

Chloride of Barium—The market is suffering from the lack of interest taken by consumers and prices are not holding any too steady. Quotations are given at $85@$90 per ton for spot or futures, but reports are heard to the effect that bids under the inside figure have found acceptance.

Formaldehyde—First-hands reported a steady market and maintained prices at 15@15½c. per lb., the inside figure obtaining on round-lots. The demand was moderate only, and it was reported that a few odd lots held by second-hands could have been secured at 14½@14¾c. per lb.

Sal Ammoniac—Further reductions in price were heard for imported goods and 6c. per lb. was given as the figure at which buyers could operate. Domestic makers were holding nominally unchanged at 7½@7¾c. per lb. with gray at 8@8½c. per lb. f.o.b. works.

Alcohol

Producers reported a fair volume of business and prices for the denatured ruled steady at the recent advance. Several small parcels of denatured arrived at New York from the West Indies. The special grade, formula No. 1, held at 38c. per gal. in drums, the customary premium obtaining for wooden containers. The formula No. 1, completely denatured, held at 43c. per gal., in drums. The market for ethyl spirits was nominally unchanged on the basis of $4.70 per gal. for the 190 proof, U. S. P. Methanol was unchanged, closing at $1.18 per gal. on the 95 per cent and $1.20 on the 97 per cent.

Coal-Tar Products

Spot Phenol and Naphthalene Unsettled on Freer Offerings—Benzol Easier—Solvent Naphtha Holds Firm

THE volume of new business placed in the coal-tar division of the chemical market did not come up to expectations and with selling pressure in evidence in some of the items in the list prices appeared to be more or less unsettled. Interest centered in phenol and scattered lots held by second hands sold at prices ranging from 45@50c. per lb. Rumors were about to the effect that new production would soon come out at comparatively low prices and this frightened some holders of spot goods. In naphthalene the market was easy and sales of flake were put over at 8¼c. per lb. The recent reduction in gasoline finally did bring out a lower range of prices on benzene and from all indications offerings were plentiful at the recently reduced level. In solvents, however, the situation continues to favor sellers and while no price changes were announced some traders felt that a higher trading level was not at all out of the question. Salicylic acid was inactive and prices in several quarters were considered barely steady. Several shipments of pitch arrived from English ports during the past week, but, upon investigation, it was learned that this material was not a coal-tar product.

According to official figures exports of coal-tar products from the United States for the first quarter of the year were valued at $2,761,118, which compares with $1,810,331 for the corresponding period a year ago. Most of the exports consisted of crudes. Producers say that domestic business over the first quarter also gained considerably, contrasted with the corresponding period a year ago.

Aniline Oil—Trading last week was inactive, but leading makers continued to quote the market as steady on the basis of 16c. per lb. on carload lots, immediate and nearby delivery.

Aniline Salt—While several handlers held out for 23½@24c per lb. in the salt, others offered supplies freely at 23c. per lb. Demand was quiet.

Benzaldehyde—With not much available on spot the market ruled steady. The lull in trading had little or no influence upon sellers, who continued to quote on the basis of 75c. per lb., nearby delivery.

Benzene—Increased competition with gasoline was reflected in easier prices on benzene and it develops that leading interests lowered prices a short time ago. The 90 per cent grade was offered by leading producers at 25c. per gal., tank cars, f.o.b. works, with the pure at 27c. per gal., in tank cars, f.o.b. works. The pure in drums, on spot, closed nominally at 30@32c. per gal.

Creosote—There were offerings of the 25 per cent for immediate shipment at 26c. per gal. Demand was slow and prices were barely steady.

Cresylic Acid—The market for cresylic was unsettled all week so far as second-hand offerings were concerned and closing prices were more or less nominal, depending upon the seller and quantity. On the 97 per cent grade there were offerings on spot at $1.15 per gal. Domestic producers had nothing to offer except on contract to regular consumers. There were no new developments in connection with the tariff situation.

Dimethylaniline—Producers reported a steady market for this intermediate, the output apparently being well taken care of. Prices were repeated at 42@43c. per lb., prompt and nearby delivery.

Naphthalene—An irregular market was witnessed on flake for immediate delivery and offerings late in the week could be located at 8¼c. per lb. In fact several lots sold at this figure. Demand was inactive, the weakness in foreign crude restricting business. New contract prices by domestic producers were not announced, but it was intimated that the quotations will show a higher trading level contrasted with last year's contract basis. Imported crude for shipment settled around 3¼@3½c. per lb.

Phenol—Sales of U.S.P. phenol went through in outside channels, for immediate delivery, as low as 45c. per lb., which compares with 50c. per lb., the settling price a week ago. The market on re-sale goods was irregular and prices at the close were considered to be little more than nominal. It was rumored that new production could be purchased for deferred delivery at prices considerably below 28c. per lb., and this kind of talk brought out a feeling of uneasiness and restricted business to a minimum.

Salicylic Acid—No further price changes were announced, but factors reported a quiet market with the undertone barely steady, due, in part, to the easier feeling in phenol. One prominent producer offered the U.S.P. grade at 45c. per lb., while others named a price of 40c. per lb. Some traders raised some questions about the 40c. quotation, claiming that round-lots could not be obtained at this figure. However, as no inquiry developed for round-lots the "argument" could not be settled.

Solvent Naphtha—Large producers say that there is a ready market for all of the solvent naphtha available and they regard the general situation as firm. Nominal quotations were repeated at 27@32c. per gal., the inside figure prevailing on tank car business.

French Chemist Claims He Can Dissolve Coal

A process has been devised whereby coal can be dissolved much in the same manner as sugar dissolves in water, according to an announcement made before the Paris Society of the Chemical Industries by A. Kling, director of the Parisian Municipal Chemical Laboratory. The experiments were conducted in co-operation with Florentin and Pictet. Dr. Kling contends that they succeeded in suspending a pure pulverized coal in carburetted hydrogen and by subjecting it to pressure and heat a solution resulted from which motor fuels and other products can be made.

What Is Standard Newsprint?

The definition of standard newsprint, made necessary for the purpose of admitting that commodity under the free list of the tariff act, has been difficult to make. Newspaper interests have protested the tentative formula suggested by Secretary Mellon. This formula defined standard newsprint as a commodity weighing approximately 32 lb. to the ream, 24 x 36 in., and composed of a mixture of mechanically ground wood pulp and sulphite pulp in the relative proportions of 80 per cent and 20 per cent. Clauses for taking care of slight variations were also included. It is expected that despite the delay occasioned by the protest the final ruling will soon be issued.

Vegetable Oils and Fats

Linseed Dull and Easier—Crude Cottonseed Steady—China Wood Declines—Tallow Slightly Higher

BUSINESS showed no improvement and an easier feeling prevailed in most quarters of the vegetable oil trade. Crude cottonseed was a shade firmer than a week ago, while tallow actually sold at a slight advance, but these developments were more than offset by the unsettlement in linseed, china wood, coconut and palm oils. Traders were interested in the oil seeds situation, especially the new crop developments in cotton. Advices from Europe indicated that business in vegetable oils was anything but satisfactory. Easier prices were reported in hogs, in the western markets, which was reflected in the unsettled market for lard.

Linseed Oil—Demand was dull and with seed markets lower the undertone at the close was easy. There were offerings of prompt shipment oil on the basis of $1.12 per gal., carload lots, cooperage included, but most traders in the domestic product continued to quote $1.14 per gal. On second-half of June business, however, several crushers stood ready to trade at $1.12 per gal., with a possibility of shading this figure on a firm bid. July oil was offered at $1.04 per gal., in cooperage, with August forward at $1 per gal. Large consumers showed no buying interest in futures. The absence of new business will do much to ease the supply situation and it seems altogether probable that stocks of oil will be something like normal in another month or so. During the past week foreign oil for prompt shipment from New York was offered on the ex-dock basis of $1.02 per gal., in cooperage, duty paid, one lot of approximately 1,000 barrels pressing on the market. English oil for June shipment from the other side was offered freely at $1.02 per gal. landed weights, duty paid, c.i.f. New York. London cables reported dull trading in all of the British as well as Continental markets. Offerings of Argentine seed increased, while Indian sellers also appeared more anxious for business. During the week previous 28,000 bushels of Indian seed were shipped to the United States. The stocks of flaxseed at Minneapolis increased to 19,236 bushels in the past week, which compares with 9,396 bushels a week ago and 62,517 bushels on the corresponding date a year ago. Minneapolis reported dull trading in linseed meal, the market settling around $37 per ton. New York exporters said that foreign inquiry for cake was absent and prices of $33@$34 per ton f.a.s. were wholly nominal.

Cottonseed Oil—The option market on the Produce Exchange was a narrow affair, yet prices held remarkably steady considering the small volume of sales and the irregularity in competing oils and fats. The developments in cotton were not considered favorable and the speculative element refused to operate in the new crop months on an extensive scale. The spot position in prime summer yellow oil settled around 11.80c. per lb., bid, which compares with a 10c. market on October and 9c. for December. Traders look for no important movement in old crop prices, notwithstanding the fact that the statistical position is extremely tight. Cash trade in oil was inactive, while business in lard compound also was slow. Several cars of crude oil actually sold at 10c. per lb., f.o.b. mills, an advance of ¼c. from the nominal price named a week ago. The offerings of crude were scanty. Nothing was heard in connection with new crop crude oil. Bleachable oil for prompt shipment from Texas common points closed nominally at 10½c. per lb.

China Wood Oil—The feature in the market was the easier position of futures. There were offerings of July-August-September shipment from the Pacific coast at 19c. per lb., but this failed to bring out any buying interest. Spot oil in New York was available at 25½@28c. per lb., the inside figure obtaining on a tank car.

Coconut Oil—Several cars of Ceylon type oil sold for prompt shipment from New York at 8⅞c. per lb., which price prevailed up to the close. Trading, taken as a whole, was inactive, and the undertone easy in sympathy with copra. On the Pacific coast there were offerings of nearby oil on the tank car basis of 8c. per lb., with forward material available at 7¾c. per lb. Copra was offered at 4⅝c. per lb., c.i.f. Pacific coast ports, and at 5c. per lb., c.i.f. New York. It was reported that buyers' views were nearer 4½c. per lb., c.i.f. coast.

Corn Oil—The market for crude was up a little in the west, last sales going through at 9½c. per lb., f.o.b. point of production. This quotation represents a gain of ¼c.

Olive Foots—There were sellers at 9@9½c. per lb., spot, with business dull. On futures the market for prime green settled at 9c. asked.

Palm Oils—The market was inactive, but the slight recovery in tallow brought out a better feeling. Lagos settled nominally at 7⅞@7½c. per lb., with Niger at 7@7⅛c. per lb., the price depending upon the position.

Menhaden Oil—Chesapeake Bay advices indicate that only one-half of the fleet of 46 boats took part in the first week's fishing operations. A fair catch was reported. The market for oil was dull so far as new business was concerned, but traders continued to quote 50c. per gal., tank cars, f.o.b. factory.

Tallow and Greases—The sale of several hundred drums of extra tallow was put through about a week ago at 7⅝c. per lb., an advance of ⅛c. Offerings were not pressing on the market, but inquiry at the advance fell away quite perceptibly. Soapers refused to anticipate their wants. Yellow grease was steady, closing nominally at 7c. asked on low acid stock. Oleo stearine held at 9c., the last trading basis.

Miscellaneous Materials

Glycerine—Reports on the condition of the market were conflicting, but most traders regarded the situation as a little more favorable, especially where the C. P. grade was concerned. Some contract business was put through around 17c. per lb., in drums, carload lots. In the middle west C. P. was offered at 16½c. On a brand not so well established there was a possibility of doing 16½c., New York. The dynamite grade was inactive and nominally unchanged at 15¾@16c. per lb. Soap-lye crude, basis 80 per cent, closed at 11c. asked, loose, New York. An odd car or so sold during the week at concessions. Western producers held out for 10½c. on the soap-lye. Saponification, 88 per cent, closed nominally at 12¼@12½c. per lb., loose, with no sales reported.

Naval Stores—The market developed further weakness and toward the close spirits of turpentine stood at $1.06@$1.08 per gal. Demand was quiet, both in an export and domestic way. Southern markets were subjected to a little pressure. Rosins did not change much, the lower grades closing at $5.95@$6.10 per bbl.

Chalk—Importations have been heavy, but demand continues satisfactory and quotations ruled steady at $5@$5.50 per ton, cargo basis, c.i.f. New York.

Shellac—Early in the week prices went off a little, but later offerings were not so plentiful and with Calcutta advices slightly firmer the market steadied a little. Buying was hand-to-mouth in character and traders appeared to show no desire to book ahead under present conditions. T. N. on spot settled at 58@59c. per lb. Bleached, bonedry, closed at 72@73c. per lb. Superfine orange was offered at 64@65c. per lb.

Lithopone—Domestic producers admit that business has slowed up a bit, but with no change in basic material they continue to quote from 7@7¼c. per lb., carload lots, the inside figure obtaining for the material put up in bags.

White Lead, Etc.—The metal held at 7.25c. per lb., New York. Since the reduction in pig lead prices, which occurred about a month ago, corroders have not altered prices for the pigments. Business in white lead has been quite active and this accounts for the steady position of the leading producers. Dry white lead, basic carbonate, held at 9⅝c. per lb., in casks, round-lots. Dry red lead held at 11⅝c., in casks. Litharge was unchanged at 10¾@11c. per lb.

Zinc Oxide—Prices were repeated at 8c. on the lead free and 7@7¼c. on the 10@35 per cent leaded, American process oxide. French process held at 9⅝c. on the red seal, in bags. The market was steady.

Financial Notes

Belgo Paper Co., of Montreal, which is passing into Canadian control, shows average net earnings after maintenance and repairs of $1,742,570 for the past four years, and $1,989,054 for eight months ended April 30.

American Druggists Syndicate has notified stockholders change in par value of capital stock from $10 to $50, recently authorized at a special meeting of stockholders, cannot be carried out, owing to fact publication of notice has not been legally complied with. This will necessitate another meeting to properly authorize the change, for which due notice will be given.

Glidden Co. and subsidiaries for six months ended April 30, 1923, show net profit of $445,106, after interest, federal taxes, reserve for contingencies and depreciation. Company states that fiscal year begins November 1, and consequently above statement covers operations during five cold and unseasonable months of the year. Business for the last six months covers the real paint and varnish consuming months.

Formal transfer of Acme Cement Plaster Mills at Acme has been made to the Certain-teed Products Corp. of New York.

Special meeting of stockholders of Standard Oil Co. of New York, scheduled for last week, to approve proposed increase in authorized capital stock from $225,000,000 to $300,000,000 of $25 par, was not held as not sufficient proxies were received to comply with statutory provisions.

The balance sheet of the Pacific Oil Co., covering operations in 1922, shows a surplus of $11,792,226 after depreciation, depletion, federal taxes, etc., equivalent to $3.37 a share on its 3,500,000 shares of outstanding no par value stock. In 1921 net income amounted to $16,261,292, or $4.64 a share on the stock.

The United Dyewood Corporation reports for the past year's operation a balance of $1,816,212 available for dividends on the common stock. This is equivalent to $13.04 a share on the 139,183 shares outstanding.

The Chino Copper Co. reports for the first quarter of 1923 total income, exclusive of depreciation and federal taxes, of $405,611, equal to 45c. a share on the 900,000 shares of capital stock of $5 par value outstanding. This compares with total income of $182,629, or 20c. a share, in the final quarter of 1922.

The American Copper Mining Co. has announced that on and after June 30, 1923, it would redeem all its outstanding 7 per cent, 10-year secured gold bonds, series B, at a premium of 3 per cent.

Imports at New York

May 25 to May 31

ACIDS—89 dr cresylic, London, Celluloid Co., 280 bx. formic and 30 csk. oxalic, Rotterdam, W. R. Greeff & Co., 183 dr cresylic, Liverpool, Order, 200 keg. tartaric, London, Russian Produce Co, 100 csk. citric, Palermo, R F Downing & Co, 150 csk, Palermo, W. Neuberg, 140 csk tartaric, Palermo, Order, 100 csk citric, Palermo, Order

AMMONIUM—20 pkg. carbonate, Liverpool, Brown Bros & Co.

ALCOHOL—200 bbl. Arecibo, C Estena

ARSENIC—51 csk, Liverpood, Order, 100 bbl, Tampico, Am Metal Co.

ASBESTOS—1239 bg., Southhampton, W. D Crompton & Co

BARIUM BINOXIDE—63 cylinders, Havre, Mallinckrodt Chem Works.

CAMPHOR—100 cs., Hamburg, A Oehse Co

CASEIN—298 bg, Bombay, Casein Mfg Co, 163 bg, Bombay, Order, 417 bg, Buenos Aires, Equitable Trust Co., 1667 bg, Buenos Aires, Kalbfleisch Corp, 163 bg, Havre, N. Y Trust Co

CERIUM FLUORIDE—40 csk, Hamburg, Pfaltz & Bauer.

CHEMICALS—12 cs, Antwerp, Vandegrift & Co, 107 pkg., Rotterdam, Order, 90 csk, Bremen, Roessler & Haaslacher Chem Co, 38 csk, Bremen, Order, 120 csk, Newcastle, E Hills Son & Co, 32 bbl, Hamburg, A Murphy & Co, 45 bbl., Hamburg, Roessler & Hasslacher Chem Co

COLORS—22 cs. dry, London, R F Downing & Co.; 10 csk., Liverpool, Order, 4 csk aniline, Havre, Irving Bank-Col. Trust Co, 12 pkg do., Havre, W Sykes & Co, 6 csk, Havre, B Bernard, 5 csk, Havre, H R Ackerman, 22 csk, Havre, Geigy Co, 129 csk., Havre, Ciba Co, 2 bbl, Antwerp, B Bernard, 12 pkg Havre, Irving Bank-Col. Trust Co, 9 csk, Rotterdam, H A. Metz & Co, 6 pkg, Rotterdam, Organic Products Co., 21 cs, Hamburg, E C Foster, 40 csk, Hamburg, Kuttroff, Pickhardt & Co, 6 csk, Hamburg, H A. Metz & Co., 10 csk., Hamburg, H R John, 10 csk, Hamburg, Equitable Trust Co, 13 csk dry, Southampton, Stanley Doggett, Inc, 126 csk aniline, Havre, Ciba Co, 26 bbl dry, Havre, Reichard-Coulston, Inc, 11 csk earth Hamburg, Reichard-Coulston, Inc.

COPPER SULPHATE 100 csk, Hamburg, A. J Marcus

COPPER OXIDE—50 dr., Hamburg, American Metal Co, 11 csk, Newcastle, Int'l Comp Co

CREAM TARTAR—10 bbl., Bordeaux, R. W Greeff & Co

COPRA 100 bg, Santiago, Order, 477 bg, St Anns Bay, Order, 152 bg., Morant Bay, Franklin Baker Co

DEGRAS—90 bbl. Bordeaux, Order, 60 csk Bremen, C. H Hilbert, 150 bbl., Hull Nat'l City Bank

DIVI-DIVI—75 bg., Maracaibo, Int'l Forwarding Co

DYESTUFFS—2 csk, Southampton, Am. Exchange Nat'l Bank, 3 csk, Havre, Carbric Color & Chem. Co,

FERROSILICON—511 csk, Stockholm, C. Hardy & Ruperty, 328 cs, Skien, Norwegian Nitrogen Products Co; 320 cs, Skein, Order

FUSEL OIL—11 csk, Havre, Order, 19 dr., Dunkirk, Guaranty Trust Co.; 16 dr, Dunkirk, Mass & Waldstein.

GLYCERINE—20 csk, Bordeaux, Order; 35 csk, Havre, Thornett & Fehr.

GUMS—58 bg tragacanth, Bombay, Goschens & Cunliffe, 486 bg Persian, 140 bg karaya and 180 bg. arabic, Bombay, Guaranty Trust Co; 140 bg karaya, Bombay, Brown Bros & Co, 68 bg. tragacanth and 560 bg. karaya, Bombay, Order; 105 bg copal, Antwerp, Brown Bros & Co, 409 pkg do, Antwerp, Chem. Nat'l Bank, 915 bg. copal, Antwerp, Order; 320 bg. copal, Antwerp, H W. Peabody & Co.; 30 bg copal, Liverpool, Order

IRON OXIDE—18 csk, Liverpool, J. A McNulty; 70 csk, Liverpool, Reichard-Coulston, Inc, 17 csk., Liverpool, L. H. Butcher & Co

MANGROVE BARK—1,352 bg., Hamburg, Bingham & Co.; 8,000 bg., Hamburg, Bingham & Co

MINERAL WHITE—200 bg., Hull C. B. Chrystal & Co; 1,200 bg., Hull, Hammill & Gillespie.

MYRABOLANS—2,312 bg, Bombay, Fourth Atl Nat'l Bank; 4,766 bg., Bombay, Order; 9,720 pkt., Calcutta, Nat'l City Bank; 15,006 pkt., Calcutta, Standard Bank of South Africa, 4,480 pkt., Calcutta, Order

NAPHTHALENE—660 bg., Liverpool Martin & Co.; 1,162 bg., Liverpool, Order

OILS—**Castor**, 100 bbl., Hull, Order. **Coconut**—114 pipes, Cochin, Volkart Bros, 94 hhds, Cochin, Order. **Cod**—100 bbl., Aberdeen, Order. **Linseed**—285 bbl., Rotterdam, Thomas Tucker & Co.; 146 bbl., Rotterdam, Lockwood & Co; 200 bbl., Southampton, Hudson Oil Co.; 867 bbl., Hull, National City Bank, 897 tons (bulk) Hull, Order **Rapeseed**—1,000 bbl., Liverpool, Vacuum Oil Co.; 100 bbl., Hull, National City Bank; 500 bbl, Hull, Vacuum Oil Co, 425 bbl., Hull, Order. **Sesame**—100 dr., Rotterdam, Order. **Palm**—128 csk., Liverpool, African & Eastern Trading Corp, 100 csk., Liverpool, E. F. Drew & Co, 496 csk, Liverpool, Order, 158 csk., Rotterdam, J Holt & Co., 37 csk, Liverpool, Standard Bank of S. Africa, 34 csk. and 48 bbl., Liverpool, D. Bacon, 140 csk., Liverpool, Order. **Peanut**—300 bbl., Liverpool, E F Drew & Co; 200 bbl., Hull, E. F Drew & Co. **Soya Bean**—325 bbl., Liverpool, I R Boody & Co. **Whale**—23,200 bbls, Montevideo, Order.

OIL SEEDS—**Castor**—7,130 bg, Bombay, Volkart Bros., 1,358 bg., Bombay, Order; 5,464 bg., Coconada, Volkart Bros. **Linseed**—2,563 bg., Montevideo, Order, 17,852 bg, Rosario, Order, 44,730 bg, San Lorenzo, Order, 35,884 bg., Rosario, Order; 16,408 bg, Buenos Aires, Spencer Kellogg & Sons

POTASSIUM SALTS 2,000 bg manure salt, Hamburg, Order, 2,000 bg, sulphate, Order, 35 dr caustic, Bremen, Innis, Speiden & Co, 1,120 bg., muriate, Bremen, A. Vogel, 3,500 bg, sulphate, Hamburg, Order, 71 csk. carbonate, Hamburg, Peters, White & Co, 25 dr. permanganate, Hamburg, Order.

PITCH 600 bbl., Hull, Tunley & Co., 100 bbl., Hull, Order.

PYRIDINE—11 dr, Liverpool, R W. Greeff & Co, 9 dr, Liverpool, Order

QUEBRACHO—50,569 bg, Buenos Aires, Tannin Corp, 1,074 bg., Buenos Aires, Fourth At'l Natl Bank.

QUICKSILVER—250 fl., London, Order.

QUINIDINE—77 dr, Rotterdam, R. W. Freeff & Co.

SHELLAC—600 bg., Calcutta, Philadelphia Nat'l Bank, 250 bg., Calcutta, Order, 100 cs, London, Order, 71 bg., Havre, Standard Bank of South Africa, 35 bg, Hamburg, Order, 740 bg, Calcutta, Brown Bros. & Co, 10 bg, Calcutta, Lee, Higginson & Co., 50 bg, Calcutta, Bank of Brit. West Africa, 100 bg, Calcutta, N Y Trust Co., 46 bg., Calcutta, Bank of Montreal, 2,140 pkg., Calcutta, Order; 422 bg, Calcutta, Anglo So. Am. Bank; 537 bg., Calcutta, Bank of N Y & Trust Co.; 500 bg refuse, Calcutta, Bank of Manhattan Co, 150 bg, Calcutta, First Nat'l Bank of Boston; 550 bg garnet, Calcutta, Bank of America, 50 bg., Calcutta, London & Braz Bank; 50 bg, Cal-Calcutta, Mech. & Metals Nat'l Bank, 500 bg, Calcutta, Chase Nat'l Bank; 1,002 bg., Calcutta, Order

STARCH—250 bg potato, Rotterdam, Chatham & Phenix Nat'l Bank.

SODIUM SALTS—168 cs. cyanide, Havre, C. Hardy & Ruperty; 250 cs cyanide, Havre, Meteor Products Co, 243 cs, Havre, Asia Banking Corp.; 34 csk prussiate, Liverpool, H J Baker & Bros., 113 csk. hydrosulphite, Rotterdam, H. A Metz & Co., 4,115 bg. and 343 csk. synthetic nitrate, Skien, Order; 25,089 bg. nitrate, Antofagasta, Wessel, Duval & Co., 92,317 bg nitrate, Tocopilla, Wessel, Duval & Co., 15,766 bg. nitrate, Mejillones, W. R. Grace & Co; 29 dr. perborate, Hamburg, International Acceptance Bank; 55 dr sulph.-hydrate, Hamburg, C. S. Grant & Co

SUMAC—200 bl, Palermo, Order

TANNING EXTRACT—30 csk., Liverpool, Brown Bros. & Co.

TARTAR—100 bg, Bordeaux, Order

TURMURIC—369 bg, Aleppy, Darragh, Small Co; 1,400 bg., Cochin, Order.

ULTRAMARINE—16 csk, Liverpool, Fezandie & Sperrle

WHITING—5125 bg, Dunkirk, Taintor Trading.

WAXES—32 bg. bees, London, Order; 20 bg. bees, Rio de Janeiro, London & Brazilian Bank; 18 bg., Rio de Janeiro, Storrs Mica Co.; 34 pkg. bees, Havana, Order; 100 cs spermacette, Glasgow, Order

ZINC OXIDE—34 csk., Liverpool, L. H. Butcher & Co.

ZINC WHITE—20 bbl, Southampton, Houbegart, Inc.

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Gray, gran., casks.........	lb.	.08 -	.09
Salsoda, bbl.. 100	lb.	1.20	1.40
Salt cake (bulk)........	ton	26.00 -	28.00
Soda ash, light, 58% flat, bags, contract... ... 100	lb.	1.60 -	1.67
Soda ash, light, basis, 48%, bags, contract, f.o.b.. wks... 100	lb.	1.20 -	1.30
Soda ash, light, 58%, flat, bags, resale . . 100	lb.	1.75 -	1.80
Soda ash, dense, bags, contract, basis 48% 100	lb.	1.17½-	1.20
Soda ash, dense, in bags, resale . . 100	lb.	1.85 -	1.90
Soda, caustic, 76%, solid, drums, f.a.s... 100	lb.	3.22½-	3.35
Soda, caustic, basis 60%, wks, contract. . 100	lb.	2.50 -	2.60
Soda, caustic, ground and flake, contracts 100	lb.	3.80 -	3.90
Soda, caustic, ground and flake, resale. ... 100	lb.	3.72½-	....
Sodium acetate, works, bags..	lb.	.05½-	.06½
Sodium bicarbonate, bbl .. 100	lb.	2.00 -	2.50
Sodium bichromate, casks.. .	lb.	.09 -	09½
Sodium bisulphate (niter cake)	ton	6.00 -	7.00
Sodium bisulphite, powd., U.S.P., bbl.	lb.	.04½-	.04½
Sodium chlorate, kegs...... .	lb.	.06½-	.07
Sodium chloride	long ton	12.00 -	13.00
Sodium cyanide, cases	lb.	.20 -	.23
Sodium fluoride, bbl. .	lb.	$0.09 -	$0 10½
Sodium hyposulphite, bbl..	lb.	.02½-	.03
Sodium nitrite, casks . .	lb.	.08 -	.08½
Sodium peroxide, powd, cases	lb.	.28 -	.30
Sodium phosphate, dibasic, bbl.....	lb	.03½-	.04
Sodium prussiate, yel. drums	lb.	.15 -	.16
Sodium salicylic, drums	lb.	.47 -	.52
Sodium silicate (40°, drums) 100	lb.	.80 -	1.25
Sodium silicate (60°, drums) 100	lb.	2.00 -	2.25
Sodium sulphide, fused, 60-62% drums.... . .	lb.	04½-	.04½
Sodium sulphite, crys, bbl	lb	.03½-	.03¾
Strontium nitrate, powd., bbl.	lb	.12½-	.13
Sulphur chloride, yel drums.	lb	04½-	.05
Sulphur, crude	ton	18 00 -	20.00
At mine, bulk	ton	16 00 -	18 00
Sulphur, flour, bag .. . 100	lb.	2.25 -	2.35
Sulphur, roll, bag ... 100	lb.	2.00 -	2.10
Sulphur dioxide, liquid, cyl. .	lb.	.08 -	08½
Talc—imported, bags .. .	ton	30 00 -	40.00
Talc—domestic powd., bags.	ton	18.00 -	25.00
Tin bichloride, bbl. .	lb.	.12½-	.13½
Tin oxide, bbl . ..	lb.	.48 -	
Tin crystals, bbl .	lb	.35½-	.36
Zinc carbonate, bags. .	lb.	.14 -	.14½
Zinc chloride, gran, bbl.	lb.	.06½-	.06¾
Zinc cyanide, drums.. ..	lb.	.37 -	.38
Zinc oxide, , lead free, bbl..	lb.	.08 -	.08½
5% lead sulphate, bags ...	lb.	.07½-	......
10 to 35 % lead sulphate, bags .	lb.	.07 -	.....
French, red seal, bags . .	lb.	.09½-	. . . .
French, green seal, bags .	lb.	.10½-	.....
French, white seal, bbl	lb	.12 -	. . .
Zinc sulphate, bbl.... . 100	lb.	2.50 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl....	lb.	$0 65 -	$0.80
Alpha-naphthol, ref., bbl. .	lb.	.75 -	.90
Alpha-naphthylamine, bbl....	lb.	35 -.	37
Aniline oil, drums	lb.	.16 -	.16½
Aniline salts, bbl.	lb.	.23 -	24
Anthracene, 80%, drums... .	lb.	.75 -	1.00
Anthracene, 80%, imp., drums, duty paid... ...	lb.	.70 -	.75
Anthraquinone, 25%, paste, drums .	lb.	.70 -	.75
Benzaldehyde U.S.P, carboys	lb.	1.40 -	1.45
tech, drums . .	lb	75	80
Benzene, pure, water-white, tanks and drums .	gal.	.27 -	.32
Benzene, 90%, tanks & drums	gal.	.25 -	.30
Benzene, 90%, drums, resale..	gal.	.28 -	.32
Benzidine base, bbl.	lb.	.85 -	.90
Benzidine sulphate, bbl .. .	lb.	.70 -	.75
Benzoic acid, U.S P, kegs . .	lb.	.72 -	75
Benzoate of soda, U.S.P., bbl.	lb.	.57 -	.65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 -	...
Benzyl chloride, tech., drums	lb.	.30 -	..35
Beta-naphthol, tech., bbl.....	lb.	.22 -	.23
Beta-naphthylamine, tech . .	lb.	.80 -	.90
Cresol, U.S P., drums. ..	lb.	.25 -	.29
Ortho-cresol, drums	lb.	.28 -	.30
Cresylic acid, 97%, resale, drums	gal.	1.15 -	1.20
95-97%, drums, resale... .	gal.	1.10 -	....
Dichlorbenzene, drums......	lb.	.07 -	.09
Diethylaniline, drums...... .	lb.	.50 -	.60
Dimethylaniline, drums.....	lb.	.42 -	.43
Dinitrobenzene, bbl,...	lb.	.19 -	.20
Dinitroclorbenzenee bbl.....	lb.	.22 -	.23
Dinitronaphthalen, bbl....	lb.	.30 -	.32
Dinitrophenol, bbl....	lb.	.35 -	.40
Dinitrotoluene, bbl..........	lb.	.20 -	.22
Dip oil, 25%, drums.........	gal.	.25 -	.30
Diphenylamine, bbl.........	lb.	.50 -	.52
H-acid, bbl.................	lb.	.80 -	.85
Meta-phenylenediamine, bbl.	lb.	1.00 -	1.05
Michlers ketone, bbl.	lb.	3.00 -	3.50
Monochlorbenzene, drums...	lb.	.08 -	.10
Monoethylaniline, drums....	lb.	.95 -	1.10
Naphthalene, flake, bbl......	lb.	.08½-	.09
Naphthalene, balls, bbl.......	lb.	.09½-	.10
Naphthionate of soda, bbl....	lb.	.58 -	.65
Naphthionic acid, crude, bbl.	lb.	.55	.60
Nitrobenzene, drums........	lb.	.10	.12
Nitro-naphthalene, bbl......	lb.	.30 -	.35
Nitro-toluene, drums........	lb.	.15 -	.17
N-W acid, bbl..............	lb.	1.25 -	1.30
Ortho-amidophenol, kegs....	lb.	2.30 -	2.35
Ortho-dichlorbenzene, drums	lb.	.17 -	.20
Ortho-nitrophenol, bbl.... ..	lb.	.90 -	.92
Ortho-nitrotoluene, drums...	lb.	.10 -	.12
Ortho-toluidine, bbl....... .	lb.	.14 -	.15
Para-amidophenol, base, kegs	lb.	1.20 -	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 -	1.35
Para-dichlorbenzene, bbl.....	lb.	.17 -	.20
Paranitroaniline, bbl...	lb.	.72 -	.75
Para-nitrotoluene, bbl.......	lb.	.60 -	.65
Para-phenylenediamine, bbl.	lb.	1.45 -	1.50
Para-toluidine, bbl	lb.	.95 -	.98
Phthalic anhydride, bbl......	lb.	.35 -	.38
Phenol, U.S.P., drums.......	lb.	.45 -	.50
Picric acid, bbl.............	lb.	.20 -	.22
Pyridine, dom., drums.......	gal.	nominal	

Pyridine, imp., drums	gal.	$2.50 -	$2 75
Resorcinol, tech., kegs	lb.	1 40 -	1 50
Resorcinol, pure, kegs	lb.	2 00 -	2.25
R-salt, bbl.	lb.	.55 -	.60
Salicylic acid, tech., bbl.	lb.	37 -	42
Salicylic acid, U.S.P, bbl.	lb.	.40 -	.45
Solvent naphtha, water-white, drums	gal.	.27 -	.32
Crude, drums	gal.	.24 -	
Sulphanilic acid, crude, bbl.	lb.	.18 -	20
Thiocarbanilide, kegs	lb.	35 -	.38
Toluidine, kegs	lb.	1.20 -	1 30
Toluidine, mixed, kegs	lb.	30 -	.35
Toluene, tank cars	gal.	.30 -	35
Toluene, drums	gal.	.35 -	.40
Xylidines drums	lb.	.47 -	49
Xylene, pure, drums.	gal.	.75 -	1.00
Xylene, com., drums	gal.	37 -	......
Xylene, com., tanks	gal.	.32 -	......

Naval Stores

Rosin B-D, bbl	280 lb	$5 90 -	
Rosin E-I, bbl.	280 lb.	6 00 -	
Rosin K-N, bbl.	280 lb.	6 20 -	
Rosin W G-W.W., bbl.	280 lb	6 50 -	7.50

Pine tar, ref, thin, bbl	gal.	-	.25
Pinewood creosote, ref, bbl	gal	-	.52

Animal Oils and Fats

Degras, bbl	lb.	$0 03½	$0 04½
Grease, yellow, bbl	lb.	06¾ -	07
Lard oil, Extra No 1, bbl	gal.	90 -	92
Neatsfoot oil 20 deg bbl.	gal	1 30 -	
No 1, bbl	gal	92 -	94
Oleo Stearine		09 -	
Red oil, distilled, d p bbl	lb	10¼	10¾
Saponified, bbl	lb	10¼	10¾
Tallow, extra, loose	lb	07¾ -	
Tallow oil, acidless, bbl	gal	94 -	96

Vegetable Oils

Castor oil, No 3, bbl	lb	$0 14 -	.
Castor oil, No 1, bbl.	lb	14½ -	...
Chinawood oil, bbl	lb	26 -	28
Coconut oil, Ceylon, bbl.	lb.	09½ -	
Ceylon, tanks, N Y	lb	08¾	
Coconut oil, Cochin, bbl.	lb.	09¾ -	10
Corn oil, crude, bbl	lb.	12¼ -	..
Crude, tanks, (f o b mill)	lb	09½	
Cottonseed oil, crude (f o b. mill), tanks	lb	09¾ -	
Summer yellow, bbl.	lb	12¼ -	
Winter yellow, bbl	lb	13 -	13¾
Linseed oil, raw, car lots, bbl	gal	1 12 -	
Raw, tank cars (dom)	gal	1 07 -	..
Boiled, cars, bbl (dom.)	gal	1 14 -	...
Olive oil, denatured, bbl.	gal	1 10 -	
Sulphur, (foots) bbl	lb	08¾	09¼
Palm, Lagos, casks.	lb	07¼ -	07½
Niger, casks	lb	07 -	07¼
Palm kernel, bbl	lb	08½ -	08¾
Peanut oil, crude, tanks (mill)	lb	13 -	13¼
Peanut oil, refined, bbl	lb.	.16½ -	..
Perilla, bbl	lb	16 -	16¼
Rapeseed oil, refined, bbl	gal	83 -	.84
Rapeseed oil, blown, bbl	gal	.88 -	.89
Sesame, bbl	lb	11¾ -	12
Soya bean (Manchurian), bbl.	lb	.12¾ -	13
Tank, f o b Pacific coast.	lb	.10¼ -	10⅜
Tank, (f o.b. N Y.)	lb	.10¼ -	.10½

Fish Oils

Cod, Newfoundland, bbl	gal.	$0 70 -	$0 72
Menhaden, light pressed, bbl.	gal.	76 -	
White bleached, bbl.	gal.	78 -	
Blown, bbl	gal.	82 -	
Crude, tanks (f o b factory)	gal.	.50 -	
Whale No. 1 crude, tanks, coast	lb	-	
Winter, natural, bbl	gal	76 -	.78
Winter, bleached bbl.	gal	.79 -	.80

Oil Cake and Meal

Coconut cake, bags	ton	$30 00 -	$31 00
Copra, sun dried, bags, (c i f)	lb	05 -	
Sun dried Pacific coast	lb.	04¾ -	
Cottonseed meal, f o b. mills	ton	38 00 -	
Linseed cake, bags	ton	33 00 -	34 00
Linseed meal, bags	ton	35 00 -	36.00

Dye & Tanning Materials

Albumen, blood, bbl	lb	$0 45 -	$0 50
Albumen, egg, tech, kegs	lb	.90 -	95
Cochineal, bags	lb	.33 -	35
Cutch, Borneo, bales.	lb.	.04¾ -	05
Cutch, Rangoon, bales	lb	13 -	13½
Dextrine, corn, bags.	100 lb	3 69 -	4 01
Dextrine gum, bags.	100 lb	3 99 -	4 09
Divi-divi, bags.	ton	38 00 -	39 00
Fustic, sticks	ton	30 00 -	35.00
Fustic, chips, bags	lb	.04 -	.05
Logwood, sticks	ton	26 00 -	30.00
Logwood, chips, bags.	lb.	.02½ -	.03½
Sumac, leaves, Sicily, bags	ton	70.00 -	72.00
Sumac, ground, bags	ton	$65 00 -	$67 00
Sumac, domestic, bags.	ton	40.00 -	42 00
Starch, corn, bags	100 lb	2.97 -	3 07
Tapioca flour, bags.	lb	06 -	.06¼

Extracts

Archil, conc, bbl.	lb.	$0.17 -	$0.18
Chestnut, 25% tannin, tanks.	lb	02 -	.03
Divi-divi, 25% tannin, bbl	lb.	.04 -	.05
Fustic, crystals, bbl	lb	.20 -	.22
Fustic, liquid, 42°, bbl	lb	08 -	09
Gambier, liq, 25% tannin, bbl	lb	.08 -	.09
Hematine crys, bbl	lb	.14 -	18
Hemlock, 25% tannin, bbl.	lb	.04 -	.05
Hypernic, solid, drums	lb	.24 -	26
Hypernic, liquid, 51°, bbl	lb	.10 -	12
Logwood, crys, bbl	lb	18 -	.20
Logwood, liq, 51°, bbl.	lb.	.09 -	.10
Quebracho, solid, 65% tannin, bbl	lb.	.04½ -	.05
Sumac, dom., 51°, bbl	lb.	.06½ -	.07

Dry Colors

Blacks-Carbongas, bags, f o b. works	lb	$0 20 -	$0 24
Lampblack, bbl	lb	12 -	40
Mineral, bulk	ton	35 00 -	45 00
Blues Bronze, bbl	lb	.55 -	60
Prussian, bbl	lb	.55 -	60
Ultramarine, bbl	lb	.08 -	35
Browns, Sienna, Ital, bbl	lb	.06 -	.14
Sienna, Domestic, bbl	lb	.03½ -	04
Umber, Turkey, bbl	lb	.04 -	.04½
Greens-Chrome, C P Light, bbl	lb.	32 -	34
Chrome, commercial, bbl	lb	12 -	12½
Paris, bulk	lb	30 -	35
Reds, Carmine No 40, tins	lb	4 50 -	4 70
Oxide red, casks	lb	.10 -	14
Para toner, kegs	lb	1.00 -	1 10
Vermilion, English, bbl	lb.	1.30 -	1 32
Yellow, Chrome, C P bbls	lb.	.20 -	.21
Ocher, French, casks.	lb.	.02½ -	.03

Waxes

Bayberry, bbl	lb.	$0 35 -	$0.36
Beeswax, crude, bags	lb.	20 -	.21
Beeswax, refined, light, bags	lb	32 -	34
Beeswax, pure white, cases	lb.	40 -	41
Candelilla, bags	lb	21 -	.22
Carnauba, No 1, bags	lb.	42 -	43
No 2, North Country, bags	lb	23 -	.23½
No 3, North Country, bags	lb.	18½ -	19
Japan, cases	lb.	16¼ -	16½
Montan, crude, bags	lb.	.04¼ -	04½
Paraffine, crude, match, 105-110 m p	lb.	.04 -	.04¼
Crude, scale 124-126 m p., bags	lb.	.02¾ -	.03
Ref, 118-120 m p, bags.	lb.	03 -	03⅛
Ref, 125 m p., bags	lb.	.03½ -	03⅝
Ref, 128-130 m p, bags	lb.	.03¾ -	04
Ref, 133-135 m p, bags	lb.	.04½ -	04¾
Ref, 135-137 m p, bags	lb	.05 -	05¼
Stearic acid, sgle pressed, bags	lb.	13 -	.13¼
Double pressed, bags.	lb	.13½ -	13¾
Triple pressed, bags	lb	.15 -	.15¼

Fertilizers

Ammonium sulphate, bulk, f o b works	100 lb	$3 25 -	$3 30
F.a.s double bags.	100 lb	3 85 -	3 90
Blood, dried, bulk	unit	4 00 -	
Bone, raw, 3 and 50, ground	ton	27 00	30 00
Fish scrap, dom, dried, wks	unit	3 75	
Nitrate of soda, bags	100 lb.	2 52½ -	2 57½
Tankage, high grade, f.o.b. Chicago	unit	3.35 -	3 45
Phosphate rock, f o b mines, Florida pebble, 68-72%	ton	$4 00 -	$4 50
Tennessee, 78-80%	ton	8 00 -	8 25
Potassium muriate, 80%, bags	ton	34 55 -	
Potassium sulphate, bags basis 90%	ton	43 67 -	...
Double manure salt	ton	25 72 —	
Kainit	ton	7 22 —	....

Crude Rubber

Para—Upriver fine.	lb.	$0 28¼ -	..
Upriver coarse	lb.	.25 -	.....
Upriver caucho ball.	lb.	.26 -	.....
Plantation First latex crepe	lb.	.29 -	
Ribbed smoked sheets	lb.	.29 -	....
Brown crepe, thin, clean	lb.	27½ -	...
Amber crepe No 1	lb.	.28½ -	.....

Gums

Copal, Congo, amber, bags.	lb.	$0.12 -	$0.13
East Indian, bold, bags	lb.	.23 -	.23½
Manila, pale, bags	lb.	.20 -	.20½
Pontinak, No 1 bags	lb.	.20 -	.20½
Damar, Batavia, cases	lb.	.28 -	.29
Singapore, No 1, cases	lb.	.34 -	35
Singapore, No 2, cases	lb.	.22 -	23
Kauri, No 1, cases	lb.	.65 -	67
Ordinary chips, cases	lb	.20 -	22
Manjak, Barbados, bags	lb.	.09 -	.09½

Shellac

Shellac, orange fine, bags	lb.	$0 62 -	$0 63
Orange superfine, bags.	lb.	.64 -	.65
A. C garnet, bags.	lb.	nominal	
Bleached, bonedry	lb.	.71 -	72
Bleached, fresh	lb.	.59 -	60
T. N., bags	lb.	.58 -	.59

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$500 00 -	....
Asbestos, shingle, f.o.b, Quebec	sh. ton	$65.00 -	$85.00
Asbestos, cement, f.o.b, Quebec	sh. ton	20.00 -	25 00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 -	20 00
Barytes, grd, off-color, f o b. mills bulk.	net ton	13.00 -	15 00
Barytes, floated, f.o.b. St. Louis, bbl	net ton	28.00 -	
Barytes, crude f.o b. mines, bulk	net ton	10.00 -	11 00
Casein, bbl, tech.	lb.	.18½ -	20
China clay (kaolin) crude, f.o.b Ga	net ton	7.00 -	9 00
Washed, f o b Ga.	net ton	8 00 -	9 00
Powd., f.o b Ga.	net ton	14 00 -	20 00
Crude f.o.b Va.	net ton	8 00 -	12.00
Ground, f.o b Va	net ton	14 00 -	20.00
Imp, lump, bulk.	net ton	15 00 -	20.00
Imp, powd.	net ton	45 00 -	50.00
Feldspar, No 1 pottery	long ton	6 00 -	7.00
No 2 pottery	long ton	4 00 -	5 50
No. 1 soap	long ton	7.00 -	7 50
No. 1 Canadian, f.o.b. mill	long ton	20.00 -	22 00
Graphite, Ceylon, lump, first quality, bbl	lb.	.06½ -	
Ceylon, chip, bbl.	lb.	05½ -	
High grade amorphous crude	ton	15.00 -	35 00
Gum arabic, amber, sorts, bags	lb	.14½ -	15
Gum tragacanth, sorts, bags	lb.	.48 -	56
No 1, bags	lb.	1.50 -	1 60
Kieselguhr, f o b Cal.	ton	40 00 -	42 00
F o b N.Y.	ton	50 00 -	55 00
Magnesite, crude, f.o b Cal.	ton	14 00 -	15.00
Pumice stone, imp, casks	lb	.03 -	.05½
Dom, lump, bbl	lb.	.05 -	.05½
Dom, ground, bbl	lb.	.06 -	.07
Silica, glass sand, f.o b Ind	ton	2 00 -	2 50
Silica, sand blast, f o b Ind.	ton	2 50	5 00
Silica, amorphous, 250-mesh, f o b Ill	ton	17 00 -	17 50
Silica, bldg sand, f o b Pa	ton	2 00 -	2 75
Soapstone, coarse, f.o.b. Vt., bags	ton	7 00 -	8 00
Talc, 200 mesh, f.o b., Vt, bags	ton	6.50 -	9.00
Talc, 200 mesh, f o.b. Ga., bags	ton	7.00 -	9 00
Talc, 200 mesh, f o b Los Angeles, bags.	ton	16.00 -	20.00

Mineral Oils

Crude, at Wells

Brass, heavy	6.50@6.75
Brass, light	5.75@6.00
No. 1 yellow brass turnings	6.75@.700
Zinc	3.75@4.25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	\$3.29	\$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

Alabama

BIRMINGHAM—The Standard Sanitary Mfg Co, Bessemer Bldg., Pittsburgh, Pa., manufacturer of sanitary enameled iron products, has acquired property at 5th Ave and 22nd St, Birmingham, as a site for a new branch plant estimated to cost about \$100,000. Plans will be prepared at once.

PELHAM—The Superior Lime & Hydrate Co, Inc, has commenced the construction of a new hydrate lime-manufacturing plant with capacity of about 500 bbl per day, estimated to cost close to \$100,000 with machinery. A list of equipment to be installed is being arranged. H. C. Bridgewater is secretary and manager.

Arkansas

CAMDEN—The Morris Oil Co, recently organized by Harry Morris and associates, has concluded negotiations with the local Chamber of Commerce for a site for a new oil-refining plant, to have a capacity for handling 3,000 bbl. of crude petroleum per day. It is estimated to cost about \$350,000, including machinery.

California

GLENDALE—The California Tylite Co, Inc, has work in progress on the first unit of a new plant near the junction of San Fernando Rd and Vine St., to be equipped for the manufacture of concrete tile products under a special process. It will have an initial daily output of 30,000 tiles. Frank H. Boettcher is president; and Charles H. Davies, vice president and general manager.

LOS ANGELES—The White Star Oil Co. has acquired property at Wilmington, Los Angeles Harbor, and plans for the construction of a new oil refinery to cost close to \$1,000,000 with machinery. A gasoline refinery will also be installed. The company is operating oil properties at Santa Fe Springs, Cal.

LOS ANGELES—The Amargosa Talc Co., 224 Santa Fe Ave., has plans in preparation for the erection of a 1-story addition to its mill, 45x100 ft. Additional equipment will be installed.

Connecticut

SOUTHBURY—The Star Oil Co., Danbury, Conn., is planning for the construction of a new oil storage and distributing plant on local site, estimated to cost in excess of \$75,000, with equipment.

Florida

BLOUNTSTOWN—The Florida Orchard & Packing Co., Thomasville, Ga., has tentative plans under consideration for the erection of a new plant for the manufacture of fertilizer products at its properties near Blountstown. W. H. Baxley, Blountstown, is president and general manager.

CANAL POINT—The Florida Sugar & Food Products Co, Lake Worth, Fla., has plans under way for extensions and improvements in its local sugar mill and properties, estimated to cost \$350,000, including equipment. F. E. Bryant is head.

MIAMI—The Southern Alpha Tile Co. has preliminary plans under consideration for the erection of a new plant on local site for the manufacture of tile products, estimated to cost in excess of \$50,000 with equipment. Allan J. Reynolds is president.

Illinois

GENESEO—The Tri-City Oil Co., 825 1st Ave., Rock Island, Ill., has tentative plans under consideration for the construction of a new oil storage and distributing plant on local site. A similar plant will also be erected at Erie, Ill. A list of equipment to be installed will be arranged at an early date. D. N. Johnson is president.

Iowa

DAVENPORT—The Linwood Stone & Cement Co, Kahl Bldg, has preliminary plans under way for the construction of a new cement-manufacturing plant to cost close to \$200,000, including equipment. J. E. Schroeder is secretary.

Kansas

ARKANSAS CITY—The Roxana Petroleum Corp, St Louis, Mo., will construct by day labor its proposed new oil-refining plant on property recently acquired. It will cost \$400,000, including machinery. Sub-contracts will be let for equipment at once. E. R. Moore is construction manager in charge.

HUTCHINSON—The State Board of Administration has completed plans for the construction of a 1-story addition to its clay products manufacturing plant, 75x120 ft, estimated to cost \$20,000, exclusive of equipment. C. M. Rutledge, State Capitol Bldg., Topeka, is state architect.

Louisiana

MONROE—The North American Carbon Co, Shreveport, recently organized with a capital of \$200,000, has preliminary plans under consideration for the construction of a new plant in the vicinity of Monroe for the manufacture of carbon black. It is estimated to cost \$80,000. C. W. Brown is president, and J. S. McCullough, vice-president.

Maryland

NORTH EAST—The North East Porcelain Co has perfected plans for immediate operations at its new local plant, and will develop maximum capacity at an early date. The company was recently organized.

Massachusetts

LEOMINSTER—Fire, May 23, destroyed a portion of the celluloid and composition goods plant of the Standard Comb Co., with loss estimated at \$25,000. It is planned to rebuild.

EAST WALPOLE—Bird & Son, Inc, manufacturer of prepared roofing products, has work nearing completion on a new plant addition, and plans to install equipment at an early date. It will cost in excess of \$175,000.

Michigan

LANSING—The Dudley Paper Co., 740 East Shiawassee St., has plans prepared for extensions and improvements in its plant, including the installation of additional equipment, estimated to cost about \$45,000. W. C. Dudley heads the company.

LUDINGTON—The Michigan Oil Development Co, recently organized with a capital of \$500,000, is perfecting plans for the development of oil properties in the vicinity of Ludington and Manistee, and the construction of a new plant in this section. A stock issue of \$100,000 has been arranged, the entire proceeds to be used for equipment and operations.

Mississippi

MERIDIAN—The Meridian Fiber Co. has completed plans and will commence the erection of an addition to its plant to cost about \$40,000. It is purposed to install additional equipment to double, approximately, the present capacity.

New Jersey

GARFIELD—The Johnson Products Co., 138 Paris St., Newark, manufacturer of cellulose products, etc., has acquired the plant of the Newark Rubber Co., at Garfield, comprising a 1-story structure with about 20,000 sq.ft. of floor space. The new owner will make improvements in the factory and plans to occupy at an early date. Charles

Johnson is president; and H. C. Johnson, vice-president and treasurer.

NORTH MILLVILLE—Frederick & Dommock, Inc., has commenced the construction of a new local plant to be equipped for the manufacture of fine glass products, including vials, etc.

NUTLEY—The Texdel Chemical Co., 391 Claremont Ave., Jersey City, has leased a factory fronting on the Passaic River, Nutley, aggregating 12,000 sq.ft., and will use the structure for a new plant. Immediate possession will be taken and equipment installed.

JERSEY CITY—The Stratford Oakum Co., Cornelison Ave., has commissioned Dodge & Morrison, 160 Pearl St., New York, N. Y., architects, to prepare plans for extensions and improvements in its 1- and 2-story plant, to provide for increase in capacity.

New York

PORT HENRY—Witherbee, Sherman & Co., 2 Rector St., New York, operating local blast furnaces, plan for the immediate rebuilding of its ore-separating plant at Witherbee, near Port Henry, destroyed by fire, May 18, with loss estimated at $300,000, including crushing, separating and other machinery. The reconstruction is estimated to cost approximately the amount of the loss.

NEW YORK—The United States Steel Corp., 71 Broadway, New York, has acquired fluorspar properties in Crittenden County, Ky., and contemplates the installation of a complete mining plant and commercial reduction works.

NEW YORK—The Publicker Commercial Alcohol Co., Water and Snyder Sts., Philadelphia, Pa., has purchased the 6-story building at 133 Washington St., and will occupy the structure for a branch works.

Ohio

LIMA—The Radiant Oil Co., recently organized with a capital of $1,000,000, has preliminary plans under way for the erection of a new plant on local site for the manufacture of lubricating oils. The company has a 3-acre tract, and will also construct a laboratory and preliminary compounding mill, the initial plant units will cost approximately $250,000, with machinery. At a later date it is purposed to construct a gasoline-refining plant, adjoining the present structures. E. E. Bessire is vice-president and general manager.

EAST AKRON—The Rote Leather Products Co., Doyle Block, Akron, has negotiations nearing completion for the purchase of the plant of the Phoenix Rubber Co., inactive for a number of months past, for a consideration said to be $150,000. The Rote company will remodel and improve the factory, and install equipment for the manufacture of leather substitute products.

CLEVELAND—The Standard Oil Co. has preliminary plans under consideration for the construction of a new storage and distributing plant on 3-acre tract of land on the Berea Rd., near Fischer Rd., recently acquired for a consideration of $21,000. It is estimated to cost in excess of $75,000, with equipment.

Pennsylvania

PHILADELPHIA—The R. E. Tongue & Brothers Co., Amber and Allegheny Sts., manufacturer of glass products, has work in progress on a new plant addition to cost about $60,000, and plans to install equipment at an early date.

LEWISTON—The Pennsylvania Wire Glass Co., Pennsylvania Bldg., is perfecting plans for the construction of the initial unit of its proposed new plant on property recently acquired at Lewiston, estimated to cost about $80,000, with equipment. Other units will be built later. Frank L. Martin is head.

PHILADELPHIA—The Pennsylvania Salt Mfg. Co., Widener Bldg., has filed plans for a 1-story extension at its plant at Porter and Delaware Sts.

NORTHAMPTON—The Atlas Portland Cement Co. has negotiations nearing consummation for the purchase of the plant of the Western States Portland Cement Co., Independence, Kan., and plans to take over the mill at an early date. Extensions and improvements will be made, including the installation of additional equipment.

UNIVERSAL—The Universal Portland Cement Co. has purchased a tract of 230 acres of land heretofore held by the Carnegie Steel Co., including its plant site and adjoining property, for a consideration said to be in excess of $2,000,000, and will utilize for general operations and expansion.

Texas

BEAUMONT—The Atlantic Refining Co., 3144 Passyunk Ave., Philadelphia, has commenced preliminary work for the construction of its proposed local oil-refining plant, estimated to cost in excess of $300,000, and purposes to inaugurate building erection at an early date.

DALLAS—The Camel Chemical Co., Portland, Ore., C. W. Hall, president, has organized the Camel Chemical Co. of Texas, as a subsidiary company, to operate a local plant. One of the former buildings of the government in the Love Aviation Field, near Dallas, has been acquired and will be remodeled and improved for an initial plant, to specialize in the manufacture of a chemical solution for battery service. Alexander D. Hudson is head of the subsidiary company.

PARIS—The Blossom Cotton Oil Co. has abandoned plans for the proposed rebuilding of the portion of its local mill destroyed by fire a number of months ago, and it is purposed to dissolve the company.

TEXAS CITY—The Texas Sugar Refining Co. has work in progress on its proposed local refining plant, and plans to have the initial buildings ready for the machinery installation at an early date. The new refinery will cost in excess of $300,000. E. T. Thomas, engineer for the company, is in charge.

New Companies

LEBANNON CHEMICAL CO., Pawtucket, R. I., chemical products; $10,000. Incorporators: Eugene X. Murphy, James Hand and Edward J. Duffy, 47 Kepler St., Pawtucket.

INTER CONTINENTAL TIRE & RUBBER CO., Indianapolis, Ind., tires and rubber products; 200,000 shares of stock, no par value. Incorporators: J. D. Wiggings, S. T. Davis and Herbert W. Lantz, all of Indianapolis.

LINDEN CHEMICAL PRODUCTS CO., New York, N. Y., chemicals and chemical byproducts; $50,000. Incorporators: M. and J. M. Marshall. Representative: E. B. Schulkind, 2 Rector St., New York.

EAST TENNESSEE CHEMICAL CO., Etowah, Tenn., chemicals and chemical byproducts; $100,000. Incorporators: W. H. Chancey, Paul H. Snapp and F. T. Purdue, all of Etowah.

HILLCREST SANITARY SPECIALTY MFG. CO., Trenton, N. J., sanitary pottery products; $50,000. Incorporators: Herman A. Jangch, Martin Boller and Frank Schuh, Homan and Hilton Sts., Trenton. The last noted is representative.

PAINT PIGMENT CO. OF AMERICA, INC., Wilmington, Del., paint pigments, etc.; $150,000. Representative: United States Corporation Co., Dover, Del.

SOFT PHOSPHATE FERTILIZER CO., Tampa, Fla., fertilizer products, organized. William G. Brooks, president, and Samuel Borchardt, secretary, both of Tampa.

BARBER TANNING CO., North Adams, Mass., operate a leather tannery; $250,000. Oliver Hall is president, and George E. Cox, North Adams, treasurer and representative.

HILL CHEMICAL CO., Wilmington, Del., chemicals and chemical byproducts; $1,000,000. Representative: Corporation Service Co., Equitable Bldg., Wilmington.

PARA CORP., Belleville, N. J., chemicals and chemical byproducts; $20,000. Incorporators: Walter H. and J. W. Zillessen and Edward G. Meyers, 372 Main St., Belleville. The last noted is representative.

REVELLE OIL CO., Bristow, Okla.; petroleum products; $100,000. Incorporators: E. H. Rollestone, Bristow, C. E. Strouvelle and C. P. Davis, both of Tulsa, Okla.

METASCALE PROCESS CO., Detroit, Mich., metal processing for scale removal; $50,000. Incorporators: Oscar M. Howard, Martin E. Ball and Joseph A. Hammer, 4301 Allendale St., Detroit. The last noted is representative.

CONTINENTAL CHEMICAL CO., Lakewood, O.; chemicals and chemical byproducts; $10,000. Incorporators: Harvey E. Miller and William H. Chapman, both of Lakewood.

WATERPROOFING, INC., Indianapolis, Ind.; waterproofing compounds, etc.; $100,000. Incorporators: James A. Walsh, Frank K. Bull and Lee R. Garber, all of Indianapolis.

C. H. A. SCHMITT CO., Boston, Mass.; chemicals and chemical byproducts; 400 shares of stock, no par values. Charles A. Schmitt, president; and Philip J. Kraft, Boston, treasurer.

INSULATING PRODUCTS CO., 412 North Western Ave., Chicago, Ill.; compounds; $40,000. Incorporators: Louis Weber, William J. Greer and Fred Ellzer.

MARR OIL CORP., 101 East Fayette St., Baltimore, Md.; refined petroleum products; 500,000 shares of stock, no par value. Incorporators: John J. Hopkins, Carl W. Painter and J. Donald Robb.

PROTECTION PAINT & PRODUCTS CORP., 8 South Dearborn St., Chicago, Ill.; paints, varnishes, oils, etc.; $25,000. Incorporators: Mortimer A. Sherick, A. B. Sherick, and Henry Rutz.

EX-OIL CHEMICAL PRODUCTS CO., Jersey City, N. J.; chemicals and chemical byproducts; $100,000. Incorporators: Francis I. Golden, Alexander Mannix and James H. Sharkey, 225 Claremont Ave., Jersey City. The last noted is representative.

FARMASTIC CO., Haverford, Pa.; paints, varnishes, etc.; $250,000. Incorporators: Frank A. Cabeen, Jr., Haverford; George G. Meade, Ambler, Pa.; and W. F. Diener, Collingswood, N. J. Representative: United States Corporation Co., Pennsylvania Bldg., Philadelphia, Pa.

CONSOLIDATED BOLL WEEVIL & INSECT DESTROYER CO., Blanchard, Okla.; chemical compounds; $25,000. Incorporators: John A. Stephenson, D. C. Morgan and T. C. Laws, all of Blanchard.

DALCO LUBRICANTS, INC., Wilmington, Del., oils and greases; $120,000. Representative: Corporation Service Co., Equitable Bldg., Wilmington.

FINDLAY-EAGLE OIL CO., Findlay, O.; oil products; $25,000. Incorporators: W. E. Stephenson and M. H. Shaffer, both of Findlay.

LASTIK PRODUCTS CO., Beaver, Pa., cements, paints, etc., now being organized, application for a state charter will be made June 6. Incorporators: E. A. Holland, J. deS. Freund and S. B. Myers. Representative: Hice, Morrison, May & Bradshaw, Beaver.

Industrial Notes

THE WHEELING STEEL PRODUCTS CO. (sales company for the La Belle Iron Works, Whitaker-Glessner Co. and Wheeling Steel & Iron Co.) discontinued May 1, and the Wheeling Steel Corp., from that date, has handled all sales. The Wheeling Steel Corp. will assume all existing sales obligations of the Wheeling Steel Products Co., Wheeling, W. Va., and of the three above named companies. This action will not affect the personnel of the sales division, which will remain unchanged at Wheeling and at district sales offices.

THE CONVEYORS CORP. OF AMERICA, Chicago, Ill., announces the appointment of the Pittsburgh Machine Products Co., Oliver Bldg., Pittsburgh, Pa., as district representative.

Since May 15 the firm of PETREE & DORR has occupied separate office from the Dorr Co. in the Munson Bldg., 67 Wall St., New York City, and has enlarged its staff. P. M. McHugh, until now vice-president and manager of sales of equipment for the Dorr Co., will become president and general manager of Petree & Dorr. C. G. Petree of Brisbane, Australia, will become vice-president and consulting engineer. J. V. N. Dorr, president of the Dorr Co., will be chairman of the board of directors. H. E. Haws, treasurer of the Dorr Co., will continue as treasurer for the present. G. C. Kaar will continue in charge of the office in Havana.

THE WEBSTER MFG. CO., Chicago, Ill., announces the appointment of Robert T. Pierce as manager of its New York sales office at 90 West St., succeeding Glen N. Porter, deceased.

Opportunities in the Foreign Trade

Parties interested in any of the following opportunities may obtain all available information from the Bureau of Foreign and Domestic Commerce at Washington or from any district office of the bureau. The number placed after the opportunity must be given for the purpose of identification.

LINSEED OIL, coconut oil and palm kernel oil, 10 to 50 tons of each, all of the best quality. Wurttemberg, Germany. Purchase.—6497.

EDIBLE OILS AND LARD. Vienna, Austria. Purchase.—6502.

VEGETABLE OILS AND LARD. Prague, Czechoslovakia. Purchase.—6517.

WINDOW GLASS AND CAUSTIC SODA. Rio Grande do Sul, Brazil. Manufacturers' agency.—6543.

VARNISHES AND PAINTS, hard aluminum. Madrid, Spain. Purchase.—6594.

How Shall We Sell Our Research?

"WHAT kind of a report shall we turn in to the board of directors? Shall it be a simple statement of results achieved in terms of dollars and cents saved? Or shall it include the results aimed at, a perspective of the work in terms of the long-time problems with incidentally some mention of the ultimate goals?" This subject was the basis of a friendly discussion among the heads of the research department in one of the large industrial corporations. The question is fundamental. It involves the very basis for research and it is imperative that those of us who are trying to "sell" that commodity to industry should clear up in our own minds the proper basis for its sale.

The confusion arises probably from the habit of looking upon research as an investment that will pay dividends. Our attitude toward research must be more flexible. Investments carry with them a connotation of regular profits, of capital once invested which keeps turning itself over. These concepts are ingrained and are not easily shaken. Therefore when we speak of research as an investment we are unfair, for we tell only a part of our story. True, it is a "laying out of money from which profit is expected," but it does not yield regular profits, nor is it a single laying out of money. It is a repeated expenditure. It is an "investment" without the earmarks familiar to the layman. Hence there is danger in referring to it in terms of profits and dividends.

It is a fact well established that research will pay for itself many times over, and in that sense it is an investment. But it is much more than an investment. It is the insurance which every company should pay to make sure that its processes and its products are not obsolescent—a condition that cannot always be revealed by the cost system. It is furthermore the eyes of the corporation through which it may look into the future. Only through research can an industry, a corporation, or an individual anticipate conditions and turn them to advantage. On the other hand, only research can create conditions that will permit life and growth in industrial competition.

Is a board of directors to be informed solely of the dollars and cents which the research department has saved during the past fiscal year and to be given no insight into the aims for which it is striving? What will be the result? A demand for dollars and cents! A necessary abandoning of long-time research, fundamental study aimed at the future, to take up pot-boilers that will show an immediate profit. Instead of studying the possible utilization of low-grade phosphate rock in the manufacture of fertilizer it would be the analysis of samples to prove that the company was right in a single shipment. In place of the fundamental properties of portland cement, the research man would have to "trouble shoot" for an irate customer.

Sell research for what it is: Not a penny saver on the present budget, but a marvelous tool that will create conditions for an industry, new methods of production, products for a waiting market. Sell it as an economic force and an economic necessity. Sell it as a program that has vision and vitality. Sell it so that every board of directors shall come to know it not as an investment but as a searchlight into the unexplored future of the corporation.

Looking to the Future Of the Paper Industries

A PERIOD of unusual prosperity has recently been enjoyed by the paper and pulp industries. If such good times could be continued and upon the same basis of production as in the past, there would be but slight ground for the speech of HUGH P. BAKER, secretary of the American Pulp and Paper Association, before the recent convention of paper mill superintendents at Springfield, Mass. Unfortunately, such may not be the case.

The time is fast coming when keen foreign competition must be met. Our Canadian neighbors give promise of outstripping us in newsprint production within 2 years. Our own forests are rapidly being depleted and the need for adopting a sound policy of reforestation becomes not only advisable but vitally necessary. Even such a step, however, will not in itself fully prepare us for holding our production and markets.

Standardization must come in mill practice. Of 129 sulphite mills operating on this continent, no two have adopted a standard, common practice. Why? Simply because the mills cannot agree among themselves which method is best. Only sound, honest, co-operative study will solve this problem. Fortunately the oil and steel industries have set excellent examples of standardization which the pulp industry might well emulate.

In addition to the development of new sources of raw material and standardization of practice, the industry has other problems to face. Sewer drains and ventilators, smoke stacks and refuse piles must be cheated of their present harvest. The statement has been made that a 200-ton mill could be completely operated on the present-day waste of the industry—and there is evidence to lead us to believe that this estimate is conservative.

To meet foreign competition successfully the industry must produce at bedrock prices. To do this it must insure itself against lack of pulpwood, it must standardize, it must discover and prevent unnecessary losses. Otherwise the day may come in the not far distant future when the foreign producers succeed in dominating the paper market of the United States.

An Introduction to the Chemical Engineering Industries

THE student at the Chemical Exposition has always been a problem. Usually he has rambled around on his own and worn out the patience of exhibitors by his persistent questioning. Nor has he been as greatly benefited by the exposition as he might have been. He has merely gathered a series of random impressions, generally inaccurate and all uncorrelated. His sense of balance has often been entirely disarranged by a loquacious salesman or a taciturn one. So much for the problem.

The Ninth Exposition, next September, will have as one of its features a course of instruction for students. Already our news pages have carried the preliminary announcement. More than a hundred applications have been received and the final attendance will doubtless be treble that number. Distinguished engineers have accepted the task of conducting the various symposiums and the students will have a rare opportunity to get a feeling of the great industries which later on will furnish them their livelihood. The generous co-operation of Columbia University in offering rooms in its dormitories for the week at a nominal charge removes the expense bugbear with which the student is usually faced. It only remains for the student to take advantage of this progressive proposal and for the exhibitors to co-operate in making this introduction to industry a significant advance in chemical engineering education.

Curious Ideas of Conservation

IN A recent issue of *Science* we learn that an unknown donor has contributed $100,000 each to Harvard and Yale universities for the purpose of conducting experiments in silviculture in New England. This is a matter of real interest, especially to the pulp and paper, wood-distillation and other of our chemical engineering industries. On every hand come warnings that we are using up our timber supply and yet despite the good work of the Forestry Service and the Forest Products Laboratory, we are curiously unscientific in our attitude toward this problem. To make silviculture economically worth while will require research and thinking, and the university is an admirable place for this study.

It is reported that on the Canadian side of the imaginary line that separates Alaska from the dominion there is a large and thriving paper and pulp industry. For the most part it is in the hands of Americans who were forced out of Alaska by the peculiar conception of conservation that seems to have as its objective that there be no development anywhere—that water capable of developing power should continue to waste itself on the rocks of its stream bed and that trees should continue to grow to maturity and then fall down to rot and ruin.

Good business requires that we begin to connect up these long-distance subjects and predicates, these causes and effects that reach out over the passing years. We have no right to rob future generations of the resources they will most need, but we should not unnecessarily penalize industry by withholding raw materials that today are being dissipated because of the *laissez-faire* attitude and neglect. A scientific program of utilizing the growth of our forests is not inconsistent with the soundest policies of conservation.

Technology and the Raw Material Monopolies

AS A NATION the United States is dependent upon foreign countries for about fifteen essential raw materials. At least half and probably two-thirds of these commodities are of vital importance to the chemical engineering industries. We are, therefore, more than ordinarily concerned with the attempt that is being made to find out just what these monopolies really mean in the world economic structure. Secretary HOOVER and his associates in the Department of Commerce should be assured of our support for their investigation, not alone in moral encouragement but, if necessary, in aggressive technical effort.

It is perhaps a war heritage that practically all of these materials are dominated by combinations of companies or governments that control production or marketing and distribution. Potash, iodine, nitrates, quinine, rubber, sisal and tanning materials are chemical engineering products subject to just such control. And, as the Secretary well puts it, there is no "Sherman law of the world" to prevent combinations against the United States. There are at least four ways to meet these raw material monopolies: (1) By similar combinations of purchasers; (2) by development of new sources of the same raw materials; (3) by development of synthetic or substitute materials; (4) by measures of economy to reduce our dependence on foreign sources.

But the immediate technical problem presenting itself to our industries is that of developing synthetic supplies or the determination of adequate substitutes for the raw materials which are now available from single sources. In the case of nitrogen, for example, the fixing of atmospheric nitrogen affords the obvious measure of relief from the burdensome phases of Chilean nitrate control. But the very serious economic question is, Will it pay? Similarly in the case of rubber the preparation of synthetic rubber is at least a possibility, although nothing like the certainty which we have in the case of nitrogen fixation. In other cases the whole situation may turn on a very small and apparently insignificant bit of technology. This is actually what is likely to result in the case of sisal.

The story of sisal is a romantic one. It has always seemed to be the only cheap fiber suitable for making binder twine that would withstand the ravages of the grasshopper. Other fibers such as manila are eaten by this insect pest, with serious results to the farmer who must handle the sheaves of grain. But now a little investigation has shown that the honorable grasshopper has no more desire for manila than for sisal. His fastidious taste is simply for the salt that is left in the manila and other twine fibers because the fibers have always been washed in salt water. Other factors of importance may develop, but it now seems that the only measure required for relief against the sisal monopoly is to arrange that the producers of manila in the Philippines use fresh water in the cleaning of their fiber, thus eliminating the salt which savors the grasshoppers' meal.

It is not likely that as simple solution will be found for the fourteen other raw materials as now is promised for the binder twine situation, but the chemical engineer has in every one of these fields a distinct opportunity. Our industries cannot afford to remain dependent upon a single foreign source. Common sense and good economics forbid that our profession should sit idly by and allow the present condition to continue.

One Aspect of The Labor Shortage

A GREAT DEAL is heard lately of the effect which the current shortage of labor has on industry. The prosperous state of business leads many industries to seek to attain maximum production. It becomes immediately evident to such that there are no new laborers available and that it is necessary to make their present supply cover their needs. In consequence we note a loud clamor that the next Congress should let down the bars to an increased immigration, and, with this, a tendency to do nothing until such Congressional action occurs.

But there is every indication at present that the immigrant quotas will not be increased. This puts it squarely up to industry to find its own solution of the difficulty. From one point of view this may be a blessing in disguise. What is being done in some plants, and it is the logical thing for all at least to consider, is the substitution of labor-saving devices and material-handling equipment for unskilled labor and then training the men thus freed for the skilled jobs that are open. Such a plant is blessed with steadier and more economical operation. Its men enjoy better jobs at better pay. And dividends result to the industry which acts instead of waiting helplessly for the government to solve its difficulties for it.

Better Tools For Industry

AN ENGINEERING FRIEND of ours, whose principal work has been along metallurgical lines, recently made an excursion into the chemical field. He tells us he was amazed by the lack of authoritative fundamental data and the very abundant fund of misinformation concerning the products in which he was interested. He writes:

> Take a very commonplace chemical, epsom salt, for example; consult any number of solubility tables and you will find almost as many sources of conflicting information. You will learn that this salt is relatively soluble, 1 to 3 in cold water and 1 to 1 in hot water, but the particular table consulted will give you no information whatsoever as to the temperatures involved. Another source discloses that 258 grams are soluble in 1,000 cc. of water at 32 deg. F. and 1,000 grams at 212 deg. F. . . . Epsom salt melts in its own water of crystallization at 200 deg. F., but none of the ordinary tables so states. . . . Should not the chemist make it his business to publish the truth? Should not the chemists as a group make it their duty to separate out the misinformation existing in many of our technical books and conspicuously label it as "Obsolete"?

It is not our purpose to defend the engineer in his criticism of the chemist nor yet to point out the fallacy of his generalizations. His criticism may or may not be well taken, but it serves to emphasize the very urgent need for the compilation and critical study of the fundamental constants of industry. It also brings out another point and one that is common experience to most of us —viz., that when we get away from the very limited field of our own specialty we are incapable of judging and appraising conflicting values for these basic data.

What is needed is co-ordinated, critical study by specialists, each competent to judge the value of the data for his particular field. It is encouraging to learn that this is exactly what is being planned in connection with the great work now under way on the preparation of the International Critical Tables of Physical and Chemical Constants.

The Landolt-Börnstein-Roth Tabellen, on which many of our technical men are now forced to rely, are notably incomplete and inadequate. In them there is no recognition of the results of much of the scientific and industrial research conducted in the United States since 1914. Nor do the tables include essential data on the many new and useful technological materials. These obvious faults are to be corrected and many new and noteworthy features are to be included in the ambitious program outlined for the present undertaking. It is impossible here even to catalog the wide range of data that will make up the 2,000 pages of tables, but the briefest inspection of the preliminary plans brings convincing proof that practically every phase of industry will be benefited by these tabulations. The project is an enormous one, requiring whole-hearted co-operation as well as prompt and substantial financial support.

As the matter now stands, about fifty industrial units have pledged approximately $40,000 and the Carnegie Corporation has given $35,000 more for the project. An additional $125,000 must be raised in order to cover the entire expense of compilation, editing and publishing. But even an expense of $200,000 is only an inconsequential fraction of the value that will be derived once industry is supplied with these better tools for investigation and progress.

Chemical Engineering In Industry

OCCASIONALLY we hear of friends of ours, chemical engineers, who are holding responsible positions in a rubber plant, a cement factory, a soap works, a packing house, a baking plant, an enameling factory and so on *ad infinitum*. If we reflect upon it at all, we begin to realize to what far fields of service the chemical engineer is being called. Yet this realization is very vague, whereas both the true comprehensiveness of the field and the striking parallelism of the work of the chemical engineer in different fields are far from being appreciated by the chemical engineers themselves.

These two thoughts underlie a series of articles on the chemical engineering of many industries. Based on field inspection of modern progressive plants by members of *Chem. & Met.'s* editorial staff, these will give a series of glimpses into the work of the chemical engineer from which can be synthesized a composite picture of chemical engineering which no single article could possibly give.

The series starts in this issue with "Chemical Engineering in the Production of Coated Fabrics"—a study of the Duratex Corporation's plant at Newark, N. J. Other articles will follow at close intervals. The effort will be sustained and the program will extend over a period of years rather than weeks or months. Each article will focus on the important chemical engineering features of the industry and plant. Gradually the understanding that the unit processes of chemical engineering underlie all of the process industries will become part of the background of the chemical engineer himself, of the industries and of the industries' leaders. Toward this end these articles are frankly aimed. We commend them to your attention.

Milton C. Whitaker

Outstanding chemical engineering executive and pioneer in the fight for the legitimate use of alcohol in industry

"ETERNAL VIGILANCE is the price of liberty" in more than one line of human endeavor, but in no industry is this so strikingly apparent as in the production and lawful distribution of industrial alcohol. Notwithstanding the federal enforcement act's avowed purpose ". . . to insure an ample supply of alcohol and to promote its use in scientific research and in the development of fuel, dye and other lawful industries," the industrial alcohol manufacturer and the industries that depend upon him for their supply of this essential raw material have been consistently harassed and persecuted. Only by a constant wide-awake fight for their rights have the chemical industries been able to oppose the ill-advised and often unjust regulations forced upon them by a fanatical administration of the enforcement act.

A step forward for the alcohol manufacturer and a victory for the legitimate consuming industries were recently achieved by the appointment of the Trade Alcohol Advisory Committee. On June 1 the announcement was made that in the future all new regulations affecting industrial alcohol will be submitted to this committee by the Treasury Department in order that blundering rules may be corrected before they actually go into effect and do damage to legitimate industry.

Another development within the past few weeks has been the discovery that hidden away in the recently-repealed Mullan-Gage enforcement act in New York State was a definition of "intoxicating liquor" which if enforced would absolutely prevent the use of alcohol in any chemical, medicinal, varnish, motor-fuel or in fact in any product requiring more than ½ per cent of alcohol in its make-up.

A striking example of the industry's successful stand against ill-advised legislation was seen a year or more ago in the opposition to the Willis-Campbell ("Volstead, Jr.") bill before Congress. It will be recalled that the industrial alcohol committee of the American Chemical Society made a valiant presentation of the chemical industry's case against the bill. This was supplemented by the important though perhaps less prominent rôle played by Dr. Milton C. Whitaker, former professor of chemical engineering at Columbia and now vice-president of the U. S. Industrial Alcohol Co. and president of the U. S. Industrial Chemical Co. His clear, forceful testimony before the Congressional committees did much to swerve the radical prohibitionists from their fixed purpose of crippling lawful chemical industries.

Dr. Whitaker has said that his business is to make alcohol and other chemicals for industry and not for illegal purposes. He is constantly blocking the efforts of bootleggers and at the same time appealing to the authorities on behalf of legitimate industries in order to enable them to do business. And this eternal vigilance is necessary, for there are always enthusiasts in Congress who believe that alcohol is useless as well as dangerous and that carbon bisulphide, for instance, would be a proper substitute for it in medicinal extracts.

Chemical Engineering In the Production of Coated Fabrics

Manufacture of Artificial Leather and Rubberized Cloth at the Plant of the Duratex Corporation Involves Interesting Application of Engineering Principles

BY SIDNEY D. KIRKPATRICK
Assistant Editor, *Chem. & Met.*

WITHIN the last 10 years more than one of the chemical engineering industries has felt the stimulating influence of the quantity-production methods of the automobile manufacturer. Many recent significant advances in the technology of rubber, special alloys and steel, and paint and varnish, can be traced directly to the demands of the industry that in 1922 supplied us with 2,500,000 motor cars and trucks. But even more intimately connected with the automobile industry is the production of pyroxylin- and rubber-coated fabrics—artificial leather for upholstery, door linings and the tops of closed cars and rubberized cloth for the side curtains and tops of touring cars.

The artificial leather industry had its beginnings in England early in the nineteenth century, but it was not until about 1850 that it may be said to have taken root in the United States. At that time, the principal use for such material was in the manufacture of carriages, the predecessor of the automobile industry, which alone in 1922 consumed 50,000,000 yd. of artificial leather.

Certain of the firms now producing pyroxylin- and rubber-coated fabrics had their origin in the leather industry, which, in brief, is the history of the Duratex Corporation, of Newark, N. J. About 20 years ago the Johnson Leather Co., of Newark, began the manufacture of split leather and for many years supplied this material to the carriage trade. About 1916, however, the demand for increasing quantities of automobile upholstery material became so insistent that this firm started to produce artificial leather, which it marketed under the name of "Duratex." A year later the firm, now known as the Duratex Corporation, began to produce rubberized fabrics, and with the broadening demand for this material expanded its rubber department until it is now able to supply approximately a tenth of the consumption of the entire country.

The chief raw material common to both the pyroxylin and rubber departments is the fabric, or gray goods, as it is termed in the industry. Depending upon special requirements, this may be duck, twill, drill, sateen, moleskin, lawn or sheeting. The gray goods first go to the dye house, where they are dyed, stretched and, in some cases, napped and felted. From the dyed goods storage, they are taken to the makeup room, where the rolls of cloth are cut according to the orders of the planning department and are sent to the appropriate department for processing. If the goods are to be rubberized, they are taken either to the calender room or rubber-spreader room, depending upon which of the two methods is to be used for applying the rubber. If the cloth is to be made into artificial leather, it passes into the pyroxylin room, where the "dope" mixture of nitrocellulose, pigment, oils and solvent is applied. The heavy rolls of cloth are transported from one building to the other by hand trucks, although in the processing rooms they are more conveniently and efficiently handled on a monorail system installed by the Louden Machinery Co. (See Fig. 5.)

As will be observed in Fig. 1, the plant is housed in two 1½-story brick buildings, 60 ft. in width and approximately 500 ft. in depth. A third series provides for material storage and power generation.

Pyroxylin Department

The preparation of the coating mixture of nitrocellulose, solvent, oils and pigment is the first step in the manufacture of artificial leather. Many of the valuable properties of the finished product depend upon the composition and care used in the making of this coating solution, which is known in the industry as "dope."

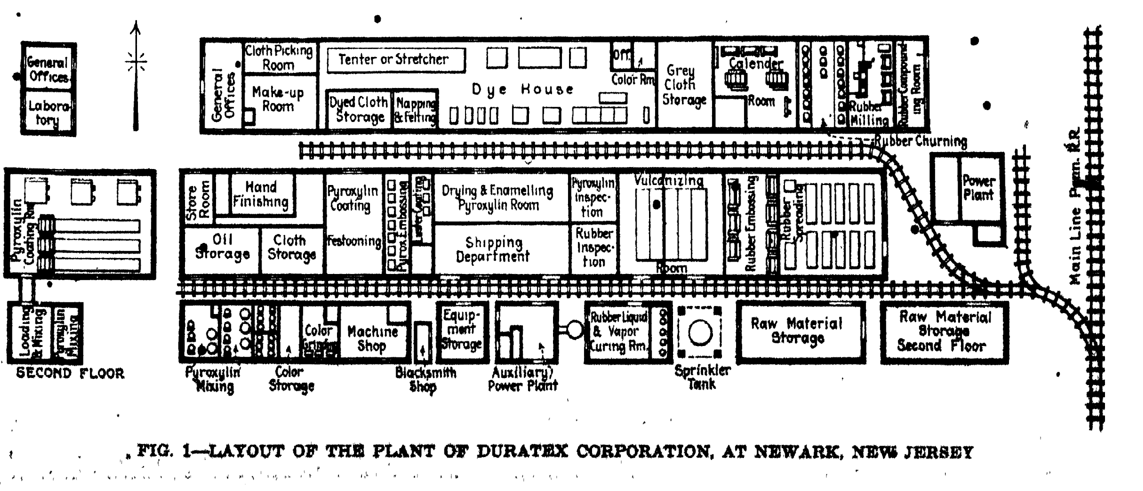

FIG. 1—LAYOUT OF THE PLANT OF DURATEX CORPORATION, AT NEWARK, NEW JERSEY

At the Duratex plant the pyroxylin is generally purchased in the form of a 12 per cent solution of nitrocellulose in a specified mixture of solvents. In general terms, this mixture consists of a diluent, a latent solvent and a true solvent. Because of its unusual solvent properties, ethyl acetate is almost universally used as the true solvent. Denatured alcohol is a common example of a latent solvent, while benzol and toluol are most often used as diluents.

Although the composition of the solvent mixture varies greatly with the coating requirements and other factors, such as atmospheric conditions, the true solvent generally represents 40 to 50 per cent of the total. Typical mixtures might be made up as follows:

	Ethyl Acetate Per Cent	Benzol Per Cent	Alcohol Per Cent
Solvent A...........	40	30	30
Solvent B...........	40	35	25

A difficulty which the artificial leather manufacturer shares with other pyroxylin industries is caused by the occasional precipitation of the nitrocellulose, resulting in what is known as a "blush" or "bloom" in the finished product. One of the reasons for this is the addition of moisture condensed from the atmosphere because of the low temperature of the evaporating solvents. In moist weather, therefore, it is necessary to add to the solvent mixture a small quantity of a higher boiling solvent, such as amyl or butyl acetate. A typical solvent mixture for use during periods of high humidity might consist of 10 per cent of amyl acetate, 30 per cent of ethyl acetate and 60 per cent of benzol.

Grinding, Mixing and Coating

The pigments mixed with the pyroxylin are all chemically inert colors—ochers, siennas, bone black, prussian and ultramarine blues, indian oxide and scarlet lakes being especially desirable. In this plant these are ground in a non-drying or semi-drying oil, such as castor oil, on three J. H. Day three-roller paint mills, one of which is shown in Fig. 2. The pigment-grinding room has a capacity of producing approximately 3,600 lb. of ground pigment in 24 hours.

Although varying, of course, with the specific gravity of the pigment and the color requirements for the finished stock, it is common practice to mix the ground pigment with the nitrocellulose solution in the proportion of two parts of pigment to three of nitrocellulose.

FIG. 2—PIGMENT GRINDING ON THREE-ROLLER MILL

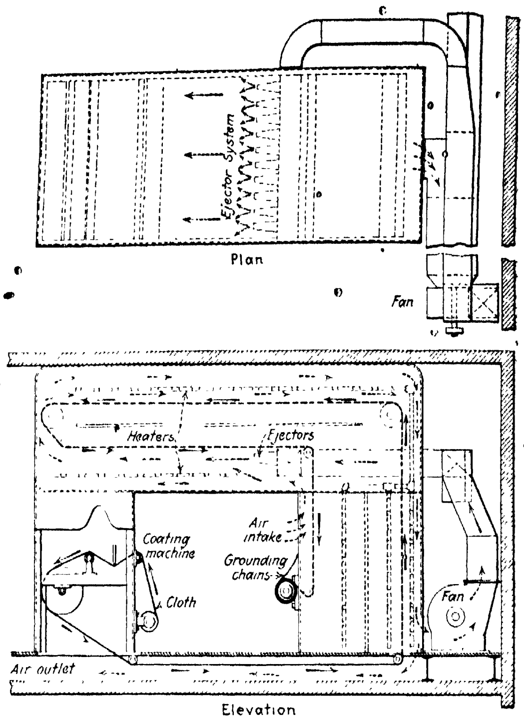

FIG. 3—PLAN AND ELEVATION OF DRYING EQUIPMENT FOR PYROXYLIN COATING MACHINES

Softening oils, such as castor, rapeseed or other non-drying or semi-drying vegetable oils, are then added to the mixture, generally in the proportion of about two parts of oil to one of nitrocellulose. This proportion, however, may be varied considerably depending on the pliability desired.

The pyroxylin mixing—that is, the incorporation of the various ingredients of the coating solution—is accomplished in large mixers made by the J. H. Day Co., of Cincinnati, and E. Ross & Son, of Brooklyn. In all, twenty-four such mixers are used, having individual capacities of 300, 500 and 800 gal. The ingredients are fed into the top of the mixers; in the case of the larger ones, from a second floor room directly above (marked "Loading and Mixing" in Fig. 1). The smaller mixers are loaded from overhead platforms to which the pigment and solution are brought by monorail and lifted by block and tackle.

It is significant that the mixers have been installed in three distinct rooms, carefully separated by fire walls. Necessary precautions are taken against the danger of ignition by static electricity. The mixers, belts and pulleys are carefully grounded and it has also been found necessary to ground the operators themselves, especially in cold, dry weather. This is done by having the men stand on zinc plates, properly grounded through the floor. The cloth is itself grounded to the coating machines by means of small brass chains that drag over the surface of the coated cloth during the final roll-up. (See Fig. 3.)

It was previously pointed out that the planning department routes the dyed cloth from the makeup room directly to the individual coating machines of the artificial leather department. Here the weight of the fabric

is ascertained and, also, by calculation, the amount of coating necessary to bring the finished product to its required weight.

The pyroxylin mixture is applied to the fabric on two types of coating machines, one of which is shown in Figs. 4 and 5. These are comparatively simple in principle, the thickness of the coat being regulated by the tension of the cloth against a knife edge over which it passes. The first and most difficult coat to apply is the anchorage coat, which is followed by the other coats necessary to give the required weight and the desired flexibility, finish and embossing surface.

As the fabric leaves the knife edge, it passes into a drying chamber, which is heated by means of steam coils. The temperature is regulated and recorded by standard recording instruments of the Foxboro and Bristol types.

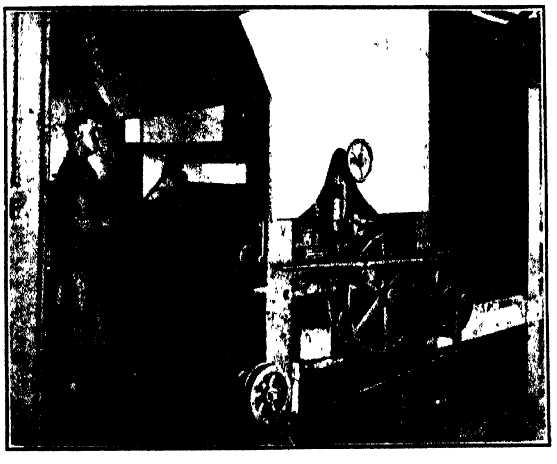
A Problem in Air Drying

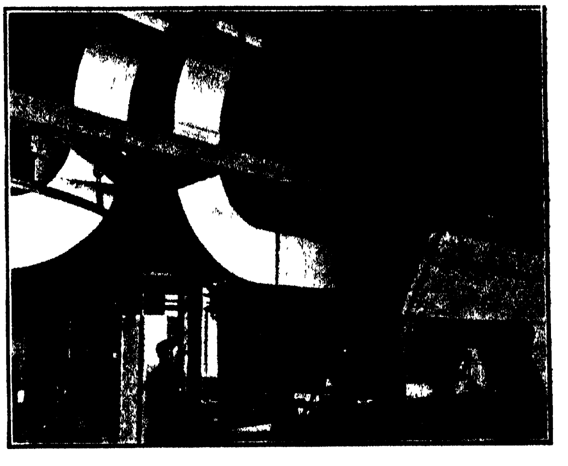
This drying equipment is an especially interesting application of air drying under rather unusual conditions. It is necessary to provide facilities for drying the base coating as rapidly as possible and, at the same time, to remove the solvent vapors effectively, in order to keep explosion and fire hazards at a minimum. The system was designed and installed by the Carrier Engineering Corporation and makes use of the ejector principle for efficient circulation of the air. As may be seen from the plan and elevation shown in Fig. 3, it is designed according to well-known counter-current principles. The air is delivered from the ejector nozzles at a velocity of approximately 1,000 ft. per minute, and passes over the driest cloth as it is on its way out of the drying chamber. In counter-direction the air then passes around the entire path covered by the cloth and is finally exhausted at an outlet directly beneath the coating head of the machine. At the base of the fan, the air current divides and a part of heated air is drawn into the fan to be recirculated directly by the ejector nozzles.

The apparatus handles about 2,500 cu.ft. of air per minute for each of the coating machines. The temperature is maintained at approximately 175 deg. F. depending upon the amount of air handled and how vigorously it is circulated. The drying chambers over the machines are connected with an exhaust system which removes a sufficient quantity of the fume-laden air, to prevent an explosive concentration. At the present time no provision is made for solvent recovery, although the drying and ventilating system is so designed that an installation might be made with a minimum of expense and inconvenience.

The second type of coating machine, known as the spool calender machine, coats at a much faster rate. The fabric from these machines is dried in a hanging room, suspended from the ceiling in festoons. The temperature in the festooning room is usually about 130 deg. F., but this too depends on the rate at which the cloth is drawn through the room. The time may be varied from 2 to 4 hours.

As the product comes from the coating machines, it has a smooth surface and looks very much like ordinary oilcloth. In order to give it the appearance of leather the coated fabric is grained or embossed under high pressure. The presses used are those of the T. W. & C. B. Sheridan Co., mechanically operated by means of a cam and triple toggle construction. On a surface 54x26 in., these presses are capable of giving a pressure of 600 tons. The embossers are of two types, a continuous press such as is shown in Fig. 6, in which the cloth is rewound automatically after each impression, and a non-continuous type, in which the leather is pulled through by hand or is rewound by the operator. The six presses in the leather embossing room have a total capacity of 30,000 to 40,000 yd. per 24 hours.





FIGS. 4 AND 5—PYROXYLIN COATING MACHINES SHOWING EXHAUSTING AND DRYING EQUIPMENT

The embossed leather receives a final coat of pyroxylin in order to give it the finish and luster desired in the finished product. This is done on coating machines somewhat similar to those already described. As will be seen in Fig. 8, these machines are provided with an ingenious exhaust system in order to remove the fumes which otherwise would diffuse throughout the room, becoming very objectionable to the workmen. The exhaust is through a duct extending along the sides of the path of the fabric and across and immediately above it, as it leaves the coating room. The vapors to be removed, being heavier than air, fall off the fabric and are drawn into the duct and through it are exhausted into the atmosphere. The quantity of air handled is simply sufficient to maintain the required suction at the duct openings.

From these machines the finished goods are drawn

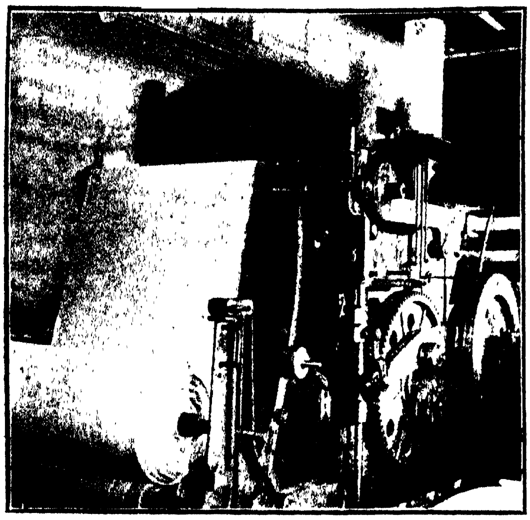


FIG. 6—LEATHER EMBOSSING PRESS SHOWING AUTOMATIC REWINDING ATTACHMENT

into another festoon drying room kept at a temperature of about 140 deg. F., from which they pass to the inspection room and shipping department.

Rubber Department

Many of the manufacturing processes in the production of rubber-coated fabrics are similar in principle to those described for artificial leather. The essential difference in the raw materials, however, and the characteristic properties of rubber itself require a very different procedure in certain steps in the manufacturing process.

The ingredients of the rubber mixes and the proportions in which they are used vary widely with the purpose for which the finished product is intended. In general, auto-top material requires the use of the following materials: para or plantation rubber (smoked sheets), reclaimed rubber, litharge, sulphur, whiting, and various softening agents, such as vulcanized oils, mineral rubber, etc. These are weighed out in charges of the proper volume to be handled in the rubber mixing machines or on the mills.

The mill room equipment consists of two Banbury internal mixers and three Wellman-Seaver-Morgan 60-in. mixing mills. The latter, which are similar to

FIG. 7—LABORATORY OF DURATEX CORPORATION

those shown in Fig. 9, are driven by a 300-hp. induction motor operating through reduction gears. Two of the mills are used for rubber mixing and the third sheets out the batches coming from the internal mixer. Directly above the rolls of each mill are safety bars electrically connected with the drive through a Cutler-Hammer magnetic clutch. In case of accident any mill can be stopped within a 6-in. travel simply by tripping this bar, thus minimizing the seriousness of the injury to the operator.

The Banbury mixer shown in Fig. 10 is unique in that it is practically automatic and accomplishes the mixing in an inclosed chamber. Essentially it consists of a trough, closed by a pneumatic ram which effectively holds the charge against the revolving blades that accomplish the actual mixing. The charge is raised on a small pneumatic elevator to a loading platform, and the batch is thrown into the feeding hopper while the machine is in operation. It is not touched then until the material is thoroughly mixed, at which time it is ejected, by means of compressed air, through a discharge gate at the bottom of the mixer. The rubber is discharged in large lumps which are worked into sheets on one of the 60-in. mills.

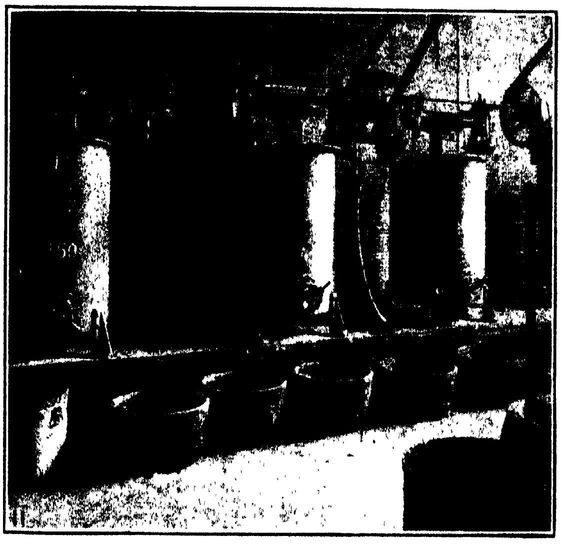
FIG. 8—LUSTER COATING ARTIFICIAL LEATHER

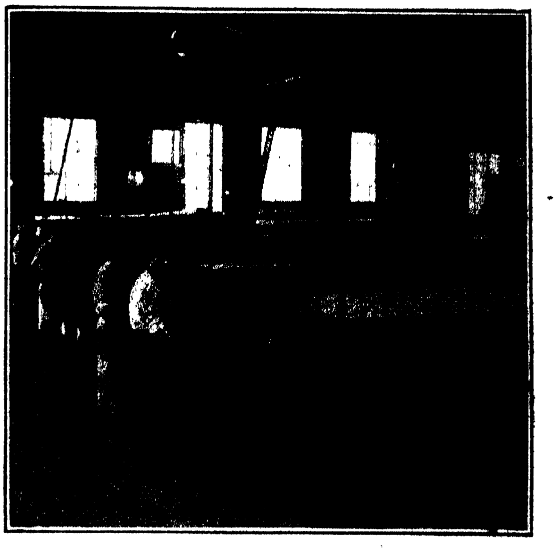
In this form the rubber is ready for the next step in the process, depending upon which of the two methods is to be used for applying it to the cloth. It may be sent to the churn room, where it is mixed with naphtha to make up a coating cement, or it may be sent to the calender room to be applied directly to the fabric.

How the Rubber Cement Is Made

The equipment of the churning room in which the sheeted rubber is dissolved or mixed with varnish makers and painters' (V. M. & P.) naphtha, consists of twenty-three multiple-operated Paragon mixers, made by the J. H. Day Co. (See Fig. 11.) The rubber and solvent introduced into the top of the mixers are churned until the product has the desired smoothness and viscosity and then the thick pasty rubber cement is drawn off at the bottom of the mixer. Smaller batches, particularly those for special colored stock, are mixed in pony mixers such as are used in paint mixing.

The rubber cement is discharged into steel or wood





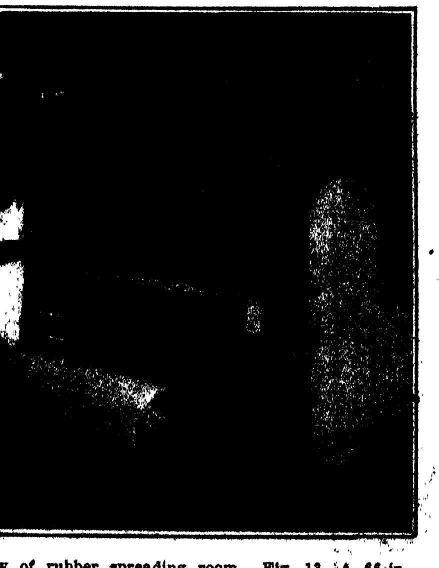


Fig. 9—Milling rubber. Fig. 10—Two Banbury internal rubber mixers. Fig. 11—Battery of mixers for rubber solution.

Fig. 12—A view of rubber spreading room. Fig. 13—A 66-in. rubber calender. Fig. 14—Rubber embossing machine.

tubs, such as are shown in Fig. 11, and these are carried by trucks to the rubber spreaders. These machines, which are to be seen in Fig. 12, operate on the same principle as the pyroxylin coaters—i.e., an adjustable knife edge pressing against a roller determines the thickness of the coat to be applied. The rubber-coated fabric moves out over a platen of steam coils heated by high-pressure steam, which serves to drive off the solvent. After the goods have received the proper weight of rubber coating, the rolls are transported to the embossing room.

For some rubber goods, such as auto-top materials, it is sometimes desirable to produce a double-texture cloth. This is accomplished on a machine known as a doubler, which merely presses together the coated surfaces of two pieces of cloth. Another machine in the same room is the starcher, which gives the silver luster finish usually associated with certain types of rubber goods, such as hospital sheeting, aprons, etc. This effect is obtained simply by dusting a mixture of potato and corn starches on the surface of the coated fabric.

Calender Room Operations

The other and more characteristic method of applying rubber to the fabric is by means of the calendering machine, one of which is shown in Fig. 13. The sheeted rubber must first be warmed, which is done by working or cracking it on a 50-in. rubber mill, such as the one in Fig. 9. Two mills are required for each of the two rubber calenders. The mills are of the same construction as those used for mixing, and they, too, are protected by the safety bars previously described.

The calenders, made by the Wellman-Seaver-Morgan Co., have three hollow chilled iron rolls, 24 in. in diameter and 66 in. wide. They are provided with steam and water connections for proper temperature control. The properly warmed rubber stock is fed into the calender between the two upper rolls and it forms a coat of predetermined thickness on the middle roll. This is then calendered onto the cloth fed in between the two lower rolls from the opposite side of the machine. The calender effect is obtained by gearing which permits the two lower rolls to turn at the same speed while the top roll moves at a slightly different rate.

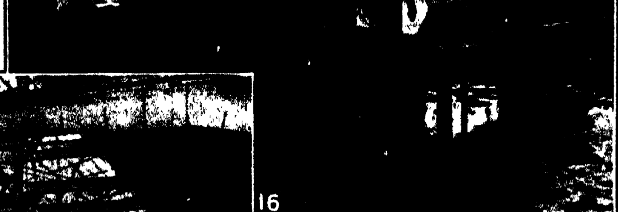
The calenders are driven by a variable speed 45-90 direct-current motor (230 volts, 175-230 amperes) operating through speed reduction gears. Two 240-volt, 165-kw. six-phase rotary converters supply the power to these motors.

As the rubberized cloth leaves the calenders, it is given a thin coat of a quick drying water varnish which prevents the coated surfaces from sticking to the cloth in the rolls and later from adhering to the graining roll during embossing—the next step in the manufacturing process.

Rubber Embossing and Vulcanizing

The fabric that has been coated on the calenders or in the rubber spreading room is taken to the embossing room. In contrast to artificial leather embossing, high pressures are not necessary. Rather a roller embosser is used consisting of an engraved steel roller turning between two paper or fiber covered rolls. The goods are fed in between the two lower rolls, follow around the engraved roll for about 180 deg. and pass out over the upper roll. The embossers are belt-driven through overhead countershafts. As shown in Fig. 14, the gearing and moving parts of these machines are covered for the purpose of protecting the operators.

The embossed material is now ready to be vulcanized. The rolls of cloth are taken to the vulcanizing room and as the goods are festooned into the ovens they receive a coat of varnish in order to give them the luster and finish desired. The vulcanizing ovens are long insulated chambers heated by steam coils. The temperature is automatically controlled and recorded by a Tycos "Thermo-Tyme" regulator. This instrument controls the steam supply so that the temperature is gradually increased for a predetermined period, until the vulcan-



16

Two Views of Dye House

Fig. 15—Continuous dyeing machine with can drier in background.

Fig. 16—Jig dyers showing padder for direct dyes.

izing temperature (about 225 deg. F.) is reached. It is then held at this temperature for an hour or until vulcanization is complete.

Not all of the rubber goods, however, are vulcanized by dry heat. The single texture materials for hospital sheeting, raincoats, etc., are cured by means of sulphur chloride, either as a vapor or in a suitable solvent. The latter is known as the "liquid acid cure." The goods are passed over rolls which apply the sulphur chloride solution, the excess of which is later neutralized with ammonia.

Inspection and Testing

Careful inspection, both physical and chemical, is exercised over all the products of the Duratex Corporation. In the inspection room, a view of which is shown in Fig. 17, both the pyroxylin- and rubber-coated fabrics are examined for surface blemishes. Colors are checked and matched with company and buyers' standards. The material is weighed to see if it is up to standard.

In the chemical laboratory (Fig. 7) samples of all goods leaving the factory are tested for aging and weathering, for tensile strength, resistance to wear, stretching,[1] etc. Ultra-violet light from a Cooper-Hewitt mercury-arc lamp is used for determining color fastness and possible deterioration due to sunlight and exposure. The method and machine of the Bureau of Standards are used for strength determination.

The rubber-compounding ingredients, nitrocellulose, solvents—in fact, all raw materials—are evaluated according to standard physical and chemical tests. The fabrics are judged according to weight, weave and construction, thread count, etc.

Dyeing and Finishing

In addition to the inspection and laboratory testing, other operations common to both the pyroxylin and rubber departments include the dyeing and preparing of the fabrics as well as the power generation and distribution. Practically all of the gray goods used for the production of coated fabrics must first be dyed. Sulphur colors are used on top materials and other goods where it is desired that the product be fast to sunlight. For a considerable proportion of the artificial leather, fastness is not especially essential and direct dyes are used.

Oilcloth which is to be dyed with sulphur colors is first treated with diastase to render soluble the sizing material in the cloth. The removal of the size enables the dyer to obtain more uniform shades.

In the continuous dyeing machine shown in Fig. 15, seven separate baths are used in applying the sulphur colors. The cloth is wetted, passed into a dye bath in which the sulphur colors have been reduced by a sodium sulphide solution, and then into a chrome bath. After a thorough washing, the dyed goods are mangled and dried on the can driers, which may be seen in the background of Fig. 15.

Sulphur colors are also applied in the jig dyeing machines shown in Fig. 16. In this case it is necessary to change the bath for each of the dyeing, developing and washing operations. The cloth is dyed with direct dyes on a machine known as a padder, which consists essentially of a dye box with superimposed squeeze rolls. The cloth is passed through the padder as many

FIG. 17—VIEW OF INSPECTION ROOM

times as is required to obtain the shade desired. All of the dyed cloth must be stretched before it is coated, and a portion of it is napped and felted. The first operation takes place in a machine known as a tenter. This piece of equipment, which is 90 ft. in length, consists of two parallel traveling belts equipped with gripping devices which clutch the cloth and slowly spread it to the desired width as it is drawn through an oven heated by steam coils and forced hot-air draft to a temperature of around 190 deg. F.

The heavier dyed goods are napped on machines in which part the surface threads of the cloth are combed by wire teeth projections on steel drums revolving in opposite directions. There are several reasons for this operation. When the fabric is napped on the under side, it gives the artificial leather an additional pliability and plumpness as well as the soft feel that is often associated with leather. For certain grades, such as "Peelless" artificial leather, the cloth is napped on the side to be coated and then sheared to an even surface that allows the coating a better anchorage.

Unusual Features in Power Plant

The power plant contains a number of unique features that have attracted wide attention among engineers.[2] For its size and the kind of loads supplied, the plant is extremely simple, consisting of a single boiler of 3,330 sq.ft. of heating surface and one turbo-generator. Because of special equipment, including a new type of economizer installed by the Babcock & Wilcox Co., as well as forced and induced drafts, the boiler is operated, at times, up to 350 per cent of its normal rating. It is fired by an automatic Coxe chain-grate stoker. The turbo-generator is of the Rateau type, made by the Ridgeway Dynamo & Engine Co., and has a capacity of 625 kva., operating at 3,600 r.p.m. It generates 460 volt three-phase sixty-cycle power. When operating at 20 lb. back pressure and 500 kw. load, the turbo-generator requires 25,800 lb. of steam per hour.

Low-temperature steam requirements for heating and process work in the plant have been estimated to reach as high as 10,000,000 lb. per month during the winter. Figures for the steam consumed in the individual processes, however, are not immediately available.

The production of pyroxylin- and rubber-coated fabrics, although largely a specialized industry, involves the application of chemical engineering in most of the manufacturing processes. The writer is indebted to the officials of the company for their assistance in the preparation of this article.

Use of Pulverized Coal

The Methods That Have Been Perfected in Cement Mill Practice Form a Basis for Application in Other Industries

THE use of powdered coal as an industrial fuel has spread to such a large extent recently that the methods employed in the cement industry, which was the first industry to use this fuel, will be of interest to all. In *Power* for May 8, 1923, H. A. Schaffer, conservation engineer of the Portland Cement Association, has a paper on this subject. Mr. Schaffer says, in part:

When rotary kilns for cement manufacturers were introduced in this country about 30 years ago, a change was necessarily made from the coke burned in the old-style stationary, vertical kilns. The new fuel had to be one that could be blown into the revolving cylinder to produce instantaneously the intense temperature needed for clinkering the raw materials

At first crude oil was used with good results, but the increasing cost of this fuel in the East, where most of the early plants were located, led to trials of powdered coal. It was in 1897 that this finely ground material was first adopted as fuel for cement burning in several mills.

While crude oil and natural gas are today used in some localities where prices will permit, pulverized coal is the usual fuel. In fact, out of the 115 operating cement plants reporting to the United States Geological Survey in 1921, 92 burned powdered coal only and 6 more employed coal in conjunction with oil or gas. All but one of the remaining 17 burned oil; the exception utilized natural gas.

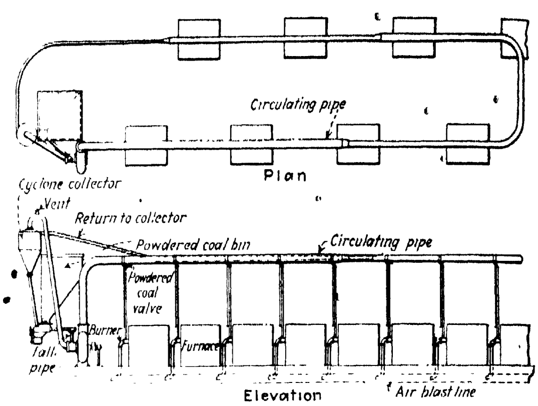
Kiln Fuel Requirements

Of course the fuel problems in the kilns of a cement mill are somewhat different from those met in power-plant practice. For instance, the great heat produced by a flame of pulverized coal is an advantage in cement manufacture. There the raw mix must be heated to a temperature of from 2,500 to 3,000 deg. F. in order to bring about the desired chemical reactions as the materials are burned into the clinker that is later ground into cement. But in a power plant this intense heat introduces difficulties, met to some extent by hollow furnace walls.

Ash, if reasonably constant and not too great in amount, offers no problem in the cement kiln, as allowance can be made for it in proportioning the mix. Apparatus for burning powdered coal in kilns is therefore simpler than that recommended for modern boiler installations, where arrangements for collecting ash must be made and attention directed to preventing injury to the furnace from heat.

In view of the long experience of the cement manufacturers with powdered coal in their kilns the question naturally arises as to why this fuel is not widely used in their power plants. The answer lies in the failures that met their early attempts to secure the advantages of pulverized coal as a boiler fuel, and in the recent advances in the utilization of the hot kiln gases for heating the power-plant boilers.

Various experiments were made in power plants with the crude apparatus early available for burning powdered coal, but none of these trials was altogether successful. Probably the gravest error made lay in the failure to proportion the furnaces to suit the fuel, with



TYPICAL PULVERIZED COAL-HANDLING SYSTEM FOR HEATING FURNACES

a resultant inability to make them stand up in the hard, continuous service demanded in cement-mill operation. As many more pressing problems arose to occupy the manufacturers' attention and the possibilities of waste-heat utilization came to the front, the development of workable methods for burning powdered coal under boilers was left to others more vitally interested in that phase of power-plant design.

Renewed Interest Now Shown

Powdered-coal installations have recently been made in a few cement mills, yet it is hardly probable that a great deal more will be done in this field, simply because the engineers of the industry are working on an even more economical plan.

In most plants the proper conservation of the hot gases leaving the kilns will provide all the heat needed for the boilers in a power station big enough to supply the entire plant. As the power needed to operate the heavy machinery in a cement mill is large, this means a marked saving in fuel. The installment of waste-heat boilers requires a very heavy investment, however, and involves many problems that must be solved for each plant.

In any cases where additional fuel must be bought to generate power, the possibility of utilizing a low grade of coal when powdered is especialy important, for a large quantity of fuel is required to make cement —about 200 lb. of coal to the barrel of 376 lb. when the waste heat is not utilized. Much more than half of this amount is now being pulverized for burning in the kilns, but a big total is still used without grinding to generate power.

In one case a cement plant has been able to burn anthracite silt, coke breeze and bituminous screenings in the same powdered-coal furnace, with satisfactory results. This furnace is equipped with both vertical and horizontal flare-type burners, for use with low- and high-volatile fuels, respectively. In the kilns it is difficult to use even a part anthracite, and the chemical composition of the coal must fall within certain limits.

Handling Powdered Coal

Especially in the field of safety the cement industry can offer valuable experience. In the early days coal dust was not generally recognized as a dangerous explosive, and inexperience resulted in a number of accidents. Since that time safe methods of handling this fuel have been worked out, and a campaign of education under the direction of the Accident Preven-

tion and Insurance Bureau of the Portland Cement Association has greatly reduced the hazard.

Many plants have never had an accident from this source, and with the installation of modern equipment the industry as a whole is making the coal room safe. In 1922 the cement manufacturers of the United States burned over 5,800,000 tons of powdered coal in about 100 separate plants.

Above all, the grinding and conveying equipment should be tight enough to prevent the escape of dust. The coal buildings should be well lighted so that attendants can work with facility, and well ventilated so that there is good circulation of air. Under no conditions should open lights be allowed in the coal house. Magnetic separators should remove all iron from the incoming coal to avoid sparks in the grinders. The coal driers should be separated from the grinding equipment by a fire wall, at least. Experience has shown that danger has been greater to life than to property where accidents have occurred, as the trouble has been caused more by "flares" that severely burn workmen than by explosions that wreck buildings. Employees must be made to understand the necessity of continuous observation of established precautions, and none but trustworthy men should be employed in the coal department. It is not enough to post accident-prevention rules—they must be observed.

For cement burning, finely ground coal has been found essential, as much heat is lost from incomplete combustion when coarser material is used. Eighty-five per cent passing a 200-mesh sieve is considered good. Fine grinding, however, tends to shorten the flame and to make it hotter, so that again the best boiler-room practice may differ from that cited.

In cement mills the procedure is first to dry the coal in rotary driers and then to pulverize it, usually in mills of the centrifugal type or in tube mills after any lumps have been broken up in small rolls or crushers. In a number of cases powdered coal is burned in the coal driers, but this is not such common practice as it is to use this fuel in drying the raw materials before they are ground to a fine powder. In at least one public-utility power plant the driers have been omitted entirely. The practice of pulverizing the material without drying is followed in one or more other cases when coal having a low moisture content is received.

Conservation of Molding Sand

For some years the New London Ship & Engine Co. has been reclaiming molding sand by mixing it with clay in a muller. A refractory clay having high plasticity is deflocculated with alkali and added in correct quantity to the used sand. In fact, merely mulling the sand increases the bond (as indicated by the Doty test on a 1-in. square prism described on p. 860 of our issue of May 14, and also by the dye adsorption test). This fact was reported to the recent meeting of the American Foundrymen's Association by metallurgists from the Hunt-Spiller Corporation, together with additional experiments indicating that a dried and remoistened sand is stronger than one possessing its original moisture. There will also be found a certain percentage of moisture, developing maximum cohesiveness. Other things being equal, the cohesiveness varies greatly with the grain size.

All these facts have considerable bearing on the reclamation of foundry sand—a problem of first importance today. A canvass of 145 plants showed a total of 1,000 tons rejected per working day—usually dumped at a cost of about \$1.50 per ton. This amount of sand equals about one-fifth the total in circulation in the foundries. H. M. Lane has worked on this problem for several years, and has come to the conclusion that not less than 60 per cent of the waste sand can be reclaimed at a profit and successfully re-used if the molders and core makers do not know they are getting it. Various hydraulic classifiers, well known to ore-dressing plants, can be used to separate fine particles from the burned sand, but on account of the expense of drying, Mr. Lane recommends the following procedure: Crush the sand in a ball mill, reclaim metal values by a magnetic pulley, and blow out the fine particles in a cascade separator. Then mix with the proper amount of a "fat" clay and water in a muller, and the sand is ready for re-use. If cores are to be made of it, a binder other than oil is necessary.

F. L. Wolf and A. A. Grubb also described methods in use at the Ohio Brass Co. Floor sweepings are screened, and the material which passes 8 mesh is now reclaimed, whereas it was formerly thrown away. Comparative tests follow:

	Satisfactory Sand	Refuse Sand
Average fineness	128.0	116.0
Dye adsorption	0.062	0.068
Moisture	7.5	5.2
Bond	163.0	144.0
Permeability	180.0	140.0

If the refuse sand is mulled to proper water content, it will produce good castings, but dries very rapidly in the pile. This tendency has been entirely eliminated by mulling the refuse with a calculated amount of fine Ohio sand having high dye adsorption. After this treatment the reclaimed sand has a fineness of 125 and dye adsorption of 0.073, moisture of 6.5 and permeability of 181. It works well in every respect.

Volatilization of Zinc Ores

Behavior of zinc in ores treated by the volatilization process depends largely on the arrangement of the mineral in the ore, also on the atmosphere that is maintained in the furnace during treatment. Experiments made by metallurgists of the Interior Department at the Salt Lake City experiment station of the Bureau of Mines have indicated that in a strictly oxidizing atmosphere little zinc is volatilized, especially in zinc carbonate ores. In zinc concentrates (zinc 30 to 40 per cent, the silver and lead 6 oz. and 6 per cent, respectively), the quality of silver and lead volatilized ranged from 50 to 80 per cent, whereas the amount of zinc volatilized generally averaged less than 1 per cent.

The behavior of zinc is very erratic, the conditions under which it is volatilized probably depending largely on the sulphur content in the ore, which causes a complicated series of chemical reactions. When crude ores high in sulphur content have been treated, most experiments indicated nearly complete volatilization of the zinc, but when the ore was given a preliminary roast to reduce the sulphur content, the amount of zinc volatilized varied considerably.

The presence of zinc in carbonate ores containing silver, lead and zinc indicates that by volatilization a clean-cut separation can be made between the lead and zinc. On the other hand, in treating complex sulphide ores much of the zinc was volatilized in nearly every experiment, and was precipitated in the Cottrell treaters as chloride with the other metal chlorides.

Strain and Fracture in Metals

Notes on Dr. Rosenhain's Recent Lecture Tour—Why Does Slip, Once Started, Stop?—Method for Distinguishing Shock Fractures—Cure for Season Cracking—How to Increase Endurance of Metal to Alternating Stress

STRAIN and fracture link up closely with the title of Dr. Rosenhain's first lecture on "Hardness and Hardening." (See *Chem. & Met.*, May 21, 1923, p. 899.) One way to harden a metal is to strain it. Furthermore, hardness might be regarded as the inherent capacity of the metal to resist strain and fracture. Again, plastic deformation in sound metal is accompanied by slip within the individual crystals comprising the aggregate—hardness is associated with the counter-phenomenon of "slip-interference."

Crystalline Structure of Metals

In view of the fundamental importance to any rational explanation of the experimental facts, it would be well to note briefly two pieces of strong evidence that the tiny granules making up a piece of metal are essentially crystalline in internal arrangement, despite the irregularity of their boundaries. A polished surface of substantially pure metal slightly etched shows these networks when examined under the microscope. Very deep etching of some alloys develops pits on the surfaces, these pits bounded by facets, oriented in a strictly parallel direction within each grain. (Fig. 1.) An easy way to show the essential and close parallelism of these facets is to illuminate the specimen obliquely at such an angle that rays are reflected from one set of planes up through the ocular. All the facets turned one way in one crystal flash bright at the same instant. A rather more striking proof of the similarity of the pitting action occurring on even slight etching—which merely gives adjacent grains different tones of gray—was given many years ago by Dr. Rosenhain. He illuminated such a specimen from two directions with red and green light, respectively. Individual grains stood out red or green in a dark background, as they reflected the corresponding light up the microscope tube or clear outside it, as the case might be.

Of course, the clinching proof is given by X-ray diffraction patterns. These show without doubt that the individual metallic grains are composed of atoms built up in a regular geometric pattern in space. (See, for instance, "Studies of Crystal Structure With X-Rays," by Edgar C. Bain, *Chem. & Met.*, Oct. 5, 1921, p. 657.) Auxiliary lines of evidence show that the atoms (which probably consist of a nucleus and an outer system of electrons) entirely dominate the space they occupy so tenuously. They act like they almost touch one another, they cannot wander about; they oscillate or gyrate slightly about a mean position; and there is in general no room for additional atoms in that closely packed space lattice. Many atoms crystallize in the face-centered cubic system, and in this it is easily shown that along three complementary planes (called the "octahedral planes" by crystallographers) the atoms are arranged with checkerboard regularity.

It is along these octahedral planes that cubic metals such as iron, copper, aluminum and lead slip under heavy load. Of course at low unit loads (within the proportional limit) the crystal deforms in an elastic manner—the whole lattice is pushed and pulled slightly out of square; its normal shape is almost instantly resumed on release of load. But when the load is too great and is applied fairly deliberately, the crystal appears to slip—to part into blocks which move past one another, yet quickly regain even greater stability than they had formerly.

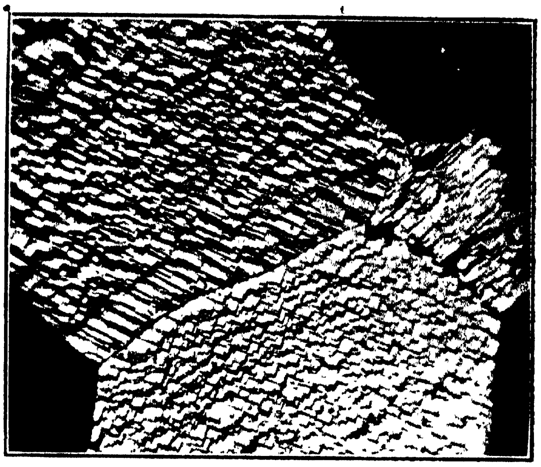


FIG. 1—CRYSTAL FACETS ON THE GRAINS OF SILICON STEEL. (STEAD)

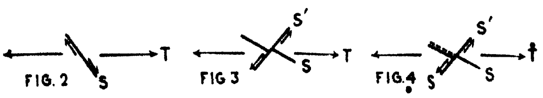
Why Does Slip Stop?

It might be asked, Why does slip stop, once started? In many crystals it does not, especially if the stress is localized by a notch or if the load is suddenly applied with a great shock. Then the crystal does break across with a true cleavage fracture. But that is somewhat beside the point, for normal plastic flow is accompanied by intermittent slip. Dr. Rosenhain pointed out the fact that slip is a gliding motion, not a sliding one; movement involves an interchange of atomic bonds rather than a breaking of bonds. Therefore we find slip to occur along those planes where atoms are packed with greatest regularity and at shortest distances so that they may change partners like dancers in the "grand right-and-left," constantly changing yet never free. Indeed a test piece of brittle zinc made up of a single crystal the basal plane of which (where the atoms are regularly spaced) is set at about 45 deg. to the direction of pull, has been elongated several thousand per cent before fracture!

Furthermore, it is most probable that certain bonding actions occur between whole groups of atoms, and for that reason the atomic movements involved in crystalline slip involve a gradual transfer and not a simultaneous change. In other words, the first region is rapidly transferred or propagated to its next adjacent

layers—an action similar to that evidenced on a large scale by the drop of beam and its recovery in a tension test. But the atomic bonding is never destroyed completely; some regions of the disturbed surfaces take hold again in their exactly normal spacings with their neighbors, others never do. The latter constitute the disturbed atoms of the amorphous phase at the "surface" of slip—surface does not mean a definite plane, because slip occurs throughout a layer many atoms thick, and disturbs that layer profoundly. Such actions destroy the very mechanism of slip by disorganizing the crystallinity of the region, whereupon slip must stop. Crystallinity, slip and plastic flow are con-



FIGS. 2 TO 4—SLIP STOPS BY THE MOVEMENTS ALONG CONJUGATE PLANES

comitant phenomena, as is developed at length by a consideration of hardening.

Slip, therefore, looked at in this light, has a "self-stopping" tendency. Dr. Rosenhain is of the opinion that this tendency is not wholly sufficient, but is reinforced by the fact that a cubic crystal develops simultaneous slips on intersecting planes. Suppose, for instance, that by virtue of a tension T, slip occurs along a plane of maximum shear S. (Fig. 2.) Quickly thereafter—almost simultaneously—the same thing occurs on a conjugate plane S'. (Fig. 3.) This fractures the first plane, it becomes "stepped," as it were, and in order for further movement to occur along the first plane and direction, it would be necessary for new movement to be initiated in fresh material, as indicated by the dotted line in Fig. 4. Furthermore, the amorphous metal generated along S' would have to be broken through as well. Now consider the fact that not only two but three octahedral planes are simultaneously operating in a ferrite crystal, and that slip occurs not only in one but many planes along each direction, and it may be concluded that the various intersections will speedily lock each other.

In all such actions taking place in fine-grained metal, the influence of the crystalline boundaries in halting slip is evidently large. Not only is a certain amount of end support given, but it is necessary for the plane of movement to change in direction. Such factors are powerful preventives of rapid crystalline fracture by cleavage breaks. Therefore under steady, slow stress, the crystals are normally observed to slip, first here, then there; finally all of them have changed their shape and elongated to a noticeable extent. As deformation proceeds the crystals shred out gradually and finally the metal possesses every appearance of being "fibrous." (These "fibers," however, are much elongated crystals, highly intersected by surfaces of slip.) At last possibility for further slip has been exhausted and the individual crystals finally break across the altered layers, in a direction sharply inclined to the direction of strain. Even here it is important to remember that the crystals are broken across their body, not torn apart from one another. This can be demonstrated by microscopic examination (Fig. 5) if the broken surface is carefully protected by a thick copper-plate (electro-deposit).

However, there are instances when ductile crystals may be fractured by cleavage and with no apparent deformation. For instance, a thin sheet of very pure iron, if cold-rolled and properly heat-treated, will be made up of very large crystals, extending completely through the sheet from face to face. Now if this sheet is bent in a correct manner, so as to throw tension only along the octahedral planes of the single crystal, a brittle break with no extension will result. Pulled apart otherwise, the sheet as a whole necks down sharply and breaks after ductile flow.

Again, if a bar of tough wrought iron be notched sharply on all four sides, held in a vise and struck with a hammer it will snap off like a glass rod. If such a break is copper-plated and a normal section examined, it will be found that it follows long facets across large groups of crystals, passing from group to group with small change in direction. Crystals have not been torn apart, they have not even deformed, but apparently split open. A simultaneous development of Neumann bands in the ferrite crystals undergoing impact stress is an important side issue. Dr. Rosenhain regards them to be the "echo" of cleavage fractures by shock.

Path of Fracture in Mild Steel

So much for slip in pure metal, or in the uniform crystals of solid solution. How does mild steel behave, with its two constituents, soft ferrite and harder, less ductile pearlite?

Tested in tension, it might be expected that the fracture would occur in the softer ferrite, but actually it passes through pearlite volumes as well, although the ferrite crystals are shredded out. Apparently the less ductile pearlite does not develop brittle breaks until the last end—it is held up to its work on all sides by the surrounding meshes of ferrite. Finally, when the pearlitic masses must assume considerable extension, they break short across, throwing their loads into the surrounding ferrite, which in turn breaks, joining up to the cracks in the harder constituent. Thus it is that the surface of rupture passes indiscriminately across both. (Fig. 6.)

Fig. 5—Broken ends of elongated crystals; fracture copper-plated before sectioning. (Rosenhain).

Shock failures, on the contrary, follow the ferrite meshes exclusively or nearly so, simply because the cleavage planes developed by sudden impact are much more extensive and continuous in that constituent than in the laminated pearlite. This characteristic is a very good method of distinguishing whether a failure was caused by gradual or sudden overload.

Intergranular Cement

It is now interesting to inquire what kind of matter is present at the grain boundaries in normal metal, since these regions always hold together even when the metal is broken either after slow stressing or by shock.

Obviously when two crystalline bodies grow toward each other by adding on atom by atom, their junction will be filled with atoms which to an unknown depth

will be pulled both ways. It may be that the transition from one crystalline orientation to another may be gradual, accomplished step by step; it may be that there are a great number of little crystallites of colloidal size and with independent systems existing there; or it may be simply a heterogeneous mass of no order whatever. At any rate, there is evidence that a layer of considerable depth exists here, the properties of which differ from those of a sizable crysta

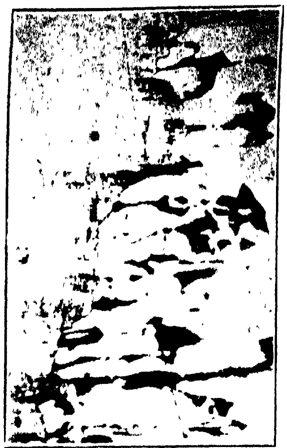


Fig. 6. Slow tension fracture, across both ferrite and pearlite in mild steel (Rosenhain)

Any of these suppositions as to the nature of the cementing material postulate a substance which cannot deform by slip. It can only move after a clear break which pulls atom from atom. No plane surfaces exist along which interatomic forces are of similar intensities, and along which slip can take place. It is known that breaking atom from atom requires vastly larger forces than does slip—the cohesion atom to atom is very large. The lecturer likened the two actions to this: Take two smooth plates; moisten each slightly with a few drops of liquid and rub them closely together. It requires comparatively little force to slide one past the other, but a very great force indeed to pull them directly apart.

Such great strength residing at the crystal boundaries at low temperatures suggests the presence of amorphous material. Non-crystalline metal is really a supercooled liquid like a glass; viscous, brittle and hard at ordinary temperatures but softer and weaker at higher temperatures.

While even the most drastic quenching of a fine spray of pure metal produces beads which when examined are seen to be made up of small crystals, it does not necessarily follow that *all* metal is crystalline. In fact, we can get alloys which, when compared to the same material after radically different heat-treatment, possess all the properties we would expect of amorphous material (arguing from analogy to solid substances known to contain no crystalline matter).

Thus it is known that the viscosity of a liquid is very low; if it can be undercooled like a slag without crystallizing, it has no definite "freezing" temperature or even temperature range; its viscosity increases at an increasing rate until, as indicated in Fig. 7, it reaches a very high value. In the liquid state, above the crystallizing temperature, the mass is composed of single atoms free to move; the viscosity and strength are quite low. As the mass cools the atoms aggregate into groups and ever larger particles and the mobility of each is greatly diminished, viscosity and strength multiply rapidly to millions of times those of the liquid until finally, past a "threshold temperature," the whole mass is as one group of helter-skelter atoms and viscous motion ceases. Below this temperature there must be an initial stress of appropriate magnitude before any motion occurs in the material at all.

If that same melt, instead of being undercooled, is allowed to crystallize, the viscosity and strength of the material enlarges greatly at the crystallization temperature, and on further cooling increases somewhat, but at nowhere near the rate which the amorphous material assumes. The viscosity-temperature (and inferentially the strength-temperature) curves intersect at a point dubbed the "equicohesive temperature" by Dr. Jeffries. (*E*, Fig. 7.) (See *Trans. Am. Inst. Metals*, 1917, p. 300.) Below *E* movement under stress must take place in the crystal by slip long before the amorphous material of its joints would break. Above *E* the opposite is the case. In fact, if the metal could be held at temperatures just below freezing, failure ought to occur at very low stresses and should be by pulling the grains apart—in other words, failure should be intercrystalline rather than transgranular.

Experimentally this has been verified beautifully. Lead—a very ductile metal—when tested in tension at room temperature draws down nearly to a knife edge before breaking. But hang up a bar long enough to give a stress near its support of say 4 lb. per sq.in., maintain it carefully 5 deg. below its melting point, and in a short time the bar will pull itself apart, with a brittle fracture having no extension or contraction in area. Other metals show the same phenomenon. Microscopic examination shows without question that such failure occurs by pulling the crystals apart at their boundaries. Likewise it has been proved that the trouble is not caused by the melting of an impurity occurring at the grain boundaries, first because intercrystalline fractures can be produced at successive temperatures (lower than the melting point of the most fusible phase, but above *E*) by imposing a higher stress or giving it a longer time to act. Second, gold with a certified purity of 99.999 is no exception to the rule.

Failure at Grain Boundaries

One very curious method of failure has been termed "season cracking." Such things as cartridge cases, tubing and utensils spun from thin metal of brass, aluminum, purest lead and even iron have at times developed cracks after years of use or storage, and for no apparent reason. When examined, failure is always found to be intergranular, and the metal always appears to contain internal stresses of considerable magnitude—either residual from the last manufacturing operation or imposed from outside sources during use. It springs apart after failure, or if small portions of the material be very carefully removed the two pieces deform somewhat so that they will not fit together again. If a test

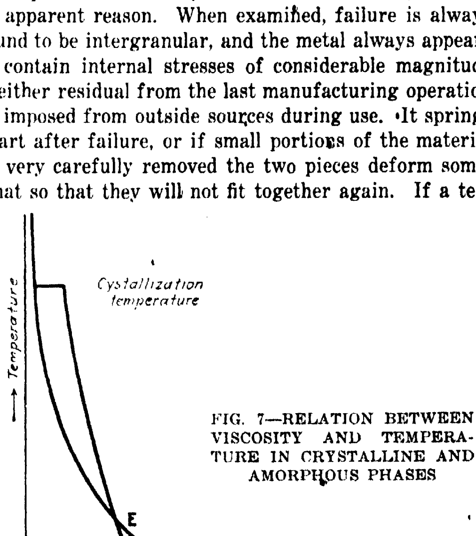

FIG. 7—RELATION BETWEEN VISCOSITY AND TEMPERATURE IN CRYSTALLINE AND AMORPHOUS PHASES

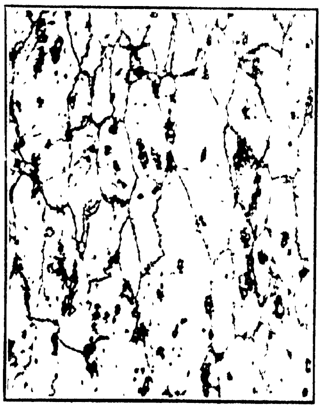
TABLE I

Stress, Lb. Per Sq.In.	Time to Produce Fracture	Nature of Break
54,000	2 min	Transcrystalline
36,000	9 min.	Partly intergranular
31,000	31 min.	Partly intergranular
29,000	56 min	Wholly intergranular
18,000	3 weeks	Wholly intergranular

piece be cut from such a defective article and broken in a testing machine, the bar will neck down and will show a perfectly normal transcrystalline rupture on slip-planes. Therefore there is no inherent weakness in the material. In this and other ways it has been proved that season-cracking is caused by a long-continued low stress.

These facts involve the movement of something in the metal which is unyielding against loads applied with moderate speeds, but yielding to loads applied with extreme slowness. Is not this a characteristic of amorphous material like pitch?—fragile to a blow but slowly engulfing a hammer laid upon it. This inference is fortified by experiments on a 3:20:77 Cu:Zn:Al alloy. Identical test pieces were made up and different loads hung on. Time for fracture was then recorded as given in Table I. If these results be plotted on semi-logarithmic paper, they locate a straight line, exactly as does a plot of the law of viscous flow. On long slow loads far below the elastic limit of the crystal the intergranular material in this alloy yields slowly and eventual fracture occurs by pulling the grains apart.



FIGS. 8 AND 9—ALLOY "A" (3.20·77 Cu Zn Al). × 150
Fig. 8—Intergranular crack in over-annealed piece.
Fig. 9—Stable metal after annealing at 250 deg. C.

Will any metal fail thus if given a long enough time under moderate stress? Dr. Rosenhain believes this depends upon the shape of the crystals; if they are very smooth, he would answer "Yes." If, on the other hand, the crystal boundaries are rough and interlock somewhat, "No." Under the latter circumstances a little yield in the boundary metal will alter the stress distribution—eventually nearly all the load will be carried by the interlocks on the crystals. This assumption is also verified by experiment. If the Cu:Zn:Al alloy mentioned above be tested in the rolled condition, it is free from intergranular rupture on prolonged loadings. This is true even if the metal is reheated to 450 deg. C. and a reduction of 50 per cent then given. However, if such safe material is annealed (1 hour at 425 deg. C.), the alloy will have the microstructure of Fig. 8 and intergranular breaks result. Annealing at temperatures below 250 deg. C. retains the rolled structure of Fig. 9, and the metal is immune from accelerated season-cracking. (See "Eleventh Alloys Research Report," p. 177.)

Many investigators have found that certain corrosive agents hasten season-cracking very much. In fact, immersion in mercurous nitrate is often specified for acceptance tests of cold-worked brass. If dangerous internal strains exist, the crystal boundaries are parted in a few seconds, probably by a selective corrosion of the amorphous metal at those places. Traces of ammonia gas in the atmosphere are accelerators of season-cracking. Dr. Rosenhain likened the action to two pieces of paper held together with soft gum. If the pieces were pulled apart quickly, the paper would tear, leaving the joint intact. If the pulling was very slow, the joint would slowly split, while if the joint were steamed slightly it would lose almost all its coherency. (However, chemical action is not necessary to explain the facts of Table I. That alloy while being stressed has been rigorously isolated from oxygen in a vacuum or in an atmosphere of hydrogen. Time of rupture is about twice as long as the periods noted, but intergranular rupture is still unquestioned.) Similar data have been noted in the action of caustic soda and molten nitrates on steel boilers. Bent boiler plate or cold-worked metal for such service should be normalized rather than given an anneal below the Ac range.

The so-called fatigue fractures constitute a last category which should be examined. If a metal is mildly overstrained once, and then allowed to rest, the amorphous metal generated at slip-planes and crystal boundaries may recrystallize to a certain extent—or at any rate the lesion appears to heal. If, however, the first overstrain is immediately reversed, and motion on the crystalline slip-planes is in great part reversed, the first lesions cannot heal, but actually extend themselves.

Experimentally this is observed as follows: If a piece of pure iron be given several thousand such alternate stresses, certain crystals will develop short markings which can be seen under the microscope. These markings, on continuing the experiment, grow endwise clear across the crystal, and gradually multiply into what are undoubtedly cracks. Finally the piece breaks—the fracture follows a succession of these fissures; if the stresses have been high, the final appearance is quite typical of coarse-crystalline metal broken under shock. In passing, it may be said that it is this appearance which has led to the mistaken idea that alternating stresses cause metal to crystallize.

The most important physical property for many classes of service like shafting and axles is the endurance limit of the metal—i.e., the stress which may be repeated an indefinite number of times without starting the first tiny internal fracture. This property is closely allied in magnitude to the stress which causes the first slip in the metallic crystals. Determining the proportional limit in tension does not register this value, since permanent deformation in individual crystals might have occurred long since. Furthermore, the metal may have previously been strained, and have acquired thereby a fictitiously high elastic limit. Consequently

an actual series of endurance tests is necessary to determine this important property, a matter which requires many long-continued experiments to determine satisfactorily, since it has been shown that specimens will break after 60 million alternations.

Many investigators have worked on this problem, notably Prof. Haigh at the Royal Naval College, C. E. Stromeyer at Manchester, D. J. McAdam at Annapolis (*Chem. & Met.*, Dec. 14, 1921, vol. 25, p. 1081) and Messrs. Moore and Kommers at Urbana (*Chem. & Met.*, vol. 24, p. 370; vol. 25, p. 1141), and at the present time a series of important tests are under way by the British Aëronautical Research Committee. Some striking results have already been published by Prof. C. F. Jenkin of Oxford. (*The Engineer*, Dec. 8, 1922, p. 612; *Chem. & Met.*, May 7, 1923, p. 811.) In these articles he interpreted or predicted many obscure fatigue phenomena by means of an ingenious model.

Such information has fortified Dr. Rosenhain in his belief that we have at present some short methods which give the true endurance limit of a metal. Stromeyer proposes that the evolution of a considerable amount of heat in a fatigue specimen should mark the load where alternating slips begin in the highest stressed crystals. An even neater and handier scheme has been devised by Gough in the National Physical Laboratory (see *The Engineer*, Aug. 12, 1921) and on experimentation checks known endurance limits to within 5 or 6 per cent.

In this method a Wohler test (rotating cantilever) is fitted with a mirror perpendicular to the axis and on the projecting end of the specimen. As the load is gradually applied, the deflection in the test piece causes the mirror to describe a conical surface. A reflected beam of light will therefore be broadened slightly with increasing bending, until presently the band of light suddenly expands. This marks a discontinuity in the load-deflection relationship, and as before noted, agrees with the endurance range very closely.

Raising the Endurance Limit

By means of such rapid tests many curious things have been discovered about the relation between elastic properties and endurance of various metals. Suffice it to say that it has been found possible to raise the endurance limit 20 per cent or more by the following procedure: First "normalize" the metal by a suitable heating followed by a fairly rapid cooling. Then, with a knowledge of the proper stress range for this material, "fatigue harden" it by a series of stress cycles, each run having a higher load applied, but each run separated from the next by a period of rest. After that, any further heat-treatment should be strictly avoided.

Such a method has been long utilized, without knowledge of its full significance. No marine engineer ever starts up a ship's engine at full load. He coaxes it up gradually. He may have had as a central idea to "run the bearings in"; the greatest advantage was that he raised the endurance limit of the entire machine.

It is also perhaps unnecessary to dilate about the effect of surface finish and internal soundness upon fatigue resistance. Failure starts at the highest stressed crystal. Notches, either scratches, dents or angles in the outer surface, or checks, inclusions or holes inside the metal, cause stress concentrations in their immediate vicinity several times the average. Perfect, even polished, surfaces on soundest metal must be had to insure best service under alternating stress.

The Future of Chemistry in the Iron and Steel Industry*

By Bradley Dewey
Dewey & Almy Chemical Co., Cambridge, Mass.

Every phase of steel-making development has been a triumph of organization. Today the progress of chemistry, applied theoretical physics and chemical engineering is usurping the place and leadership held during the last 40 years by the progress of mechanical engineering and electricity. With chemistry growing so fast, we now have the problem, How is the steel industry to organize this growth?

A generation ago a doctor was a doctor, and a chemist was a chemist. Just as medicine has grown so large that no one man can know it all, so chemistry has grown to a point where there are many distinct fields and where the problem of correlating and using the available information is becoming increasingly difficult. The specialized steel chemist will be the first to admit that he cannot give proper and adequate service to the daily operation and routine development of his organization and also correlate and apply the possibilities of these specialized fields. Consider a few examples.

Some men are obtaining an adequate visual picture of the makeup of an atom. Will this work help the technology of steel? Who is going to tell us why ¼ per cent of copper retards the atmospheric corrosion of steel? Is it going to be a physical chemist or a colloidal chemist? Will the answer open up new possibilities?

Lubrication has been considered a part of the field of the mechanical engineer, but the application of modern colloidal chemistry is opening up new vistas, and the problems incident to the lubrication of hot roll necks, bearings flooded with water, wire drawing and the like are well worthy of review by the best of the new school of chemists.

There are prospects that, through liquid air, we may obtain oxygen in the neighborhood of $5 per ton. The large use of this would, of course, bring with it a host of problems for the specialist in refractories, but would it not also bring with it problems for the best of our physicists and physical chemists? Some may dream that it would even make giant superpower gas producers of our blast furnaces, and make pig iron a byproduct.

The processing of all kinds of fuel, the complete gasification of coal and the structure of cokes made by newer processes call for imagination reinforced with up-to-date technical knowledge. The same is true of the problems incident to the possibilities of saving fuel through central station distribution of high-pressure gas made by new methods.

In short, the chemical organization of the steel and iron industry of the future must make use of specialists in physics, physical chemistry, radio-activity, metallography, special precision instruments, metallurgy, absorption of gases, electrochemistry, electric furnaces, heat-treatment, refractories, thermodynamics, phase rule diagrams, spectroscopy and also chemical engineers of both specialized and consulting experience in the great host of other process industries.

When planning the future of chemistry in the iron and steel industry, the steel executive must apply his best talents to the mechanism and organization which are to employ this ever-increasing mass of knowledge.

*Discussion of a paper on "The Value of Chemistry in the Iron and Steel Industry," read by W. A. Forbes before the recent meeting of the American Iron and Steel Institute.

Is the Sulphur Market Stable?

Healthy Competition in the Market and Production Greater Than Probable Requirements Indicate an Affirmative Answer

By Albert G. Wolf
Texas Gulf Sulphur Co., Gulf, Tex.

If THE history of the world's sulphur industry were plotted prior to the advent of the Frasch process in Louisiana, using time and relative prosperity as co-ordinates, the curve would show some rather violent swings. From that time on, however, we should have to consider the American and Italian industries separately. The two branches of the curve would then diverge, the Italian going downward and the American steadily upward. This increase in domestic prosperity is a reflection of the great increase in consumption due largely to the growing demand for sulphur in sulphuric acid manufacture and the increasing usefulness of this acid to mankind.

Brimstone in Industry

The use of sulphur in the manufacture of sulphuric acid has been the controlling factor in the prosperity of the industry in the past as at the present time. Italy, chiefly Sicily, was probably the first producer of sulphur in quantity, and supplied the European demand in the early days of acid manufacture. During the period from the middle of the eighteenth century to 1839 all the sulphuric acid of Europe, except Nordhausen acid, was made from brimstone. In 1838 the Neapolitan Government granted a monopoly on the exportation of sulphur to Taix & Co., of Marseilles, and that firm raised the price from $25 to $70 a ton. The following year pyrites was used commercially for the first time in the manufacture of sulphuric acid in England. This substitution was also made in all the continental plants, resulting in a permanent setback to Sicilian sulphur.[1]

Sulphur is now an absolutely essential commodity, no matter in what original form it may be produced. Through the recent replacement of pyrites by sulphur in many plants for the manufacture of sulphuric acid, it is now vastly more important to industry than it was a few years ago. But the question is asked: Is the market for sulphur sufficiently stable and the industry permanent enough to warrant manufacturers who require sulphur dioxide in their processes changing from pyrites to this source of supply? In this article the question has been answered in the affirmative.

To quote from a statement by Mr. Frasch regarding the condition of the Italian sulphur industry during the period preceding the introduction of his process in America: "The ups and downs of the Sicilian sulphur business are extraordinary. The people, a large percentage of whom are employed in the mines, are very poor and used to be in the hands of dealers and usurers, who manipulated the sulphur market to suit themselves, and extremely high prices and extremely low prices followed each other as suited their conveniences."[2]

Another sulphur crisis occurred in Sicily in 1894-95, after which the native sulphur sold below the cost of English sulphur recovered from the waste products of the Leblanc soda process. The Anglo-Sicilian Sulphur Co. was then formed by English capitalists, and handled most of the Sicilian output until 1906. During the first few years of its life this company made big profits, later it lost heavily, because of a misguided attempt to compete with Louisiana sulphur.

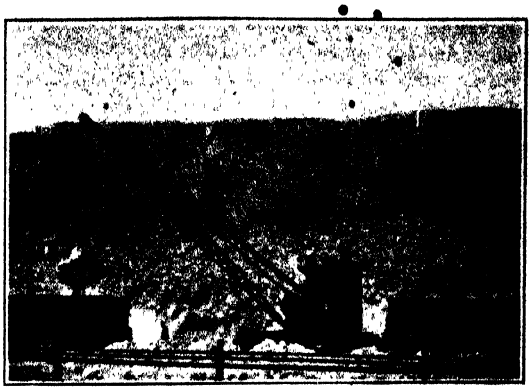


FIG. 1 LOADING CRUDE SULPHUR BY LOCOMOTIVE CRANE

When the English contract with the Sicilian producers expired there was 450,000 tons in stock piles at the mines, and the inroads on the business by the Union Sulphur Co., of Louisiana, were so serious that the Italian Government sent a commission to the United States to investigate the Frasch property and methods. Following the report of this commission, which was decidedly pessimistic regarding the Italian sulphur prospects, that government forced all the Sicilian producers into an obligatory trust or *Consorzio* for a period of 12 years. This occurred in August, 1906. The Italian Government then insisted that American sulphur keep out of European markets entirely, and tried to compel the Union Sulphur Co. to agree not to sell abroad. The refusal of the American company to accede to the Italian demands resulted in a price war in the United States, which soon eliminated foreign competition in this country.[3]

In America the sulphur industry may be said to date from the early part of the present century. Herman Frasch conceived the idea of his process for mining sulphur in 1890, and the first sulphur was produced in 1895. It was not until 1904, however, that the Union Sulphur Co. began making an appreciable output. From this time on the development was rapid. In 1903 nearly 200,000 tons was imported, but by 1913 imports had decreased to 20,000 tons. During this same year about 90,000 tons was exported.

Sulphur was discovered in 1901 at both Bryan Mound, Brazoria County, and Big Hill, Matagorda County, Texas. Mining at Bryan Mound was started by the Freeport Sulphur Co. in 1912, and at Big Hill by the

Texas Gulf Sulphur Co. in 1919. The former, a relatively small producer when compared with the other two coastal mines now operating, did not begin to make its maximum output until it could be readily absorbed by the war demands. The Texas Gulf Sulphur Co. entered the market after the war and at what appeared to be a bad time to offer such an additional supply to the trade. But, by seeking new outlets for its products, and by reviving old ones, especially that in sulphuric acid manufacture, this company secured its share of the business without causing a ripple on the placid surface of the industry. Furthermore, because of its large potential supply, it aided greatly in stabilizing the market to the consumer.

The enormous increase in production of sulphur in the United States probably is not realized by many. Table I shows the great increase in consumption, the decrease of the United States imports to the vanishing point, and the gradual acquisition of the European market by American producers.

The effect on our foreign competitors is well shown in the declining production in both Italy and Japan.

The present price of sulphur is low, perhaps $6 per gross ton less than pre-war prices, whereas the present prices of most chemicals, as other commodities, are considerably higher than pre-war figures.

What Stabilizes the Sulphur Market?

Nearly all the factors influencing the price of sulphur are stabilizing. This is a favorable condition for the manufacturer using sulphur, because the stability of his business is affected by the accuracy with which he can estimate the prices of the raw materials that he will require. One of the chief factors in maintaining a relatively low price for sulphur is the price of pyrites, since sulphur is sold in direct competition with pyrites, both domestic and foreign, in the sulphuric acid industry of the United States.

[4]"Mineral Industry," vol 30 (1921), McGraw-Hill Book Co., New York.

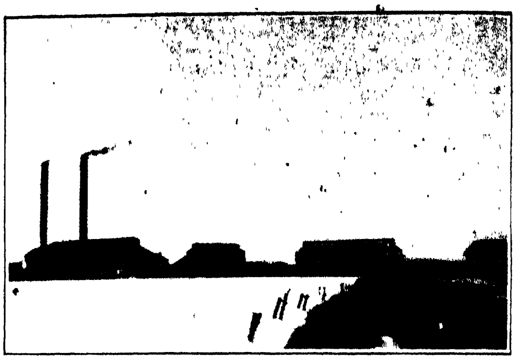

FIG 4—STEAM PLANT, MACHINE SHOP, WAREHOUSES AND RESERVOIR AT GULF, TEXAS

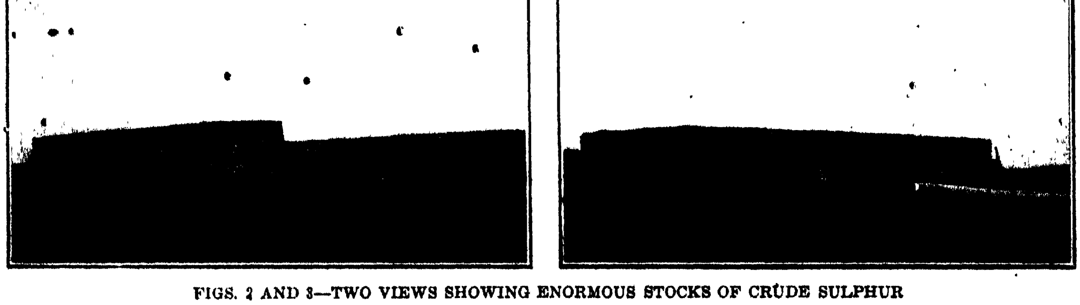
There are many other factors[5], however, tending to stabilize the price of sulphur. One of the most important is that there are three large producing companies in this country, with big ore reserves, all operating independently. This creates a state of healthy competition in the market. These mines are capable of producing in excess of two million tons a year, a quantity greater than the present yearly requirements or probable future demands for many years to come. This eliminates any likelihood of a shortage of raw material, even if the demand were to increase greatly. An excess of production over consumption is not likely to lead to a price war, because sulphur is easily stocked and does not deteriorate. Furthermore, a large stock on hand is desirable from the standpoints of both consumer and producer, for it readily takes care of yearly and seasonal variations in demand. Stocks at the mines are probably two million tons, and present production is about equal to consumption.

The market for sulphur is growing larger both at home and abroad; the normal annual increase has been estimated at 10 per cent. This permits the producer to make a large-tonnage production, which is reflected in his costs, and enables him to sell brimstone at a price that is attractive to the acid manufacturer as compared with that of sulphur in pyrites. Consequently, the price is reasonable to the rest of the trade. Furthermore, this market is not likely to shrink, any fluctuation in demand being due only to general economic changes. In fact, as new uses for sulphur are found, the total consumption will continue to increase.

[5]EDITOR'S NOTE Still another stabilizing influence on the sulphur market is the agreement between American and Italian producers, which was reported on page 828 of *Chem. & Met.* for May 7, 1923. By this compact prices are to be fixed from time to time with reference to economic conditions in the individual consuming countries. The world consumption has been apportioned between the two producing countries and arrangements have been made for settlement of disputes by arbitration. The duration of the agreement is fixed until Sept. 30, 1926.



FIGS. 2 AND 3—TWO VIEWS SHOWING ENORMOUS STOCKS OF CRUDE SULPHUR

Although the majority of the factors affecting the sulphur market tend to maintain its stability, there are certain influences at work, which are of minor importance to the market as a whole, but have their influence on the producer. In fairness to him and in order to complete this review, at least two of these should be mentioned here. They are taxes and freight rates. Recently the state legislatures of Texas and Louisiana considered the passage of certain tax bills, called severance taxes and gross-production taxes, on natural products. These taxes are in addition to the usual property and profit taxes. One such tax proposed is as high as 5 per cent of the gross returns. It is hoped that no such burden will be placed upon this comparatively young but extremely important industry. Freight rates in certain parts of the United States are in favor of pyrites, and are considered by many to be out of proportion to the relative values of pyrites and brimstone in the acid-making industry.

Sulphur Facts and Figures

At risk of repetition, a brief review of the main facts and figures affecting the sulphur situation is as follows:

Present Rate of Production—Probably equal to consumption.

Potential Production (By this is meant the tonnage capacity of the plants already installed, and the ability of the mines to produce up to that capacity)—In excess of 2,000,000 long tons per year, or nearly double the present requirements.

Stock Piles—Approximately 2,000,000 long tons—far more than enough to take care of yearly and seasonal variations in demand, and sufficient to fill orders for 2 years if all three mines were compelled to close down temporarily, a contingency not likely to arise.

Ore Reserves—The developed tonnage of sulphur cannot be stated with the same degree of positiveness as in the case of ore "blocked out" in a mine or quarry, but a reasonable estimate is 30,000,000 long tons. This does not take into consideration the possibility of other discoveries in the future. That such discoveries will be made is an almost assured fact, for the coastal saltdome area, incompletely tested for oil, is even less thoroughly prospected for sulphur.

Increased Demand—A greater demand would not tend to raise the price; on the contrary, it would permit the producers to operate at higher capacity and with greater efficiency, and, therefore, at lower cost. This would mean a continuance of low-priced sulphur.

Record Output of Pyrites, 1921

According to a recent report of the U. S. Geological Survey the domestic production of pyrites increased in 1921 by 49 per cent in quantity and by 55 per cent in value over the corresponding figures for 1920. The output reported was 157,118 tons, valued at $711,432. California contributed 63 per cent of the total and New York and Wisconsin supplied most of the remainder. The imports of pyrites, 216,229 tons, as compared with 332,606 tons in 1920, were the smallest recorded since 1896. This is striking evidence of the increasing competition offered by domestic sulphur.

As indicated in the preceding article, 1921 was also a record year for the sulphur producers. The output of 1,879,150 long tons was valued at approximately $17,000,000. Roughly, about one-half of the total was shipped and the remainder was held at the mines.

How to Improve Paper and Pulp Production

Mill Superintendents of the Paper Industries Discuss Problems at International Convention, Springfield, Mass., May 31-June 2

The recent convention of the American pulp and paper mill superintendents proved to be one of the best ever held by the association. Technical papers were presented covering the most modern phases of mill practice, including among many others the efficient use of logs in the woodroom, improved sulphite control and the prevention of losses in the sulphate practice. The general subject of waste attracted keen interest.

The technical sessions of the convention included papers by manufacturers of equipment and supplies. L. M. Booth, of the Booth Chemical Co., showed that by the addition of a dry coagulent to the white water from the machine, the loss of fiber can be almost completely eliminated. In mills where the water supply is limited, the waste water is made fit for use by the same process. The cost of fiber recovered is approximately 1 cent per pound.

The use of screen save-alls as a sure, cheap and reasonably efficient means of pulp recovery was discussed by A. W. Nason, of the Green Bay Foundry & Machine Co. He pointed out that with fine writings 100 per cent fiber recovery is often undesirable. To make complete recovery of white water fiber possible the use of a large settling tank taking care of all effluent was suggested. The settled suspension in the bottom is used again in the beaters, while the clearer liquid on top is used on the showers, etc. In this way very nearly a closed system results.

Pulp Superintendents Discuss Chips

Woodroom economy, although sacrificed in many mills to feed boiler fires with needless waste, is well worth while. Theodore Safford, of the Raquette River Paper Co., showed that careful attention to chipper knives consists in keeping them sharp, correctly adjusted as to angle depending on condition of wood fed, and provided against damage due to poorly gaged end thrust of the disk shaft. In the course of the discussion it was shown that the grading of chips according to size actually results in sufficient increase in pulp production to make the increased care worth while. The decreasing supply of pulpwood eventually makes the efficient operation of the woodroom absolutely necessary.

Use of Suction Rolls Increasing

Suction couch rolls are being used with increased success on paper machines following years of development work. Harold Bing, of the Sandusky Foundry & Machine Co., pointed out that the use of suction rolls in place of suction boxes results in greatly increased durability of cylinder felts due to reduction of friction and constant maintenance in clean condition. An analysis of the manner in which the water in the wet paper is removed by the suction roll shows that part is taken out by direct pressure (equal to difference between that in room and that in roll), part by atomization and part by absorption. On cylinder machines, the suction rolls usually work best in connection with a top press roll. This increases the pressure on the paper web, with corresponding increase of amount of water removed. On

many grades of paper the use of two felts may be reduced to the use of one by this means. The suction press on the Fourdrinier machine does away with breaks at the wet end by removing all excess water at the bite of the press rolls. In this way also by delivering a drier sheet to the drying rolls the speed of the machine may be increased—has been increased in many installations. The power consumption of these rolls, although considerable, is usually offset by the advantages mentioned, with the result that the net cost of production is diminished.

The sulphite mill presents so many problems that neither beginning nor end of standardized practice is in sight. Of 129 sulphite mills on this continent hardly two operate alike—that is, use the same size chips, same acid, same digester pressure and cooking time. It is only in control of these factors that improved operation can come. O. L. Berger, in his paper on this subject, makes the point that sulphite operation begins with getting good material at a fair price. The same spruce wood would vary more than 100 per cent in price, depending on size, length and condition of logs. An innovation in digester practice that is very promising has been made in Price Brothers' mill at Kenogame, Que. Hot liquor and gas from a digester being blown are passed into another digester just being brought up to pressure. Reports from the mill indicate greatly reduced use of steam, increased yield and a stronger and cleaner pulp. Patents on the process have already been taken out.

A paper by Edwin Sutermeister, chief chemist of the S. D. Warren Co., on losses in making soda fiber, dealt with many of the same factors that were considered in sulphite practice. Wood used must be uniform in size, quality and preparation for economical digester operation. Digesters must be properly lagged, otherwise a large preventable heat loss will occur. The successful operation of the soda process hinges on this material—i.e., on soda itself. Losses that must be held down are in the lime mud (where a loss as low as 2 per cent may be obtained by careful practice) in the black ash waste, in the burning of black ash, in washing the black stock (unwashed pulp from digesters) and in leaky pipes, valves, etc. The amount of soda that may be lost in washing the blackstock will not be allowed to exceed 1.5 per cent in good practice. A fiber loss of close to 15 per cent in cooking such a wood as poplar seems unavoidable in obtaining good grades of pulp.

B. T. McBain, of the Nekoosa Edwards Paper Co., who has made a careful study of waste at all stages of fabrication from woodlot to packing room, presented a paper covering briefly the entire industry. Every piece of apparatus used must be watched and frequently checked up for performance; by checking heat, power and raw material losses, profit is derived from waste. Pumps, piping, screens, save-alls, beaters—all must function efficiently if the sewer and ventilators are not to carry off valuable materials. Care in looking after details will make possible elimination of costly leaks.

Successful coloring of paper requires the prevention of mottled fiber, the use of uniform pulp and the cutting down of foaming. A special problem arises in preventing a two-sided effect. Mottled fiber can be prevented by proper control of beater furnish and of temperatures of furnish and dyestuff when brought together. Slow-cook sulphite pulp tends to take a much deeper shade than quick-cook pulp. Great variation in shade results when successive cooks are colored with same dye. Acid dyes cause foaming very frequently. Furnish which gives foam troubles often yields to treatment by alum, which leaves it slightly acidic in reaction. Two-sidedness may be reduced by beating stock as free as possible, by use of dyestuff having maximum affinity for the stock, and by seeking to combine the dye with the fiber rather than with the filler.

What does the paper industry need? Which are the weak links in its organization? What is the future to bring for it? Hugh P. Baker, executive secretary of the American Paper and Pulp Association, maintains that the industry in the United States must watch its step. Canada will outdistance us in the near future in newsprint production. Our forests are going fast. Foreign competition must be met. We have too many mills for profitable production except in times of prosperity. To maintain healthy growth, waste must be eliminated, overproduction guarded against and new markets constantly developed.

Cost of De-inked Newspaper

Mills located near cities capable of furnishing large quantities of old newspaper can produce pulp from de-inked news cheaper than they can buy new groundwood, according to cost data collected by the U. S. Forest Products Laboratory, Madison, Wis. A saving of $15 a ton has been effected at one mill through the use of de-inked news instead of groundwood pulp. Such a saving would bring in a large return on the $10,000 investment needed to equip an ordinary 30-ton mill with the additional washing equipment and a warehouse large enough to hold a 3 months' supply of old newspapers, and it would make possible the profitable operation of some mills now finding it difficult to make both ends meet.

To make the most out of the de-inking process, it is absolutely necessary that the mill be independent of the periodical manipulating of the waste-paper market. For mills situated near the larger cities such a course is very simple. In fact, a large part of a mill's supply might be collected by its own force from the neighboring territory, thereby cutting out the profits of at least three middlemen.

In stabilizing the supply of waste papers the publishers can be of enormous assistance, since the supply is *directly dependent upon the amount of paper saved by* the average householder. With proper newspaper campaigns, such as were carried on during the war, the supply of waste newspapers could be doubled without much effort; and if with proper warehouse facilities the demand were stabilized, the supply would continue.

When old newspapers are worth $20 per ton, it costs about $38, with the necessary addition of sulphite pulp, to produce a ton of newsprint from the converted stock.

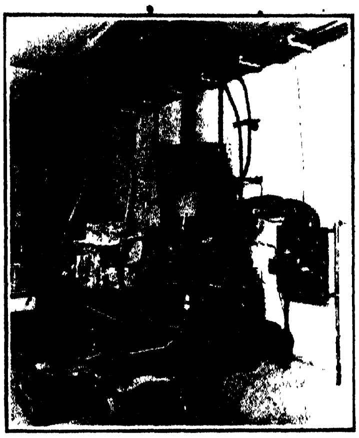
Materials and Accessories for Chemical Industries

High-Temperature Metal Melting

In the center of industrial New York there has recently been completed and placed in operation a new rare alloy melting and refining plant which is unique in many ways. The entire output of the plant is restricted to the melting of what may be termed "Higher-Temperature Metals." This includes melting of chromium, nickel-vanadium, chromium-nickel-tungsten, palladium alloys and pure tungsten, which necessitates temperatures in the melting zone of from 3,600 to 4,300 deg. F. The plant referred to is that of the Bario Metals Corporation, 147 Varick St., New York City. The entire plant includes the departments of management, chemical analysis, melting and machining. All of the operations in the melting and casting plant are with the electric furnace and oven. The equipment includes three Ryan high-temperature melting units, one Northrup high-frequency furnace, one electric core and mold baking oven.

Of particular interest is the Ryan furnace, as it presents a new departure in the field of electric metal melting. The units in the Bario plant have a holding capacity of 125 lb. per heat and are capable of melting and refining alloy mixtures in from 30 to 40 minutes from the time the cold charge is placed in the furnace. The furnace is of the graphite resistor type—that is, the heat is developed by the passage of current at particular voltages and specific quantities through a stationary graphite electrode. No difficulty has developed in obtaining furnace temperatures up to 4,300 deg. F. While temperatures higher than those stated are obtainable in the arc furnace, the difference is that in this furnace there is an equal diffusion of the heat over the entire bath; and the temperature gradient between the melting and refining point of the metals and the heat at the electrode can be kept very close, eliminating superheating, which is detrimental in alloy melting operation.



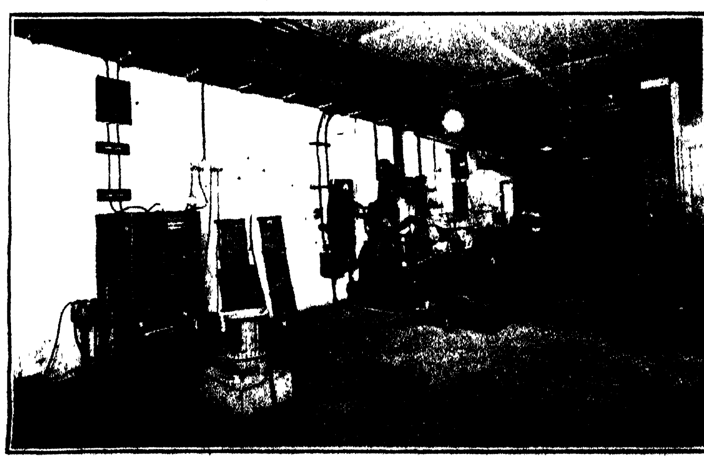
THE RYAN ELECTRIC FURNACE

As against this close temperature gradient, in the arc melting-furnace the heat is developed within very small areas at very much higher temperatures, as a result of which even distribution does not take place. This, of course, is not a detrimental factor in the melting of ordinary steel or even commercial alloy steels, but is particularly objectionable in the handling of rare alloys such as referred to because of the wide difference in the melting points during their amalgamation or melting, which if they are superheated causes considerable loss through oxidation. With reference to metallurgical operations, the furnace has sufficient door area and clearance to carry on any necessary slagging or charging operations.

The furnace is adapted for the melting of higher-temperature metals such as those named, and the manufacturers and developers of the furnace, F. J. Ryan & Co., Wesley Building, Philadelphia, do not believe that units over 500-lb. holding capacity will become practical owing to the restriction in size and length of electrodes and their placement throughout the furnace. However, in capacities from 50 lb. up to 500 lb. the arrangement and operation are extremely simple and present no new difficulties over present electric furnace practice.

The arrangement is, briefly, the connection of the furnace unit through the ends of the electrodes, which are in contact with water boxes attached to busbars running back to the transformer set directly in back of the furnace with tap arrangements connected with a radial type switch, by which a wide range of temperature control is secured. The furnace is lined with standard magnesite brick both in roof and hearth, and is of the stationary or nose tilt type, allowing for pouring directly from furnace into molds.

A novel arrangement of the fur-



ELECTRIC FURNACES IN PLANT OF BARIO METAL CORPORATION

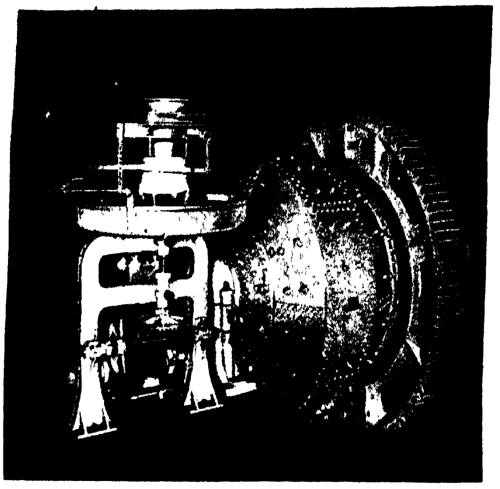
nace has been werked out to allow for maximum production. With each transformer setting there has been supplied two furnaces, each unit being set upon a truck. After the heat has been completed, by the loosening of two bolts the bus connections are disconnected, the furnace is moved from in front of the transformer, and a new furnace previously charged is moved in its place. The entire operation takes place within 5 minutes. This allows for maximum production in relation to horsepower connected load.

It is quite universal practice for power companies to charge for a connected load notwithstanding the percentage of producton in relation to the connected load. Therefore it is of advantage to the customer to be able to work his plant to the maximum point of that connected load, which is not possible where individual units are in operation a specified time and then shut down during pouring or casting periods. It is claimed by the manufacturers that the consumption of electrode and power is not in excess of that which now exists in the best electric melting practice.

Conical Mill Feed

The Hardinge Co., of New York City, has recently developed a new style of feeder for the Hardinge conical mill, which is applicable to both fairly fine and coarse materials. It is known as the table and screw feeder, and takes the place of the old style conical or drum feeder which was in use for so many years.

The feeder is capable of many times the capacity of the old style, as it actually forces the material into the mill. An arrangement of sealing ring is so designed that there is no back spill. There is also a device for taking care of any material which tends to work back of the feeder and cause wear. This method takes the material automatically and drops it into the upper part of the barrel in which the screw operates. The table is designed so that the feed may be regulated while the mill is operating. The table may also be stopped, or the feed cut off above the table while the mill is turning. This feeder has already had a number of successful applications. The cut shows one of the these feeders applied to a 7-ft. Hardinge mill for grinding cement clinker.



HARDINGE MILL FEEDER

Container Car Tanks

In many industries there is a distinct problem to be met in shipping various liquids by rail. The difficulty may be caused by corrosive action of the liquid on a metal container, or the liquid may be contaminated unless special containers or special precautions are taken. This difficulty has been solved in the past by using such containers as carboys or special cans or drums which were not subject to corrosion and could be easily cleaned. This solution of the problem did not, however, enable the shipper to realize the economy of bulk shipment. A new container which does offer this advantage has recently been placed on the market by the Pfaudler Co., of Rochester, N. Y. Developed primarily to solve the milk shipment problem, the equipment is also applicable for such fluids as light chemicals and oils.

It consists of a series of compartments, usually nine in number, which run transversely to the car. Each container houses a glass-lined tank, effectually insulated with cork, which is located between the double walls of the compartment. The containers are equipped with eyes or hooks at each top outside corner for handling by crane or hoist. The sides of the car are spaced to suit the width of the container, ½ in. clearance being allowed on each side. The glass-lined tank in the interior of the container compartment has a manhole for entrance of the liquid. Above this in the container shell (which is a metal and wood rectangular box) is a hatch provided with a lock. The outlet from the bottom of the tank is located opposite a small port in the container shell which can be closed and locked.

The containers are placed side by side in a specially designed car with low sides which come just above the ports in the container shells. This car is fitted with all the appliances needed to make it interchangeable with any standard railroad car. The capacity of the individual container is 600 gal. and of the loaded car 5,400 gal.

The makers of this car claim several advantages among which we mention that it eliminates handling of the cans, carboys or drums; it eliminates much waste time for unloading or loading box cars; it eliminates checking and rechecking at terminals; it makes sampling easier; and it lessens depreciation charges.

Catalogs Received

LEBANON BOILER WORKS, Lebanon, Pa.—Bulletin 23-A—A new bulletin describing the Lebanon line of return tubular boilers.

SOUTHWESTERN CONDENSER CO., Los Angeles, Calif.—Bulletin D-6. A new bulletin describing the Southwestern gasoline condenser and its application.

CONVEYORS CORPORATION OF AMERICA, Chicago, Ill.—Leaflet describing the "American" air-tight door for use in connection with boilers, coke ovens, oil stills, driers, retorts and various types of industrial furnaces.

LACLEDE-CHRISTY CO., St. Louis, Mo.—Bulletin dated April, 1923, describing various uses of Laclede-Christy firebrick.

DENVER FIRE CLAY CO., Denver, Colo.—Folder describing the different uses of the Hi-Fire bond, a cement for refractories.

DRIVER-HARRIS CO., Harrison, N. J.—Data Book R-23. A new book entitled "Alloys for Electrical Resistance," giving data in connection with various alloys used for heating elements in electric heaters of all kinds.

DETROIT RANGE BOILER & STEEL BARREL CO., Detroit, Mich.—May, 1923, bulletin on the metal barrel manufactured by this company.

ADAM HILGER, LTD., London, England—Catalog describing Professor Coker's apparatus for determining the distribution of stress in structural and machine members. Bulletin describing the Low-Hilger audiometer, an instrument designed to record the variations in pressure caused by sound waves.

F. J. STOKES MACHINE CO., Philadelphia, Pa.—Catalog 23. A new catalog on the well-known Stokes line of pharmaceutical and chemical machinery and apparatus.

ROLLER-SMITH CO., Bethlehem, Pa.—Bulletin 30. A descriptive bulletin on the Roller-Smith type of ammeter for three-phase a.c. circuit.

STEERE ENGINEERING CO., Detroit, Mich.—Pamphlet 243. A pamphlet on the Steere bellows type expansion drawing. Pamphlet 247, on the Steere system of backrun gas.

AUDUBON WIRE CLOTH CO., Audubon, N. J.—Folder on this company's new line of fine and extra fine brass cloth running up to 350 mesh.

Testing of Glue and Gelatin Gels

To the Editor of Chem. & Met.:

SIR—In a recent article (*Chem. & Met.*, vol. 28, p. 55) W. D. Richardson described the Bloom gelometer as adopted by the National Association of Glue and Gelatin Manufacturers.

During the course of work on the hydrolysis of collagen to gelatin a reliable method of jelly testing has been required by the writer. An adaptation of the gelometer devised by E. S. Smith (U. S. Pat. 911,277 of 1909) and modified by Hulbert and later by Low has proved of value.

In the original tester and in previous modifications, a rubber membrane, fastened over the end of an inverted thistle tube, was placed over a jelly surface and air pressure applied just sufficient to force a definite volume of water into the thistle tube.

The greatest source of weakness in this design is the uncertainty involved in bringing the gel surface flush with the membrane and always to the same point. Fig. 1 shows an assembled gelometer as modified by the writer. The inverted thistle tube has been replaced by a machined brass head (Fig. 2), in which a thin unstretched rubber membrane is mounted by means of a ground bevel, flush with the flat lower surface of a ring or collar which surrounds it.

In operating, the platform 1 is forced up against the tester-head 3, leveling the membrane. The water level is then adjusted in the pipette 4 to reach the upper mark by means of stopcock S_1.

Then with stopcock S_2 open and S_1 closed a jelly is placed on the platform 1 and raised until its surface is flush with the lower surface of the tester-head. The meniscus will not rise again to the upper mark in the pipette, since the jelly surface will be slightly depressed by the slight pressure of a water column in the pipette.

Stopcock S_2 is then closed, S_4 is opened and pressure is applied by pumping the bulb 10. The oscillations of this pressure application are minimized by the capillary 8 and the reservoir 7. When the water level in the pipette 4 has been forced to the lower mark, indicating 5 cc., S_4 is closed and the pressure is read on the scale 6. From this pressure is subtracted that required to force the water into the membrane when no gel surface is beneath it and a small correction is added for a depression of the mercury surface in the large arm of the manometer.

Two hundred cc. of 10 per cent solutions of the glues was used in crystallizing dishes of uniform size, which are 100 mm. in diameter by 40 mm. deep, and readily obtainable. The complete

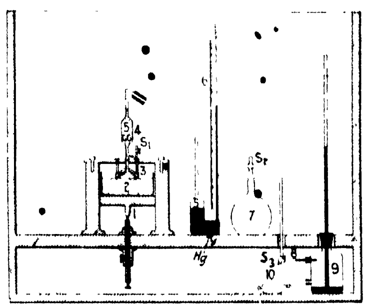

FIG. 1—NEW TYPE OF GELOMETER

gelometer was mounted in an air-bath kept in a refrigerated room and controlled thermostatically at 10 deg. C. to 0.2 deg.

Check determinations on a single gel after standing for 12 hours were concordant to within 2 per cent, while different gel samples of the same glue were found to check well within 10 per cent and generally to within 5 per cent. Due to ease and speed of manipulation, the device is applicable to routine tests.

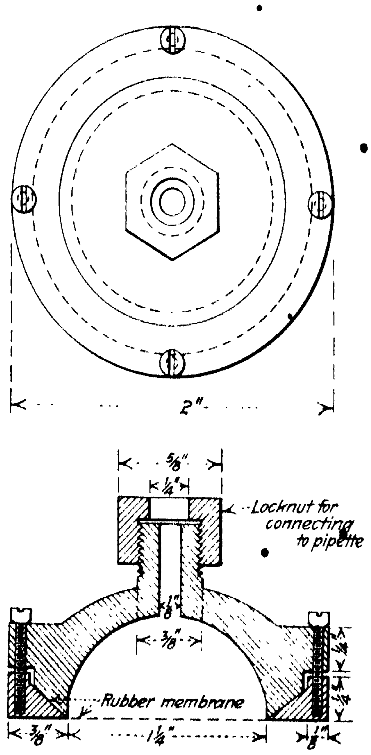

FIG. 2—MACHINED BRASS HEAD FOR GELOMETER

Bacchus Redivivus

To the Editor of Chem. & Met.:

SIR—From various circulars which reach us from our friends across the water, a valiant effort is being made to free us from the exactions of the peripatetic bootlegger. From a recent one:

> Something about
> Regenerated Beverages
>
> IT WILL not happen often that an offer of such solidity reaches you. Perhaps it is a chance that never comes again. Therefore, decide yourself.
>
> Here's your opportunity!
>
> What I am offering is no mixture of chemicals or other ingredients dangerous to health or one of the nowadays manifoldly offered powders, but a
>
> **dry substance**
>
> without a trace of alcohol, gained by concentration of guaranteed pure, natural alcoholic, original beverages. From this dry substance—by means of my formulas, which are so simple that a boy of 14 years can handle them—you can
>
> **regenerate the original beverage**
>
> guaranteed with all its primary characteristics such as bouquet, alcoholic content, etc.,
>
> **without being compelled to add even only one drop of alcohol.**
>
> The shipment is of course made immediately in an absolutely discreet way; material and formulas being sent separately.

So for one dollar (American currency, it is insisted), or 70,000 marks more or less, a package may be had from which 2½ gal. of tokay can be made. Or if your gullet prefers Münchener, merely say so, and a corresponding package will be received.

Possibly, Mr. Editor, you can name the branch of chemistry which developed this wonderful process. I nominate the originator to honorary membership in the Institute of Eye, Nose, and Throat Chemists. Will some one second it?

JAMES J. CURRAN.

Hartford, Conn.

What's Behind the Stock Dividend?

To the Editor of Chem. & Met.:

SIR—Your editorial in the Jan. 17 number, "What's Behind the Stock Dividend?" gleams forth from the mass of blatherskite amenities on this subject like a light amid the darkness. You bring out clearly that the injustice of the present non-taxability of stock dividends lies solely in the different treatment accorded to the earnings of enterprises not in the corporate form. It would be interesting to see a skilled protagonist of the corporation defend this discrimination. The writer is not such a one, but he would suggest that matters are evened up "if and when" the shareholder sells or transfers his

stock. You appear to regard this as a comparatively remote contingency. But it is at most no more remote than the demise of the stockholder, when his estate pays, and usually, too, pays in higher brackets of the income tax than does the accumulator of the same profits in the non-corporate form of business?

If the stockholder desires to cash in on the fruits of a wise and fortunate investment, the prospect of this big slice that the government takes from his "profits" often deters him from doing so, even thereby to his own disadvantage. This is foolish, I admit. But it is human. There is no doubt that this phase of the income tax affects the judicious manipulation of property.

Admitting, however, that fairness demands some such adjustment as you mention—namely, a lower rate on partnership profits passed to surplus, with the implied "penalizing" of wages—is there anything very immoral in stimulating thrift as against expenditure? Would not such a scheme have something of the advantages of a sales tax?

Right or wrong, however, to convince the public, as you say, is the dilemma.

CHARLES VAN BRUNT.

Schenectady, N. Y.

Review of Recent Patents

Developments in the Equipment Field

Rubber-Lined Acid-Proof Containers That Are Free From Blisters

ONE of the principal troubles with rubber-lined containers has been the difficulty in pressing the rubber lining onto the base material. This has been overcome largely by using closed molds, but it can also be accomplished by the method described in this patent (1,454,687, J. E Perrault, assigned to the Hood Rubber Co., Watertown, Mass., issued May 15, 1923). The author uses a mandrel or core of a shape conforming with that of the desired article which is slightly tapered in construction toward the bottom end. Around this are placed the rolls of unvulcanized rubber for lining and then a layer of fibrous material or cloth. The presser is then inserted into the container to be rubber lined, and vulcanization is carried out in what is commonly known as an open heat. Experience shows that blisters occur only on the bottom and on the sides near the bottom, hence the presser member needs only to cover these parts of the vessel.

Burning Sulphur

It has been the experience in industrial work that much of the crude sulphur which comes from the Gulf States is not free burning. This means that

American Patents Issued May 29, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met.* readers. They will be studied later by *Chem & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,456,504—Electrode Supporting Device. W. G Houskeeper, New York, N Y., assignor to Western Electric Co.

1,456,523—Method of and Apparatus for Treating Metals. R F Trimble, Elizabeth, N. J., assignor to Western Electric Co.

1,456,540—Regenerated Cellulose Material and Process of Making Same. N E Ditman, New York.

1,456,570—Method of Operation Employed in Extracting Liquid Vapor from a Gaseous Carrier. C C. Reed, Clarksburg, W. Va., assignor to Hope Construction & Refining Co., Pittsburgh, Pa.

1,456,590—Process of Making Halogenated Products. R E Eldred, New York, assignor, by mesne assignments, to Carbide & Carbon Chemicals Corp., New York.

1,456,592—Automatically Acting Lixiviation Apparatus. G. Haglund, Falun, Sweden.

1,456,594—Process of Making Sodium-Silico Fluoride. H Howard, Cleveland, Ohio, assignor to Grasselli Chemical Co., Cleveland.

1,456,615—Purifying Solutions of Iron and Recovering Metals From Such Solutions. D. Belcher, Boston, and F. A. Eustis, Milton, Mass., assignors of one-half to Charles Page Perin, New York, and one-half to said Eustis.

1,456,702—Process of Making Aldehyde Ammonia. H. W Matheson, Montreal, Que., Canada, assignor to Shawinigan Laboratories, Ltd., Montreal.

1,456,737—Centrifugal Separating Means. R. E. Lapham, Oakland, Calif.

1,456,781—Process of Recovering Cellulose Acetate From Solutions Thereof. J. M. Kessler, West Orange, and V. B. Sease, Newark, N. J., assignors to E. I. du Pont de Nemours & Co., Wilmington.

1,456,782—Cellulose-Ester Composition. J. M. Kessler, West Orange, N. J., assignor to E I. du Pont de Nemours & Co.

1,456,798—Process for the Extraction of Lead From Sulphide Ores. W H Hannay, Trail, B C., Canada, assignor to Consolidated Mining & Smelting Co of Canada, Ltd., Montreal.

1,456,809—Process for Treating Wood. G. F Lyon, Paris, France.

1,456,820—Conveyance of Highly Flammable Liquids. J. Muchka, Vienna, Austria.

1,456,834—Process for the Commercial Preparation of Potassium Phosphate. W H R and W. Hazen, Washington D C.

1,456,848—Process for Purifying Anthracene Press Cake. H. D. Gibbs, San Francisco, Calif., dedicated, by mesne assignment, to the people of the United States.

1,456,850—Process for Preparing a Concentrated Fertilizer. W. Hazen and W. H. Ross, Washington, D C.

1,456,855—Method of Joining Metals. T Midgley, Jr., Dayton, Ohio, assignor by mesne assignments, to General Motors Research Corp., Dayton.

1,456,871—Method of and Apparatus for Concentrating Liquids. I. Hechenbleikner and T C Oliver, Charlotte, N C., assignors to Chemical Construction Co., New York.

1,456,891—Electric Furnace Resistor. G M Little, Pittsburgh, Pa., assignor to Westinghouse Electric & Manufacturing Co.

1,456,892—Protected Electrode for Electric Furnaces. G. M. Little, Pittsburgh, Pa., assignor to Westinghouse Electric & Manufacturing Co.

1,456,893—Electric-Furnace Wall Construction. G M. Little, Pittsburgh, Pa., assignor to Westinghouse Electric & Manufacturing Co.

1,456,916—Process of Making Chlorhydrins. G. O. Curme, Jr., Clendenin, W Va., and C O Young, Elmhurst, N. Y., assignors to Carbide & Carbon Chemicals Corp., New York.

1,456,934—Method and Apparatus for Separating Materials. J. A. Rice, San Francisco, Calif.

1,456,949—Process of Purifying Natural Barium Sulphate. A. I. A. Teillard, Paris, France.

1,456,953—Separation of Natural Gas and Distillation Gases Into Gasoline and Other Constituents. A. von Groeling, New York, assignor to National Refining Corp., Inc., New York.

1,456,959—Process of Making Chlorhydrins. C. O. Young, Elmhurst, N. Y., assignor to Carbide & Carbon Chemicals Corp., New York.

1,456,969—Process for the Manufacture of Aromatic Amino Compounds. Oliver W Brown and C O. Henke, Bloomington, Ind.

1,457,030—Method of Treating Sludge Acids and Separated Sludge Acids. I Hechenbleikner and F J Bartholomew, Charlotte, N C., assignors to Chemical Construction Co., New York.

1,457,068—Process of Refining Hydrocarbon Oils. H. M. Lasher, Kansas City, Kan., assignor to Kansas City Gasoline Co.

1,457,072—Process for Refining Vegetable Oils. C H. Hapgood, Nutley, and G F. Mayno, East Orange, N J., assignors to De Laval Separator Co., New York.

1,457,084—Pulverizing Apparatus. W L McLaughlin, Decatur, Ill.

1,457,087—Method and Apparatus for Cooling and Cleaning Air. J. J. Preble, Waltham, and L H. Parker, Boston Mass., assignors to Spray Engineering Co., Boston, Mass.

1,457,110—Air Separator. R M. Gay, Hanover, N. J.

1,457,114—Azo Dyestuffs and Process of Making Same. A. L. Laska and A Zitscher, Offenbach-on-the-Main, Germany, assignors to the corporation Chemische Fabrik Griesheim-Elektron, Frankfort-on-the-Main.

1,457,131—Cellulose Acetate. J. O Zdanowich, London, England.

1,457,164—Method and Apparatus for Manufacturing Sulphuric Acid. T. R Harney, Short Hills, N J., assignor to New Process Acid Co., Inc., New York.

1,457,217—Apparatus for Applying Paraffin to Soap Cakes. G A. Dostal, New York, assignor to Pictorial Soap Manufacturing Corp., New York.

1,457,235—Azo Dyestuffs. R. Stüsser, Dentz, Germany, assignor to Farbenfabrike vorm Friedr. Bayer & Co., Leverkusen, near Cologne-on-the-Rhine, Germany.

1,457,279—Liquid-Weighing Device. W. G Finch, Grand Rapids, and Leon R. Finch, Ionia, Mich.

1,457,288—Bronze Alloy and Process for Its Production. P. Ostendorf, Berndorf, Austria.

1,457,289—Copper and Zinc Alloy. P. Ostendorf, Berndorf, Austria.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

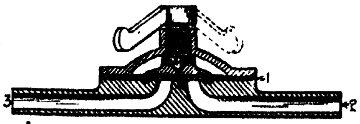
when ignited it is apt to go out. The reason for this is the fact that it contains small quantities of oil, and this oil spreads during the burning as a carbonaceous film, resembling asphalt in its consistency, over the surface. Eventually this extinguishes the sulphur flame, although the sulphur is only partly consumed. Traces of oil amounting to only 0.1 or 0.2 per cent are sufficient to render the sulphur non-free-burning. Harold S. Davis has patented (1,455,281, assigned to the Texas Gulf Sulphur Co., issued May 15, 1923) a method of making such sulphur free-burning. This consists essentially of mixing with the sulphur such substances as magnesia, asbestos and certain types of porous brick, and, to a lesser degree, magnesium carbonate, infusorial earth, fullers earth. These materials seem to act as a wick for the melted sulphur. The fibrous structure of some of the materials greatly aids in this action. They are also poor heat conductors, and therefore the heat generated in the burning surface is not conducted away rapidly enough to reduce the temperature below the ignition point.

This principle may be conveniently applied to both the cascade and the rotary burner, by lining the trays of the cascade burner and the drum of the rotary burner with asbestos or magnesia brick.

It is interesting to note that C. H. Weiskopf has patented (1,454,255, assigned to International Precipitation Co., issued May 8, 1923) an improved method for removing the precipitated material from the electrodes of an electric smoke precipitation apparatus. In such apparatus, the electrodes are of two kinds, so-called discharge and collecting electrodes. According to this new patent, the collecting electrodes are hung in such a manner that they may be shaken or jarred either by a balanced mechanism or by a small hammer. This dislodges the material from the electrodes and it falls down to a collecting hopper.

Valves for Corrosive Liquids

The main trouble with valves used in connection with corrosive liquids is, first, that the parts are rather difficult to replace and second, they are not inexpensive. These are the underlying principles in a patent (1,450,078, assigned one-half to T. Krug, issued March 17, 1923), issued to C. F. Hannz



of Buffalo. The accompanying diagram illustrates the construction and principle of operation. Liquid flow is shut off by depressing the flexible diaphragm 1, which is clamped over the two outlets 2 and 3. By releasing the pressor foot a shallow pocket is formed through which liquid may flow.

Tube Mill for Niter Cake

Everyone who has attempted to grind niter cake in a tube or ball mill realizes the very great trouble which arises from the caking of the product. This can be overcome, according to E. C. Soper, of Chattanooga, Tenn. (Pat. 1,454,491, May 8, 1923) by drawing a current of air through the tube mill to remove the water vapor and other gases and to prevent them from depositing on the surface of the mill and forming an undesirable cake. The apparatus needs very little explanation. The tube mill is of ordinary construction, with two chambers containing different sized balls. However, at the discharge end of the mill is an airtight chamber with two outlets. The solid material is discharged through a drop valve, and the gases and water vapor are carried up to a dust collector through a flue by the updraft created by air pressure.

Substantial Developments Heralded in Paper Industries

Bleaching, Deodorizing of Sulphate Pulp, Preparation of Lignin Pulp and Refinements in Use of Converted Fiber Attract Attention

THE BLEACHING of chemical pulp is an art only partly developed. As carried out in most practice today it is slow, expensive and difficult. Hence when such an engineer as R. B. Wolf patents a new improvement, the chances are that a fresh step has been made in progress. His present invention (1,454,610, issued May 8) embraces a bleaching tank of unusual design, preferably shaped like the frustum of a cone. This prevents the clinging of stock, which is circulated by means of a worm elevator in the center. A plow-paddle device revolves at the bottom to assist in working pulp toward the center. This form of apparatus makes possible the use of stock carrying 18 to 25 per cent pulp or even more. Ordinary bleaching tanks usually are limited to a concentration of 6 per cent of pulp. Working with this new vertical apparatus, time of bleaching is reduced, higher concentration of bleach may be used without injuring the fiber and the comparatively low temperature of 80 deg. F. may be employed to carry out the bleaching action.

Would Use Raw Material Completely

Not content with the loss of material involved in paper manufacture from straight cellulose, Carl Bache-Wiig has patented a process of treatment (1,455,471, issued May 15, 1923) which allows the utilization of lignin as well. Straw, cornstalks, wood or bagasse may be used. The material is first treated with 1 to 3 per cent sodium chloride at 70 to 110 deg. C. for from 12 to 72 hours. This procedure produces a greatly softened fiber. The successive treatment is a cook with a bisulphite liquor. By this process pulp suitable for a good newsprint may be obtained, according to the claims of the inventor.

Pulp Screen for Converted Stock

Hardly a month goes by without a new patent on a fresh wrinkle in paper stock treatment. F. P. Miller proposes to take unnecessary load off beaters by routing part of the digested stock directly to the paper machine and part only to the beaters. (1,455,594, issued May 15, 1923.) The stock is first digested and reduced in the usual manner, is then discharged onto a pile; the pile is reduced by a jet of water under pressure and the suspended stock conveyed to a screen. Here the coarse particles are separated from the fine; the fine material is then allowed to flow through a channel in which any heavy foreign material will collect. In this way the fine material is separated from the coarse, the latter being routed to the beaters, the former to the stuff chest.

To Kill the Odor of Sulphate Pulp

The odor of sulphate pulp has long characterized this process of manufacture. The odor is presumably due to the presence of mercaptans, higher sulphides or sulphur-lignin compounds. G. A. Richter, of the Brown Co., Berlin, N. H., has recently patented a method of treatment of sulphate pulp to remove its odor. (1,454,339, issued May 8, assigned the Brown Co.) The process consists in treating the wet pulp in a beater or washer with an oxidizing agent such as calcium hypochlorite at a concentration sufficiently low to prevent a bleaching action. In the method described approximately 2 per cent of hypochlorite is added on the basis of pulp weight. The reaction may be carried out simultaneously with the beating.

New Publications

THE NATIONAL RESEARCH COUNCIL has recently issued a Colloid Bibliography in mimeographed form. The author, Dr. Harry N. Holmes of Oberlin College, chairman of the National Research Council committee on the chemistry of colloids, intends this edition to be preliminary to a more comprehensive one. Yet it is a book of 135 pages containing 1,800 references on 106 topics. All the references are classified and many are accompanied by brief comment as an aid in deciding on their relative importance. This book may be purchased from the National Research Council, 1701 Massachusetts Ave., Washington, D. C., at $1.

AN ECONOMIC AND COMMERCIAL REVIEW OF THE ARTIFICIAL SILK INDUSTRY OF CANADA. Processes, raw materials, cost, tariff and other factors affecting the Canadian industry are considered. An appendix includes a survey of the industry in some of the principal producing countries. Compiled by the Natural Resources Intelligence Service, Department of the Interior, Ottawa, Canada.

Important Articles in Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

CONTACT SULPHURIC ACID. H. Braidy. Continuation of a series of articles. This one discusses drying towers. *L'Industrie Chimique*, May, 1923, pp. 194-7.

PRODUCTION AND USE OF LAMPBLACK. Rex Furness. Discussion of carbon black from natural gas and a criticism of process efficiency. *Chemical Age* (London), May 19, 1923, pp. 532-4.

EFFICIENCY AND COST COMPARISON IN BONE CHAR AND DECOLORIZING CARBON REFINERIES. G. Avot. An argument in favor of decolorizing carbons. *International Sugar Journal*, April, 1923, pp. 196-9.

ECONOMIC USE OF PHOSPHATE DEPOSITS. W. H. Waggaman. A word of caution from a careful student. *American Fertilizer*, May 19, 1923, p. 39.

EXPLOSIONS IN AIR COMPRESSORS. J. A. Vaughan et al. An exhaustive study of operating conditions and accidents in South African mines and plants. *J. So. African Inst. of Engrs.*, April, 1923, pp. 171-209.

SOME PRACTICAL NOTES on Oil Pumping. G. W. E. Gibson. Well illustrated article on design and present-day practice in operation. *J. Inst. of Petr. Technologists*, April, 1923, pp. 77-101.

FIRE HAZARDS AND FIRE EXTINCTION IN PETROLEUM INDUSTRY. Presidential address of Prof. J. S. S. Brame. *J. Inst. of Petr. Technologists*, April, 1923, pp. 113-128.

A METHOD FOR EXPRESSING THE VALUE OF MIXING AGENTS BETWEEN HYDROCARBONS AND 95 PER CENT ALCOHOL. W. R. Ormandy and E. C. Craven. *J. Inst. of Petr. Technologists*, April, 1923, pp. 129-133.

FREE SULPHUR IN MOTOR FUELS. W. R. Ormandy and E. C. Craven. *J. Inst. of Petr. Technologists*, April, 1923, pp. 133-139.

SUPER-DEODORIZATION AND THE NEUTRALIZATION AND BLEACHING OF VEGETABLE OILS UNDER VACUUM. Louis C. Whiton. An exposition of the Bataille process. *Cotton Oil Press*, June, 1923, pp. 30-33.

ORIFICE COEFFICIENTS—DATA AND RESULTS OF TESTS. J. M. Spitzglass. Tests to establish correct theory for orifice metering devices. *Mechanical Engineering*, June, 1923, pp. 342-48.

ACTION OF BACTERIA ON CELLULOSIC MATERIAL. A preliminary study of bacteria as affecting fermentation and decay. *Chemical Age* (London), May 12, 1923, pp. 510-511.

ACTION OF HEAT ON CHEMICAL PROPERTIES OF COTTON. J. Merritt Matthews. A general summary of the physical factors governing chemical changes in cellulose, with especial reference to heat. *Color Trade Journal*, June, 1923, pp. 255-258.

CLASSIFICATION AND DEFINITIONS OF PAPER. C. J. West. A comprehensive classification of different papers, with full definitions for use in manufacture and merchandizing. *Paper Trade Journal*, May 31, 1923, pp. 49-54.

THE MARKETING OF LEAD. Irwin H. Cornell. One of an important series of articles on the marketing of metals by sales executives. *Engineering and Mining Journal-Press*, June 2, 1923, pp. 967-70.

A NEW DEPOSIT OF HIGH-POTASH FELDSPAR IN ONTARIO. A. M. Campbell. An account of the new quarry in Lanark County. *Engineering and Mining Journal-Press*, June 2, 1923, pp. 979-80.

Men in the Profession

ALEXIS C. HOUGHTON has resigned as chief chemist of the Solvay Process and Semet-Solvay companies, Syracuse, N. Y., to take charge of the phenol plant of the Bakelite Co., New York City.

ERNST JOHANSEN has resigned his position as head of the research department of the Atlantic Refining Co., Philadelphia, to become chief chemist with the New England Oil Refining Co., Fall River, Mass.

CHARLES A. MAY, head of the Lamberton Works of the Maddock Pottery Co., Trenton, N. J., is recovering from a severe illness.

LEROY H. MINTON, general superintendent for the General Ceramics Co., Metuchen, N. J., has been elected vice-president of the local Chamber of Commerce.

DR. R. B. MOORE, retiring chief chemist of the Bureau of Mines, was guest of honor at a luncheon on May 29, which was attended by a large number of his associates at the bureau.

C. EDWARD MURRAY, JR., has been elected president and treasurer of the Murray Rubber Co., Trenton, N. J.

H. L. PRATT has been elected president of the Standard Oil Co. of New York, succeeding HENRY C. FOLGER, JR., who has been appointed chairman of the board of directors, a new office recently created. Mr. Pratt has been vice-president and will be succeeded in this office by CHARLES M. HIGGINS, formerly secretary. FREDERICK S. FALES has been elected secretary.

ERNST REINHARDT, ceramic engineer for the Chelsea China Co., New Cumberland, W. Va., has resigned to accept a similar position with the Hagar Potteries Co., Dundee, Ill.

H. R. SARGENT, formerly manager of the wiring supplies division of the Bridgeport Works of the General Electric Co., has been appointed managing engineer of this division under a development plan which will create several unit divisions at the Bridgeport factory.

L. I. SHAW, assistant chief chemist of the Bureau of Mines, delivered, on June 6, the dedication address at the new chemical building of the New York State School of Ceramics at Alfred University.

RICHARD STRATTON, manager of the Giant Powder Co., San Francisco, Calif., is on a visit to Eastern cities, including Wilmington, Del., where a conference has been held by company officials.

C. G. STUPP, formerly assistant chief chemist of the research department laboratory of The Barrett Co., New York City, and more recently with the National Aniline & Chemical Co., Buffalo, N. Y., has resigned to accept a position with Weiss & Downs, of New York City.

MALCOLM W. THOMPSON, secretary-treasurer of the Hall China Co., East Liverpool, Ohio, gave an interesting talk before the members of the local Rotary Club, May 29, on the subject of hotel chinaware.

W. M. WEIGEL, who has been working on non-metallics, particularly fillers, at the Tuscaloosa station of the Bureau of Mines, is to be transferred to the Washington office shortly as assistant to the chief chemist in charge of non-metallic matters. Mr. Weigel will take up his work in Washington some time before the first of July.

Obituary

WILLIAM M. BENNETT, vice-president of the Clinchfield Portland Cement Co., Kingsport, Tenn., died in that city on May 26, following an attack of acute indigestion. He was 56 years of age.

LUDOLPH OSCAR KOVEN, of L. O. Koven & Bro., Jersey City, N. J., died on May 17 in New York City.

CORNELIUS S. SWEETLAND, president of the Rumford Chemical Works, Providence, R. I., died at the Jane Brown Memorial Hospital in that city on May 30, in his seventy-eighth year. He was active in the organization up to the time of his death.

Calendar

AMERICAN CHEMICAL SOCIETY, fall meeting, Milwaukee, Wis., Sept. 10 to 14.

AMERICAN ELECTROCHEMICAL SOCIETY, forty-fourth meeting, Dayton, Ohio, Sept. 27 to 29 (dates provisional).

AMERICAN ELECTROPLATERS SOCIETY, eleventh annual meeting, Providence, R. I., July 2 to 5.

AMERICAN GAS ASSOCIATION, annual convention, Atlantic City, Oct. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, summer meeting, Wilmington, Del., June 20 to 23.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS, iron and steel exposition, Buffalo, N. Y., Sept. 24 to 28.

AMERICAN SOCIETY FOR TESTING MATERIALS, twenty-sixth annual meeting, Chalfonte-Haddon Hall Hotel, Atlantic City, June 25 to 30.

INSTITUTE OF MARGARIN MANUFACTURERS, fourth annual convention, Hotel Traymore, Atlantic City, June 14 and 15.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH), New York, Sept. 17-22.

NATIONAL FERTILIZER ASSOCIATION, thirtieth annual convention, White Sulphur Springs, W. Va., June 11 to 16.

NATIONAL LIME ASSOCIATION, fifth annual convention, Hotel Commodore, New York City, June 13 to 15.

SOCIETY FOR STEEL TREATING, Eastern sectional meeting, Bethlehem, Pa., June 14 and 15.

Industry and Trade

Current News and Market Developments

Summary of the Week

Revised alcohol regulations submitted to committee representing trade.

Government suit against Chemical Foundation begins at Wilmington, Del.

Federal Trade Commission starts hearing of case against naphtha soap products of Procter & Gamble.

Lower prices for tin have been followed by easier quotations for tin products.

Imported copper sulphate has been under selling pressure and sold at new lows for the movement.

Cottonseed oil strengthened on covering by shorts, following a rise in prices for cotton and lard.

Supreme Court holds that linseed companies violated Sherman act.

Importers will not be required to pay duty on merchandise lost while in government custody.

Weakness in chemical prices offset by rise in cottonseed oil and index number for the week shows gain.

Demand for arsenic and calcium arsenate remains slow and prices are tending downward.

Large silk dyeing companies in New Jersey merge into one of the largest establishments in the world.

Steadier seed markets checked the easier feeling in linseed oil market.

Prices for Chemicals Moving Downward

THE UPWARD SWING of prices for chemicals, which started last October, continued unbroken into April. A reaction which then set in was in evidence throughout May and gradual declines in various commodities brought about a lower average selling price.

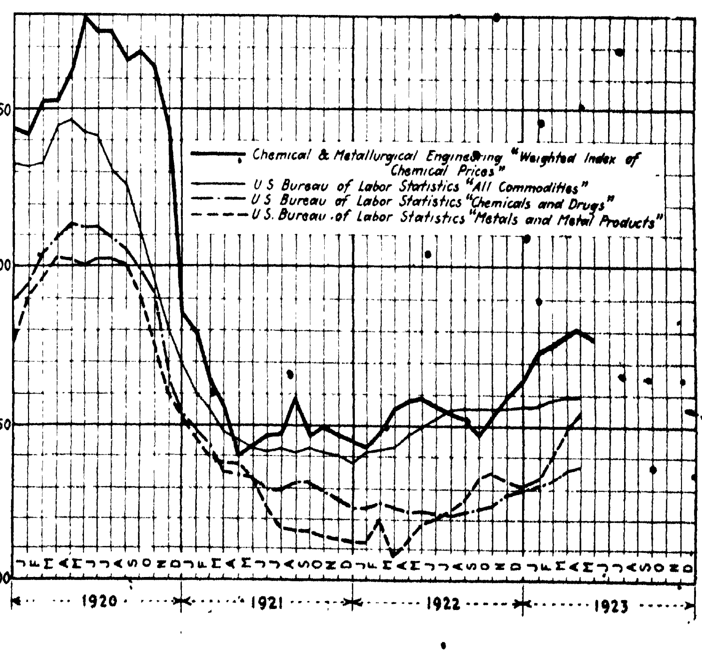
Chem. & Met.'s weighted index measures this decline in definite figures and reveals a high of 181.61 in April, as compared with 177.64 at the end of May. In other words, average prices for chemicals in April were more than 81 per cent higher than those that prevailed in 1913-14. While this percentage was decreased in the past month, the index number at the end of May shows a decline of less than 2¼ per cent from the high of the year.

To a very great extent, the steady rise in market values during the first 3 or 4 months of the year may be attributed to the unusually active condition of the various consuming industries and the correspondingly greater call for materials. Conversely, the softening of prices reflects a slowing up in general business activities and a less urgent call for supplies.

The influence of chemicals of foreign origin also has helped to depress values for different domestic selections. While consumers were in a position to take practically everything offered, importations were readily absorbed. When buying orders assumed smaller proportions, exporters in outside markets continued to ship heavily. As a consequence stocks began to pile up and holders began to offer price concessions as a stimulant to trading. This had the twofold effect of weakening confidence in values and of making buyers cautious in committing themselves on requirements for any period ahead.

In contrast to the depressing effect of selling pressure and slower consuming demand, the labor situation has been a steadying factor on values for chemicals. High labor costs are generally reported by domestic manufacturers and scarcity of labor also is given as a prime reason for the firm position held by certain chemicals. Uncertainty about the labor situation likewise casts its shadow about plans for future operations and undoubtedly this will be a price factor in the market for chemicals for some time to come.

The general level of wholesale prices as compiled by the Bureau of Labor is not yet available for the month of May. April figures of the bureau give the index number for "all commodities" as 159, which is a duplication of the figure for March, thus showing no change for the month. Chemicals and drugs made a slight gain, the number being 135 for March and 136 for April. Metals and metal products offer a comparison of 154 for April and 149 for March.



Trade Committee Will Pass on Revised Alcohol Regulations

Draft Now in Hands of Trade Alcohol Advisory Committee—Closer Co-operation Between Technical Users and Internal Revenue Department

THE draft of the revised Regulation 60 is in the hands of the Trade Alcohol Advisory Committee. It covers 250 typewritten pages. Copies will be sent to each member of the advisory committee for his criticism and suggestion. If need arises to correlate any of the changes suggested the advisory committee will be called together for that purpose.

The action of the Commissioner of Internal Revenue in turning over the draft of the regulation to the committee followed closely after the organization meeting of the committee. It is thought to indicate that he will do just what he has promised in co-operating closely with the legitimate producers and consumers of industrial alcohol. This is the first time since the enactment of the Volstead law that the technical industry has been called in formally.

Within 2 months after July 1 all holders of permits to withdraw beverage alcohol must renew them. For that reason every effort will be made to liberalize the regulation promptly so that it will not be so great a check on legitimate industry. One member of the advisory committee told Internal Revenue Commissioner Blair and Prohibition Commissioner Haynes that under existing regulations the cost of policing an alcohol plant equals the cost of fuel and adds a very large item to manufacturing costs. By adding this large item of cost to the long list of American products which make use of alcohol American goods are at great disadvantage in competing with the products of foreign manufacturers, who are spared all of that cost as well as others which the regulations are held to have heaped on trade alcohol.

The advisory committee at its initial meeting selected William M. Sailer as its chairman and H. E. Howe as its secretary. Mr. Sailer is the president of Sharp & Bohme and is the president of the American Drug Manufacturers' Association. Mr. Howe is editor of *Industrial and Engineering Chemistry*, the publication of the American Chemical Society. R. M. Cain, of the Swan-Meyers Co. of Indianapolis and president of the American Pharmaceutical Manufacturers' Association, was added to the membership of the advisory committee.

To Make Chilean Nitrate Survey

H. Foster Bain, Director of the Bureau of Mines, to Undertake the Task

Before making any recommendations in connection with the study being made of nitrogen supply, the Department of Commerce recognizes that additional accurate knowledge must be had as to the situation in Chile as it affects the production and distribution of nitrate of soda. It is recognized that the gathering of this information is a delicate task. For that reason it has been decided to send on this mission H. Foster Bain, the director of the Bureau of Mines, who, in addition to being the head of the government agency which represents the mining industry, is a mining engineer and mineral technologist who has had wide experience abroad. He will be accompanied by Harry S. Mulliken, technical assistant to the director of the Bureau of Mines.

The opinion has been expressed that neither the Chilean Government nor the nitrate producers in that country would welcome an emissary from the United States Government when the avowed intention of the law under which the visit would be made is to devise means of arousing competition for one of their great resources. It is believed, however, that by sending a high federal official to Chile he will be able to secure the necessary information, because both the Chilean Government and the nitrate producers probably prefer giving actual facts to a person of unquestioned responsibility, who could be relied upon to make only proper and accurate use of the data, rather than have the Secretary of Commerce predicate his recommendations on exaggerations. If the accurate information is withheld, the only recourse would be to secure the data from other sources. Inaccuracies would be certain to result. As a consequence, a distorted picture of the Chilean monopoly probably would be painted. The Chileans must recognize that the United States is in a position to make itself self-supporting, ultimately, in the matter of nitrogen. The only hope of preventing drastic action looking to that end would be to demonstrate that the cost of such a course would be too great to justify it.

Reduction in Sulphur Tax

The Senate Committee on State Affairs of the Texas Legislature is arranging for a reduction in the tax on sulphur from 2½ to 2 per cent. A bill is also being drafted to have the latter tax of 2 per cent apply on other natural products, including turpentine, iron ore, carbon black, salt, lime, cement, fullers earth, lignite, quicksilver or cinnabar. The committee is also considering a tax of ½ of 1 per cent on all oil refinery products.

Definite Chemicals Needed in Food, Says Mendel

Prof. Lafayette B. Mendel, of Yale University, addressed the members of the California Section of the American Chemical Society at San Francisco on June 1, the subject being "What Constitutes a Food." Dr. Mendel emphasized the importance of paying attention to the "little things" in diet. He described the regional incidence to goiter, and the need for minute amounts of iodine in food. The normal human being needed calcium, but most of the typical foods contain none. Vitamins, likewise, are essential; when omitted, a rapid decline in health takes place, in some cases due to an aversion to what formerly was considered a balanced diet, which aversion disappears after vitamins have been administered, even unknown to the patient. Professor Mendel deprecated generalizations in regard to the value of apparently similar foods and to the effect of heat on vitamins. All fats and oils were not of the same food value per unit of weight; in this connection the vitamin content of cod liver oil was emphasized. Cooking or heating does not necessarily destroy the vitamin in foods.

Swedish Industry Getting on Its Feet

In Sweden, according to a Reuter dispatch, the situation in the engineering industry has further improved and is, in fact, better than at any time since the middle of 1921. This is partly due to German competition having been checked by the occupation of the Ruhr. On the other hand, the Ruhr conflict and the Swedish labor dispute have made raw materials dearer and scarcer. The outlook is especially bright in paper industrial development. Orders for match-making machinery have fallen off. Mining prospects are good if they may be judged by demands for mining equipment.

Record Output of German Potash in 1922

The annual reports of the three producing potash companies of Germany—the Salzdetfurth, Aschersleben and Westeredeln—were made public on June 1 and revealed that production of potash in Germany in 1922 was the largest in the history of the trade. The total potash marketed was 12,955,433 double centners, as compared with 11,103,694 in 1913, the previous record year, and 9,211,814 in 1921. (A centner is slightly more than 110 lb.)

Foreign buyers took 25.6 per cent of last year's production, as against 16.6 per cent in 1921 and 45.6 in 1913. The American market is reported as particularly favorable.

The dividends declared by the three concerns were: Salzdetfurth, 350 per cent, as compared with 24 per cent in 1921; Westeredeln, 200 per cent, as compared with 20 per cent in 1921; Aschersleben, 150 per cent, as compared with 16.

Unfair Sales Methods Furnish Charge in Naptha Soap Dispute

Procter & Gamble Products Questioned by Federal Trade Commission—Company Doubts Government's Right to Specify Use of Certain Ingredients

CENTERED at the Engineering Club, New York City, at time of going to press, an interesting flurry exists in the soap industry. The Federal Trade Commission, following up the complaints of an unnamed party, charges Procter & Gamble with unfair sales methods. P. & G. White Naptha Soap and "Star Naptha Washing Powder" are furnishing the chief bones of contention. Although the identity of the complainant has not been revealed, evidence appearing in cross-examination of the witnesses indicates that the samples for analysis upon which the dispute rests were furnished by Fels & Co., of Philadelphia.

Examiner John W. Addison of the commission is hearing the case. Frank T. Dinsmore, counsel for Procter & Gamble, opposes W. C. Reeves, counsel for the commission. J. H. Bower, who has been in charge of soap chemistry for the Bureau of Standards since 1914, figures in the fray, as does Earl P. Stevenson, vice-president of the Arthur D. Little Co.

Naphtha Content Is Argued

Naphtha and sodium silicate are the ingredients about which the argument revolves. The complainant claims that there is an insufficient amount of distillate present in these products to be of use in enhancing the detergent value of the soap. Likewise in the instance of Procter & Gamble products that the amount of sodium silicate therein constitutes an adulteration in view of the advertisement of the respondents that only materials too good for ordinary laundry soap go into their products. Mr. Dinsmore contends that the government has no authority to fix the percentage of this ingredient or to say whether or not it is an adulterant in amounts therein present. Mr. Stevenson stated that while the use of silicate in amounts up to 10 per cent may contribute desirable characteristics to the soap, in excess of this amount it must be regarded as an adulterant. He said the chemical definition of soap is an alkali salt of fatty acid, and that sodium silicate is not soap, but in reply to further questions said he knew of only one soap which approached this definition very closely. That soap was not mentioned.

Whether or not the petroleum distillate used in P. & G. products may be classified as naphtha opened another question to dispute. The witness refused to admit that naphtha is a vague and variable term and defined naphtha as a light, volatile, flammable hydrocarbon which should have an initial boiling point ranging up to 300 deg. and an end point not in excess of 450 deg.

In speaking of the analysis of the P. & G. products made at the Arthur D. Little laboratories, Mr. Stevenson stated that it revealed the presence of only very small percentages of petroleum distillate which could not be classed as naphtha, and which, in his opinion, was not of sufficient quantity to enhance the cleansing power of value of these products. He also expressed the opinion that white laundry soap is not any better for washing purposes than yellow soap because of color.

Respondents' answer to the complaint claims that the amount of naphtha and silicate of soda used in their soap and washing powder do add to their efficiency.

For government experts in support of the testimony of the A. D. Little laboratories, Ivan M. Tull, general manager of the National Dyers and Cleaners Association, took the stand. R. F. Bacon, T. T. Gray and A. H. Gill have also given testimony. Other witnesses are still to be called.

Following the present hearing a postponement of the case until fall is expected when it will in all likelihood be reopened at Cincinnati for the purpose of hearing the defense of the respondents.

Manufacturing Chemists Hold Annual Election

Meeting at the Whitehall Club, New York, on June 6, the Manufacturing Chemists Association held its annual election. The annual report of the executive committee was also presented, covering the year's activities. These included work upon tariff, patent and waste disposal legislation, upon various phases of transportation and improvement of containers for chemical products.

The following officers were elected for the coming year: President, A. H. Hooker, Hooker Chemical Co.; vice-presidents, C. W. Miller, of the Davison company, and M. C. Whitaker, of the United States Industrial Alcohol Co.; treasurer, S. W. Wilder, Merrimac Chemical Co.; secretary, J. I. Tierney. The executive committee, headed by Chairman Henry Howard, Graselli Chemical Co., also includes the following six members: A. G. Rosengarten, Powers, Weightman, Rosengarten Co.; Lancaster Morgan, General Chemical Co.; H. H. Dow, Dow Chemical Co.; R. T. Baldwin, National Aniline & Chemical Co.; W. H. Bower, Henry Bower Chemical Manufacturing Co.; C. L. Reese, E. I. du Pont de Nemours & Co.

News Notes

The Beaver refining plant at Washington, Pa., burned on May 27. Only three gasoline tanks and a small office remained standing late in the morning. One hundred thousand gallons of gasoline had been burned and the damage was estimated at $225,000.

The University of West Virginia is planning to build a new chemistry building at Morgantown. The structure is to be four stories, with an extension of one story and basement.

The Alberta Clay Products Company has received orders for upwards of fifty carloads of clay products from two British Columbia points. Another large company is contemplating erecting a plant to utilize the clays of the district. The natural gas supply in that region is a valuable auxiliary to the clay product industry.

Western New York section elections of the American Chemical Society on May 29 were: chairman, G. P. Fuller, Niagara Falls; first vice-chairman, J. A. Handy, Buffalo; second vice-chairman, E. L. Koethen, Niagara Falls; secretary, R. W. Hess, Buffalo; treasurer, R. A. Nelson, La Salle; executive committee, M. J. Ahern, Buffalo; H. N. Gilbert, La Salle; J. R. MacMillan, Niagara Falls; councilors, C. G. Derick, Buffalo; Walter Wallace, Niagara Falls, A. M. Williamson, Niagara Falls.

The Mexican Petroleum Company is negotiating with the Davison Chemical Company for the silica gel process, according to a statement by an official of the company. Following this report the Mexican Petroleum Company declared at New York that it has been looking into the silica gel process of the Davison Chemical Company for about two years.

American Smelting & Refining Co. will close its tin smelter at Perth Amboy, N. J., July 1, owing to inability to get further supplies of Bolivian tin concentrates in competition with English tin smelters which are able to smelt at much lower cost because of cheaper labor and supplies. It is understood that the only other tin smelter still operating in the United States will close about July 31. All five smelters in the United States will then be down.

The twelve hour day in the steel industry is being widely condemned. Churches of all denominations are in accord with the views of the Federated American Engineering Societies. According to the report of the work periods committee of the latter society, profits need not suffer by the change from a twelve to an eight-hour day.

The Cottrell process is to be installed at the smelter of the Electrolytic Zinc Company of Australasia, Inc., Risdon, Tasmania. K. I. Marshall, of the Western Precipitation Company, has already sailed to do the work.

Washington News

Expansion of Chrome Ore Production in Rhodesia

In a report to the Department of Commerce, Consul C. I. Pisar of Cape Town says a feature of mineral production in Rhodesia during the later months of the year 1922 has been the expansion of the chrome-ore industry. The total production of chrome ore in 1921 was 50,188 tons, and in 1922 94,475 tons. The highest production for any single month was in November, 1922, when 24,814 tons were mined.

For some years past southern Rhodesia has been one of the principal chrome-ore producing countries in the world, and, as in the case of various other minerals, the demand occasioned by the European war resulted in a very marked increase in output. Between June, 1921, and May, 1922, the demand dropped to such an extent that practically all the mines in Rhodesia ceased producing. Since May, 1922, there has been a revival in the demand for chrome ore on a larger scale than ever.

The principal producers of chrome ore in Rhodesia are associated ventures styled "the Rhodesian Chrome Mines, Ltd., and the Rhodesian Metals Syndicate, Ltd. These companies hold claims in other parts of Rhodesia than the Selukwe district, where the principal deposits are located, and such is the variety of their deposits that they are able to supply almost any grade, both hard and "fines." The deposits are very extensive and mining costs are comparatively low. The present price of Rhodesian chrome ore (50 per cent) is from £5 to £6 per ton.

Albumen Containers Need Not Be Marked

Importers of egg albumen recently met and protested against a decision of customs appraisers officers to the effect that the immediate containers of albumen must be marked to show the country of origin. The importers decided to send a representative to Washington to protest against this ruling. After a conference with Assistant Secretary of the Treasury Moss, it was announced that the containers need not be marked. David Walker, who represented the importers, held that these containers were imported in an outside case which was the unit of sale, and that these cases went with the merchandise to the ultimate consumer.

Mr. Moss agreed that the importers were right in their contention that under the provisions of the 1922 act the actual containers of the albumen need not be marked, provided the outside case is properly labeled. A ruling to this effect, Mr. Walker said, will be handed down within the next few days.

Standardization Conference Dates Changed

Director George K. Burgess, of the Bureau of Standards, announces that several changes in date of conferences on standards have been necessary. The modified schedule for these conferences is as follows:

Preparation and unification of commodity standards, 10 a.m., June 11, conference room, Department of Commerce Building;

Conference on transverse fissures in rails, 9:30 a.m., June 15, room 30, South Building, Bureau of Standards;

Non-destructive testing of wire rope, 9:30 a.m., June 6, room 237, Industrial Building, Bureau of Standards;

Refractories used in steel industry, 10 a.m., June 18, room 704, Department of Commerce Building;

Standardization of paper, 10 a.m., June 19, Conference Room, East Building, Bureau of Standards;

Conference of tin plate manufacturers postponed to 9:30 a.m., Aug. 15, room 237, Industrial Building, Bureau of Standards.

Those desiring further information regarding the scope or progress of these conferences should address the Director Bureau of Standards, Washington, D. C.

Bureau Gas Chief to Direct California Research

Walter M. Berry, who has been chief of the gas engineering section of the Bureau of Standards, has resigned effective July 1 to become engineer in charge of research of the California Gas Research Council. The council is made up of representatives of California public utility companies interested in supply of manufactured gas and the utilization of it and natural gas. The work of the council will continue the research on gas utilization which has been in progress for several years. This has been carried on jointly by the utility companies and the California Railroad Commission. As a result of Mr. Berry's resignation, it is thought probable that the experimental studies of gas utilization at the bureau, which have been under his direction, will be transferred to the Chemical Division to be directed by E. R. Weaver.

Denatured Alcohol Formula

The Internal Revenue office of the Treasury Department has sent a notice to collectors, authorizing the use of specially denatured alcohol in the manufacture of bay rum and lotions for external use. The new denaturing process is called Formula No. 39-D and provides for the addition of 50 avoirdupois oz. of quinine sulphate and 1 gal. oil of bay N.F. to every 100 gal. of pure ethyl alcohol of not less than 190 deg. proof.

Netherland Chemical Trade in 1922

Chemical factories in the Netherlands, as a rule, did well during the year 1922. The export trade has increased materially in the past 2 years, with a considerable development of trade with the United States. The Dutch manufacturers also are finding it more nearly possible to supply their home market with many products that were formerly imported from other countries, this being the case especially with artificial fertilizers, which form an important item in the Netherlands. The manufacture of many varieties of drugs, formerly obtained mostly from Germany, is on the increase.

Turpentine and phosphate are the principal chemical products imported by the Netherlands from the United States. The following table shows the value of these and other important items imported from this country by the Netherlands in 1921 and 1922:

	1921	1922
Chilean nitrate	$105,916	$86,640
Phosphate	793,121	858,040
Caustic and other soda	47,996	96,900
Various chemical products	206,895	389,880
Dyes and colors	161,125	88,160
Turpentine	573,369	714,020

Delivered Weights to Govern Import Duties

Reports that importers would be granted an allowance in liquidating duties on imports where part of the goods were lost before passing into possession of the consignee have been confirmed. Hereafter duty will not be collected on merchandise which is lost while in government custody. Up to the present duty has been levied on the full shipments as indicated on the consular invoice. The collector's office in announcing the change stated: "The decision of the Customs Court is therefore controlling, and this office will modify its present practice and make due allowance, in liquidation, for all articles which the appraiser reports missing from the package under examination."

Italian Sulphur Production

Production from the sulphur mines of the Montecatini Co., near Rimini, Italy, amounts to about 40,000 tons a year. The last annual report of the company states that the 1923 output will be limited to this figure in order to enable Sicilian sulphur to find a market on the Italian mainland.

The Montecatini Co. has given up its interest in Sicilian sulphur companies and is interested at present only in the Gallitano Sulphur Mine and the Societa Solfifera Siciliana.

The 1922 annual report of this company states that the recent agreements between American producers and Sicilian sulphur consortiums can not improve the condition of the Sicilian sulphur industry, but that improvement in this industry can be obtained only by reducing the cost of production.

Government Reopens Suit Against Chemical Foundation

Preliminary Evidence Presented by Government and by Defence—Textile Alliance Cleared—Trial Likely to Be Long

THE suit of the government against the Chemical Foundation, Inc., is under way. The return of 4,500 patents seized and sold during the war by the Alien Party Custodian is being sought by the government. Judge H. M. Morris is presiding at the trial, which is being held at Wilmington, Del. Isador J. Kresel is chief counsel for the defence, while William D. Guthrie is also acting as counsel for the Foundation. Col. Henry W. Anderson, Assistant Attorney General, is pressing the case for the government.

Colonel Anderson endeavored to show that there had been some attempt on the part of chemical and dyestuff manufacturers in this country to combine. In connection with this he cited the formation of the American Dyes Institute, which has since been dissolved. He said, however:

Trial Not Under Sherman Law

"I want to make it quite clear that we are not here to try a monopoly case or a case under the Sherman anti-trust law in restraint of trade. I am avoiding in this case, and hope we can avoid throughout, any suggestion of international wrong. But I think it is pertinent to this case to show that there was a combination of bidders for the purchase of trust property. This is one of the elements to be considered in ascertaining the circumstances of the development of this combination and its heading up to the fact of getting control of these patents and bringing about a private sale thereof. This sale was brought about under terms which we will contend were ridiculous in the matter of consideration.

Colonel Anderson stated that those representing chemical interests, who were instrumental in bringing about the sale and who aided the alien property custodian in assembling information leading up to the sale of the patent, might, under the technical rulings of the law, be held guilty of a breach of trust in that they had induced officers of the United States government to bring about the sale of the patents.

Foundation Claims Justification

Kresel and Guthrie, in response to the government's charge, which occupied almost the entire first day of the trial, maintained that President Wilson and Mr. Polk favored the transaction, knowing all the facts; that the question of price was of secondary importance. Instead of being worth $100,000,000, as Attorney Anderson claimed, the actual value of the patents is, they claim, slight as far as workability is concerned. Actually less than 10 per cent of these have been used at all and of those used only a few have yielded profit. Kresel maintained that the books of the Foundation, which are open, prove that point. To return these patents to the government practically necessitates their return to Germany. such action, the Foundation counsel claims, would severely menace the American chemical industry, which is just now becoming thoroughly established.

Open to Reorganization

In reply to criticism of the Chemical Foundation made by counsel for the government, Mr. Kresel said the Foundation's managers were ready to have a complete reorganization, if necessary, in order to fully meet all objections that may justly be urged against its charter. It has administered its trust fairly, he added, issuing licenses to all persons applying for them for use in legitimate manufacturing purposes on fair and equal terms. It has scrupulously carried out the trust reposed in it. Its purpose was to promote the chemical industry and also to inform the people of its vast importance to national interests.

What is to be the outcome of the government's suit against the Chemical Foundation? The trial now under way at Wilmington, Del., is likely to cover a period of several weeks. The issue involved is of decided interest to the chemical industry in the United States. *Chem. & Met.* is following developments closely and during the period of the trial will present a weekly digest of its progress.

The charge was made by Kresel that there is an "invisible plaintiff" in the person of "the great German chemical trust." He drew a gloomy picture of a return of the German chemical monopoly in this country if the court upholds the government's demands.

Textile Alliance Cleared

One of the few positive developments in the early stages of the trial came in the clearing of the Textile Alliance of all charges of conspiracy in the seizure and sale of the patents. When Albert M. Paterson, president of the Textile Alliance, took the stand, he admitted his desire to have the Alliance combine with the Foundation. He stated that the purpose of both organizations is to prevent abuses in business. Moreover, he testified to the value of the Foundation's achievements, saying that today his industry finds it unnecessary to go outside of America for dyes. The reason for lack of a definite union between the two organizations developed to be the unwillingness of the executive committee of the Alliance to bring such a union about.

The trial will in all likelihood cover a period of several weeks. At present the opening guns have been fired, but the detailed arguments, the testimony of witnesses, the presentation of the case from other angles remain to be given.

National Lead Co. Negotiates for St. Louis Plant

E. J. Cornish, president of the National Lead Co., has confirmed reports that the Titanium Pigment Co., which is a subsidiary of the National Lead Co., is negotiating for the purchase of the plant of the Mineral Refining & Chemical Corporation, in St. Louis. The Titanium Pigment Co. manufactures "titanox," a new pigment composed of titanium oxide and blanc fixe. By securing a plant at St. Louis the company would be able to increase its output and also would be nearer the source of supply for barytes.

Dyeing Firms in Merger

Announcement was made last Wednesday that the United Piece Dye Works of Paterson, N. J., had obtained control of the Weidmann Silk Dyeing Co. It is stated that the companies will continue to operate as separate units, but will be conducted under the control of the United Piece Dye Works. This combination forms one of the largest silk-dyeing concerns in the country. In the announcement of the merger it was stated that the two have been merged under one management and control and the combined management will conduct these industries in their respective branches along the same lines as heretofore.

Match Industry in Poland

There are at present sixteen match factories in Poland, one having been established recently in former Russian Poland. Of this number, three are in former Austrian Poland, three in former German Poland, and the remaining ten in former Russian Poland. The matches are safety matches. About 50 per cent potassium chlorate is used in combination with antimony, sulphur and other substances. The principal wood is aspen, but pine and poplar are used occasionally. According to figures furnished by the Polish Ministry of Commerce, 84,706 cases, each case containing 5,000 boxes of 100 matches, were manufactured during the first 8 months of 1922. Exact figures for the last 4 months of the year are not available, but it is estimated that more than 50,000 cases were manufactured.

Supreme Court Holds Linseed Crushers Violated Sherman Act

Exchange of Prices and Other Information Through Armstrong Bureau Declared Unlawful—Reverses Decision of Lower Court and Orders Injunction

MANUFACTURERS in the same industry cannot exchange information as to sales and prices practically as a unit controlling the business of the industry without coming into conflict with the Sherman act, even though the information be cleared and distributed by an independent agency. So holds the United States Supreme Court in a decision June 4 reversing the action of the District Court for Northern Illinois in holding for the defendants in the government's suit against the American Linseed Oil Co. and eleven other crushers, and the Armstrong Bureau of Related Industries. The opinion, read by Associate Justice McReynolds, directed the District Court to grant the government the injunction it had sought.

The twelve linseed oil manufacturers were subscribers to the Armstrong Bureau. They controlled a large part of the business of their industry. They agreed to turn over to the bureau full reports of sales, quotations, offerings and other information. They were to receive through the bureau data on the market, trade and manufacturing conditions in the industry, economies in manufacture and sale, information regarding credit of buyers, uniform cost-accounting systems, fair freight rates, standardization of products and other information and help.

The District Court held that this agreement was not unlawful and denied the government's petition for an injunction against the practice as a violation of the Sherman act.

Lower Court Reversed

In concluding the Supreme Court decision reversing the lower court, Justice McReynolds, in his opinion, said:

"The obvious policy, indeed the declared purpose, of the arrangement was to submerge the competition theretofore existing among the subscribers and substitute 'intelligent competition,' or 'open competition'; to eliminate 'unintelligent selfishness' and establish '100 per cent confidence'--to the end that the members might 'stand out from the crowd as substantial co-workers under modern co-operative business methods.'

"In American Column & Lumber Co. vs. United States, we considered a combination of manufacturers got up to effectuate this new conception of confidence and competition and held it within the inhibition of the Sherman act because of inevitable tendency to destroy real competition, as long understood, and thereby restrain trade. Our conclusion there cannot be reconciled with the somewhat earlier opinion and judgment of the court below. They are in direct conflict.

"The Sherman act was intended to secure equality of opportunity and to protect the public against evils commonly incident to monopolies and those abnormal contracts and combinations which tend directly to suppress the conflict for advantage called competition--the play of the contending forces ordinarily engendered by an honest desire for gain.

"Certain it is that the defendants are associated in a new form of combination and are resorting to methods which are not normal. If, looking at the entire contract by which they are bound together, in the light of what has been done under it, the court can see that its necessary tendency is to suppress competition in trade between the states, the combination must be declared unlawful. That such is its tendency, we think, must be affirmed. To decide otherwise would be wholly inconsistent with the conclusion reached in American Column & Lumber Co. vs. United States, *supra*.

"The record discloses that defendants, large manufacturers and distributors powerful factors in the trade of commodities restricted by limited supplies of raw material (linseed), located at widely separated points and theretofore conducting independent enterprises along customary lines, suddenly became parties to an agreement which took away their freedom of action by requiring each to reveal to all the intimate details of its affairs. All subjected themselves to an autocratic bureau, which became organizer and general manager, paid it large fees and deposited funds to insure their obedience. Each subscriber agreed to furnish a schedule of prices and terms and adhere thereto—unless more onerous ones were obtained--until prepared to give immediate notice of departure therefrom for relay by the bureau. Each also agreed, under penalty of fine, to attend a monthly meeting and report upon matters of interest to be there discussed; to comply with all reasonable requirements of the bureau; and to divulge no secrets.

Not Bona Fide Competitors

"With intimate knowledge of the affairs of other producers and obligated as stated, but proclaiming themselves competitors, the subscribers went forth to deal with widely separated and unorganized customers necessarily ignorant of the true conditions. Obviously they were not bona fide competitors; their claim in that regard is at war with common experience and hardly compatible with fair dealing.

"We are not called upon to say just when or how far competitors may reveal to each other the details of their affairs. In the absence of a purpose to monopolize or the compulsion that results from contract or agreement, the individual certainly may exercise great freedom; but concerted action through combination presents a wholly different problem and is forbidden when the necessary tendency is to destroy the kind of competition to which the public has long looked for protection. The situation here questioned is wholly unlike an exchange where dealers assemble and buy and sell openly; and the ordinary practice of reporting statistics to collectors stops far short of the practice which defendants adopted. Their manifest purpose was to defeat the Sherman act without subjecting themselves to its penalties.

"The challenged plan is unlawful and an injunction should go against it as prayed in the original bill. The case will be remanded to the court below with instructions to issue such an injunction and promptly to take any further action necessary to carry this opinion into effect. Reversed."

Financial Notes

Parke Davis & Co. have declared a quarterly dividend of 50c. and an extra dividend of 75c. per share, both payable June 30. For the preceding quarter an extra dividend of $1.25 per share had been paid.

The United Zinc Smelting Corporation for the last calendar year shows total sales of $1,738,965 and operating profit, after costs and expenses, of $153,914. In 1921 the corporation reported an operating loss of $45,862.

The Owens Bottle Co. has declared a quarterly dividend of 75c. a share on the common stock and the regular quarterly dividend of $1.75 a share on the preferred, both payable July 2 to holders of record June 15.

The American Glue Co. has passed the regular quarterly dividend of $1 per share on common stock. Sales for the 4 months to April 30 were 28 per cent more than in corresponding period of 1922. Unsatisfactory trade conditions at present and undetermined questions of government taxes influenced action to pass the dividend.

The Goodyear Tire & Rubber Co. has declared a dividend of $2 on the prior preference voting trust certificates, payable July 1 to holders of record June 15.

At the annual meeting of the Pure Oil Co., President Dawes announced that he would recommend a reduction in the dividend rate on common stock from 8 per cent to 6 per cent.

The Lee Rubber & Tire Corporation will issue 65,000 shares of increased capital to acquire the assets of the Republic Rubber Co. The remainder of the stock will remain in the treasury.

United Kingdom Increases Imports of Chemicals in First Quarter of Year

Heavy Increase in Arrivals of Cream of Tartar—Decline in Glycerine Receipts—Small Imports of Coal-Tar Intermediates

IMPORTS of chemicals, other than drugs and dyestuffs, into the United Kingdom in the first quarter of 1923 increased in quantity, with the exception of glycerine, compared with the same periods in 1921 and 1922, according to a report received by the Department of Commerce from the office of the consulate-general in London. The increase over 1922 figures in some cases was nearly 200 per cent, and in the case of cream of tartar the increase was more than 9,400 per cent.

In the drugs sections, the returns for the first quarter indicated substantial increases in imports over 1922 figures, but did not reach the 1921 volume.

In dyes and dyestuffs, there were renewed imports of coal-tar intermediates and of synthetic indigo during the first 3 months of 1923, there having been no receipts of either in the corresponding period of 1922. But compared with 1921, intermediates totaled 58,000 lb., against 488,700 lb. in the same period of 1921, while imports of synthetic indigo increased to 804,400 lb., compared with 702,100 lb. 2 years ago. Imports of alizarin were 522,300 lb. in the first quarter of 1923, compared with 635,500 lb. in the corresponding period of 1922, while imports of "all other sorts" of finished coal-tar dyes, not enumerated, increased to 915,400 lb. in the 1923 period, compared with 875,000 lb. in the first quarter of 1922. Imports of natural indigo were 15,200 lb., compared with 40,200 lb. in the first quarter of 1922. Of extracts for dyeing, cutch increased to 1,284,600 lb. in the first 3 months of 1923, compared with 948,800 lb. in the corresponding period last year, while "all other sorts" declined slightly, being 2,234,200 lb., compared with 2,276,300 in the first quarter of 1922. Prices paid for alizarin averaged higher than in 1922, and prices for unenumerated coal-tar dyes averaged lower. Average prices for natural indigo were higher and prices for cutch and other extracts for dyeing averaged lower.

Comparative figures of quantity imports of chemicals and drugs during the first quarter of 1923 contrasted with the corresponding period of 1922 included: acetic acid, 1,645 tons—799 tons; tartaric acid, 6,223 cwt.—2,223 cwt.; bleaching materials, 8,696 cwt.—7,688 cwt.; borax, 17,606 cwt.—6,977 cwt.; calcium carbide, 175,028 cwt.—162,861 cwt.; glycerin, crude, 2,688 cwt.—9,376 cwt.; glycerin, distilled, 1,009 cwt.—2,288 cwt.; red lead and orange lead, 9,294 cwt.—4,444 cwt.; nickel oxide, 6,366 cwt. (no 1922 figures); potassium nitrate, 42,906 cwt.—26,775 cwt.; other potassium compounds, 1,246,487 cwt.—964,794 cwt.; sodium nitrate, 551,869 cwt.—238,814 cwt.; other sodium compounds, 85,374 cwt. — 35,439 cwt.; cream of tartar, 13,644 cwt.—143 cwt.; zinc oxide, 1,906 tons—1,161 tons; quinine and quinine salts, 324,219 oz.—139,368 oz.; bark, cinchona (bark Peruvian, etc.) 1,218 cwt.—618 cwt.

Export figures of chemicals and drugs for the first quarter of 1923 show increases in the majority of products as compared with the same period of 1922, but in the latter period there were a number of decreases as compared with 1921 which have not been fully recovered this year. The present trend, however, is toward higher exports in 1923.

Imports of Coal-Tar Dyes Increase in May

Imports of coal-tar dyes through the port of New York during May totaled 254,327 lb., with an invoice value of $292,340, according to the monthly report issued by the Chemical Division of the Department of Commerce and the Chemical Section of the Tariff Commission. This compares with 179,309 lb., valued at $185,344, in January; 191,709 lb., valued at $199,640, in February; 312,809 lb., valued at $301,436, in March, and 242,022 lb., valued at $256,751, in April.

The largest quantity importations of dyes in May were Ciba Scarlet, Ciba Bordeaux B, Alizarin Blue Black, Xylene Light Yellow 2 G, and Trisulphon Brown B. Of the total in May, 39 per cent was shipped from Switzerland, 39 per cent from Germany, 13 per cent from Italy, 5 per cent from England, 3 per cent from France and 1 per cent from Canada. In April, 42 per cent came from Switzerland, 37 per cent from Germany, 18 per cent from Italy, 2 per cent from Canada and 1 per cent from England.

The May report includes for the first time imports for consumption of synthetic aromatic chemicals, medicinals, photographic chemicals, intermediates and other coal-tar products which appear in the tariff act of 1922 in paragraphs 27 and 28. The aggregate of this imported during the month was 191,496 lb., with an invoice value of $90,524. Color lakes and bacteriological stains are not included.

German Soap Trade Depressed

The erratic and continued downward trend of the mark, the cost of basic oils which must be obtained abroad and the inability of the German people to absorb the output of the factories under prevailing prices has brought the soap industry of Germany to a rather discouraging pass, according to advices received by the Department of Commerce.

Trade Notes

R. B. French, of the New York office of Harshaw, Fuller & Goodwin Co., has left on a business trip to New England.

H. S. Chatfield, of the Kasebier-Chatfield Shellac Co., returned last week from a trip in Western territory.

The Oil Trades Association of New York will hold its annual outing at Massapequa Inn, Massapequa, L. I., on June 21. Albert J. Squier is chairman of the entertainment committee.

Sales of crystalline graphite in 1922 amounted to 1,849,776 lb. This was an increase of 56 per cent as compared with 1921. The amount of amorphous graphite sold was 2,200 short tons, or an increase of 19 per cent over 1921.

The Endicott-Johnson Co. has purchased land in St. Louis for the purpose of erecting a distributing warehouse in the Middle West and Southwest.

Following the recent acquisition of the California Chemical Co., San Diego, Calif., by Stanley H. Barrows, president of the National Kellastone Co., Porterville, Calif., plans are being perfected for the dissolution of the purchased company and the organization of the California Chemical Corp., to take over the plant, leaseholds and other properties. Mr. Barrows will head the new company. The plant is now being operated as the San Diego division of the Sierra Magnesite Co., of which Mr. Barrows also is president. Extensions and improvements will be made in the present works for increased output of flake magnesium chloride, potash and epsom salts.

Recent statistics show that rich deposits of clay are now to be found in seventeen counties in the state of Indiana. What is said to be the first pottery established in the state was located at Bloomingdale in 1840.

With the installation of automatic machinery, the Whitall-Tatum Co., Millville, N. J., manufacturer of bottles, vials, etc., is planning for the early discontinuance of its caster department. It is likely that the change will be made at the close of the present blast.

Directors and officers of the Standard Oil Co. of New Jersey have been re-elected.

Nearly 36 per cent of the record crude oil production of 1,937,767 bbl. per day in April was the result of operations in California. Daily output in California was 689,865 bbl.

The price of foreign dyes in Swatow, China, in 1922 declined gradually and the importation of aniline dyes showed an increase in value of 22,051 haikwan taels ($18,247), as compared with the figures for the same quarter of last year, according to a memorandum prepared by the commissioner of customs in Swatow, describing the trade of that port for the quarter ended Dec. 31, 1922.

Facts and Figures That Influence Trade in Chemical Products

Market Conditions

Current Prices Imports and Exports The Trend of Business

Quiet Trading Movement Gives Easy Tone to Prices Throughout Chemical List

Imported Offerings Are Still Under Selling Pressure and Large Consuming Industries Are Well Covered for Nearby Needs

THE weighted index for the past week indicates a higher average sales price for chemicals. This is due to advances in cottonseed oil, which is the basic oil in the vegetable oil group. As far as the price tendency of chemicals is concerned, the trend was more toward lower than higher levels.

Consuming trades continue to take large amounts of chemicals but new orders from this source have fallen off in volume and curtailed production as promised for the summer months has been anticipated in the markets for raw materials and there is a natural reaction from the active trading which characterized domestic markets in the first quarter of the year. Such a condition naturally has a direct bearing on prices and well informed members of the trade say values for chemicals may hold an easy position until indications of fall requirements are more clearly understood. There is a tendency on the part of manufacturers to carry only limited stocks of raw materials and trust to future developments as a guide for placing orders later on.

Stocks of different foreign chemicals are held in the local market and it is difficult to hold prices steady when buyers are apathetic. Most importers have figured in arsenic transactions and stocks have been held awaiting a heavy call for calcium arsenate. No improvement has yet taken place and arsenic prices are hard to maintain. Among other imported materials which are selling in buyers' favor are carbonate of potash, caustic potash, oxalic acid, permanganate of potash, cyanide of soda, prussiate of soda, sulphide of soda, and copper sulphate.

The easy position of some metals is reflected in lower prices for metal salts. This is noticeable in the case of tin products, some of which were lowered at the beginning of the month. Copper oxide and copper carbonate have been unusually active this season and they are in a strong position as a result of limited offerings. Copper sulphate, however, has not sold up to expectations and the influx of low priced foreign goods has depressed the market.

Acids

Citric Acid.—A better tone was noted in the market and inquiry for moderate sized lots was more regular. Some reports credited small-lot sales of imported at 53@53½c. per lb. The lowest price named for imported was 52c. per lb. and this figure was said to be below replacement costs. Domestic grades are pretty well sold up with first hands holding quotations at 49@50c. per lb.

Formic Acid.—Demand is of fair proportions but stocks on hand have been ample and there has been no change in market conditions. Imported grades are commanding the most attention because of price considerations. The quotation for 85 per cent acid is held at 14@15c. per lb. Domestic offerings are generally held at an inside figure of 16c. per lb.

Arsenic Still Declining — Imported Copper Sulphate Sells at New Low—Prussiate of Potash Neglected — Permanganate of Potash Weak—Caustic Potash Quiet and Easy—Fusel Oil Sold Up—Methyl-Acetone Advances.

Muriatic Acid. — The movement against old orders is still in evidence and producers are not carrying any surplus stocks, so that offerings for new account are restricted. Consumers, however, seem pretty well covered. Prices are steady at 90c.@$1 per 100 lb. for 18 deg. and $1.75@$2 for 22 deg. in tanks.

Nitric Acid.—Prices are holding on an unchanged basis but there was little else in the current market to distinguish trading. Demand is seasonable and regular deliveries are passing to the several consuming industries but new business is running light. Sellers quote 36 deg. at $4.50@$5 per 100 lb. and 42 deg. at $5.25@$5.75 per 100 lb.

Oxalic Acid.—There has been very little if any improvement in demand and this is reflected in the easy tone to prices. Offerings of imported were available throughout the week at 13@13½c. per lb. Stocks are fairly large and with consumers taking hold only in a hand to mouth fashion, there is not much in sight on which to base hopes of a consistently higher market.

Sulphuric Acid.—Consuming interest is less keen but consumption is reported to be above normal standards. Resale lots have not figured to any extent in recent transactions and with producers in control of the market and not carrying surplus stocks, prices are well established with sellers' views at $9.50@$12 per ton for 60 deg. and $15@$16 per ton for 66 deg.

Tartaric Acid.—Offerings of foreign makes have been free and with prices easy a fair volume of business was put through during the week. Some reports credit sales of imported at 36c. per lb. but 36½c. per lb. was asked in many directions. Makers of domestic tartaric are finding a good call for contract deliveries and are holding quotations at 37½c. per lb.

Potash

Bichromate of Potash.—First hands are quoting 11½c. per lb. as an inside price and in some cases there is no desire to accept much business at that figure. However, it is possible to locate material at 11¼c. per lb. Some producers are poorly supplied and prices depend upon seller. Trading is not featured in any way either for home or export account.

Caustic Potash.—Interest centers in imported grades with no new developments during the week. Different importers hold stocks in the local market. In some cases they are not trying to force sales while others are eager to turn over holdings. The lowest price heard was 7½c. per lb. and there is a range upward according to seller. For domestic caustic 9c. per lb., f.o.b. works, is quoted.

Carbonate of Potash.—Importers are not finding a ready outlet and a slow week was generally reported. On 90-95 per cent there were offerings at 6¾c. per lb. Moderate buying in the 80-85 per cent variety was reported on a basis of 6½c. per lb. Hydrated 80-85 per cent is easy with quotations at 7½c. per lb. and very little demand from consumers.

Chlorate of Potash.—Some round lots of imported have recently passed to consumers with different reports about the prices at which this material was sold. It is stated that the buyers in question generally are giving the lowest prices obtainable. In the spot market holders of stocks are quoting 7½c. per lb. as the inside price. Domestic makes are also steady with 8½c. per lb. works the asking price.

Permanganate of Potash.—This material has been irregular in price. A

short time ago cables from primary points abroad quoted shipments of permanganate at higher prices. In anticipation of an advance in the spot market, different holders of stocks put up their prices to 19c. per lb. and many have continued to quote at that level. A few holders, however, have accepted bids at relatively low prices and sales are said to have been made at 17½c. per lb. At present spot goods may be quoted at 17½c. to 19c. per lb., according to seller. It is stated that this material is included in the list on which government surveys are being made and some members of the trade believe that tariff changes are not improbable.

Prussiate of Potash.—The market for red prussiate was practically neglected and prices are nominally repeated at 65@68c. per lb., according to seller. Yellow prussiate also is finding a restricted outlet and competition from other materials undoubtedly has cut down demand for this chemical in recent months. Prices for yellow prussiate are 35@36c. per lb. for spot material with shipments as low as 34c. per lb.

Sodas

Bichromate of Soda.—Prices for bichromate of soda are largely a matter of seller. Some prominent factors are quoting 9c. per lb. as their inside price. Others offer at 8½c. per lb. and independent sellers say that sales have been made at the inside figure, and it is believed that fairly large lots can be obtained at that level. Competition, however, is not very keen and it seems probable that stocks in some sellers' hands are not very large.

Caustic Soda.—A very dull period is reported for this commodity. The export situation has not changed for the better and foreign markets are not interested at present price levels. The f.a.s. quotation for standard brands is reported to be easy at 3.35c. per lb. On outside brands 3.22½c. per lb. is still quoted but firm bids might find sellers at lower figures. Domestic consumers are taking regular deliveries and that side of the business is regarded as satisfactory. Prices for domestic delivery are holding at 2½c. per lb. works, for car lots, basis 60 per cent. Dealers also hold spot goods on a steady level of 3½c. per lb. and upward on a quantity basis.

Cyanide of Soda.—A fairly wide range in prices, according to seller, is noted. Imported material has sold as low as 20c. per lb. and in some quarters it was stated that this price still could be done. In other directions 21½@22c. per lb. was given as the market price for imported. Domestic cyanide is generally held at 22@23c. per lb.

Nitrate of Soda.—Demand for spot material has been quiet in all consuming markets and holders of stocks have been willing to shade prices in order to interest buyers. There is no definite spot price for the time being as buyers have heard prices ranging from $2.40 to $2.50 per 100 lb. Shipment prices are holding at the schedule recently announced. Reports from primary points say that exports of nitrate from Chile for first half of May were only 25,000 metric tons, partly explained by the fact that sales in April were small pending announcement of new prices.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	**178.17**
Last week	177.64
June, 1918	272.00
June, 1919	229.00
June, 1920	274.00
June, 1921	147.00
June, 1922	157.00

Cottonseed oil occupies an important position in the weighted index and the advance in this commodity more than offset declines in copper sulphate, barium, chloride and formaldehyde.

Nitrite of Soda.—Buyers have remained out of the market and prices are very weak with considerable competition between domestic and imported offerings. There were imported stocks on the market last week at 7¾c. per lb. Domestic makes were generally held at 8c. per lb. but it was stated that some sellers of domestic would meet foreign competition.

Prussiate of Soda.—There was not much trading to test prices but sellers say that values already are very low and many hold that further declines are improbable. Imported material is openly quoted at 15½c. per lb. but this might be shaded on actual transactions. Domestic prussiate is offered at 16c. per lb. by prominent producers.

Sulphide of Soda.—Greater competition from imported sulphide gave an easier feeling to the market for domestic. This was further intensified by a very slow trading period. Prices for domestic, however, show no change and fused is quoted at 4½c. per lb. and broken at 5½c. per lb. Crystals especially are reported as steady with 2¾c. per lb. as the lowest price heard. Imported fused was offered at 3½c. per lb. for spot and shipment.

Miscellaneous Chemicals

Arsenic—The fact that buying orders were light held the market in an easier position. For some time certain holders have been willing to shade the quoted prices. On that account it is difficult to report the market weaker, but some factors who were quoting 14c. per lb. in the previous week were offering at 13¾c. per lb. and it is probable that 13½c. per lb. could have been done. There was some interest in futures, but this did not result in any business as far as could be learned. June-July shipments were offered by producers at 12½c. per lb. and the latter held shipments over the last half of the year at 11c. per lb.

Calcium Arsenate—There was no change of importance in the local market. Demand is very quiet and stocks have not been reduced to any extent. A little better call was reported for deliveries against old orders, but new business failed to make any gain. Prices are largely nominal, but are admitted to be easy at 16@16½c. per lb.

Copper Oxide—Grinders have been taking large amounts and producers have been pretty well sold up for some time. Imported material has been selling freely. Prices are quoted at 20@21c. per lb., depending on quantity and seller.

Copper Sulphate—Some good sized quantities of domestic sulphate have been taken out of the market, but new business is not large enough to stiffen prices and the market is easy in tone. Quotations for domestic large crystals are 5.75c. per lb. Imported sulphate has been a drug on the market and some round lots sold during the week at private terms, but below the quoted levels. The quoted prices were subject to sharp reductions and offerings were free at 4¾c. per lb., although some holders ask up to 5½c. per lb.

Formaldehyde—A few scattered lots are held by second hands and these goods can be bought at 14½c. per lb. With that exception the market is holding a steady course with first hands asking 14½@15c. per lb.

Fusel Oil—Prices for fusel oil are almost wholly nominal. A few lots of crude have reached the market and sales are reported at prices ranging from $3.30 to $3.60 per gal. Refined is difficult to locate and no prices are heard in any direction for prompt delivery. Production in Europe has been light for some months and imports have been very small. Competing materials which had cut down demand for fusel oil are in small supply and some uncertainty is felt about future supplies.

Tin Products—Tin crystals are now offered at 34½c. per lb. for June delivery and tin bichloride at 12½c. per lb. Tin oxide was unchanged at 48c. per lb. Lower prices for the metal are responsible for the easier position of the salts.

Methyl-Acetone—First-hands announced a 10c. advance in prices, reflecting higher producing costs. The revised trading basis, in 100-gal. drums, is 92@95c. per gal., the inside figure obtaining on carload lots. For tank car deliveries 90c. is asked.

Alcohol

No price changes occurred in the market for alcohol. The call for denatured was up to expectations and a steady undertone was reported from nearly all quarters. The special, No. 1 formula, was traded in on the basis of 35c. per gal. in drums. On the completely denatured, formula No. 1, the quotations ranged from 43@49c. per gal., as to style of container, etc. Ethyl alcohol. U. S. P., 190 proof, was offered at $4.70 per gal. Producers' agents offered methanol, 95 per cent, at $1.1[illegible] per gal., and the 97 per cent at $1.2[illegible] per gal.

Coal Tar Products

First Hands Report Steady Market on Phenol—Better Call for Naphthalene—Benzene Offered Freely

Actual offerings of phenol for immediate delivery were limited to odd lots here and there and no real selling pressure was in evidence. While traders admit that several lots of U.S.P goods sold down to 45c. per lb., quotations for resale parcels at the close stood nearer 50c. In any event spot prices on outside material were wholly nominal. Leading producers talked firmer prices on contract deliveries, and it was doubtful whether 30c. per lb. could have been shaded on nearby stuff. The "new production" is not yet a market factor. The past week witnessed improvement in the demand for naphthalene, both flake and ball, but prices underwent little if any change. Solvent naphtha was firmly maintained on moderate stocks, production being well sold up in most directions. Benzene was offered freely at the recently reduced level of prices. Cresylic acid on spot was unsettled. Salicylic acid was inactive and barely steady in certain quarters of the trade. Benzoic acid was firmer. Xylene, pure, met with a fair call and with little offering on spot the situation favors sellers.

Benzidine Base—Some irregularity was reported in prices and the market settled at 80@85c. per lb. The sulphate was neglected and prices of 70@75c. per lb. were considered nominal.

Benzoic Acid—Inquiry showed improvement and some traders entertained firmer views. It was reported that sales on spot went through at 77c. Quotations at the close, covering the U.S.P grade, ranged from 75@80c. per lb.

Beta-Naphthol—There were offerings on the ordinary grade at 22c. per lb., with intimation that this figure could be shaded on a firm bid. Several producers, however, continued asking 22½@23c. per lb.

Cresylic Acid—Importations have let up of late, but with the demand slow prices failed to improve. There were sellers on spot at $1.10@$1.15 per gal., the outside figure obtaining on the 97 per cent grade. Leading domestic producers have nothing to offer.

Alpha-Naphthylamine—Producers reported a steady market and prices of 35@37c. were maintained, the inside figure holding on round lots, ex-works.

Aniline Oil—Scattered business was put through at 16½c. per lb., less than carload lots. The inside price on carload business held at 16c. per lb. The undertone was steady.

Benzene—Most of the benzene moving into motor-fuel channels is traded in on a contract basis which assures a steady outlet for production. The recent drop in prices was the outcome of lower prices for gasoline. The market for the pure was quiet, leading interests asking 27@32c. per gal., the price depending upon the quantity, style of package, etc. On the 90 per cent grade 25c. was the nominal price for tank car shipments, f.o.b. works.

Naphthalene—Demand for spot goods was better and prices seemed to steady a little. Sales of flake again went through at 8¼c. It develops that some transactions in prompt shipment from works were placed at 8c. per lb. On ball naphthalene prices were wholly nominal at 9@9½c. per lb. Crude was unsettled abroad and based on cables received here late in the week fair quality merchandise could have been secured at 3@3¼c. per lb., c.i.f. basis. Intermediate makers showed only passing interest in crude.

Ortho-Toluidine — First-hands continue to quote from 14@15c. per lb., round-lot basis. A fair inquiry was reported from abroad.

Paranitraniline—The spot market was unsettled and closing prices ranged from 70@75c. per lb. It was reported that scattered business went through at a shade under 70c.

Phenol—The market was largely nominal so far as second-hand offerings were concerned, but late in the week most holders were asking around 50c. for spot material. Leading interests took a firmer view of the nearby situation based on reports that new production could not be reckoned with for some months to come. On contract business 30c. was the nominal closing price.

Salicylic Acid—Business was slow and while the undertone was barely steady prices showed no change.

Solvent Naphtha—The market was in a strong position in view of the soldup condition of leading producers. Demand was good. Quotations for contract deliveries ranged from 27@32c. per gal., f.o.b. works.

Xylol—There were offerings of spot material in the pure grade at $1 per gal. On contract 75c. represented the market. The demand was fair.

Chemical Salesmen to Hold Outing June 23

A. J. Binder, chairman of the entertainment committee of the Salesmen's Association of the American Chemical Industry, announces that the annual chicken-lobster dinner and games will be held at Pleasure Bay, N. J., on Saturday, June 23. An invitation is extended to members of the trade not affiliated with the association and a large attendance is expected. The "party" will leave New York at 10:30 a.m., by boat, from West 42nd St., but members located in the downtown section may connect with the steamer at the foot of Cedar St.

Lower Cable Rates

Lower cable rates to Central American points have been made by the All-America Cables. The announcement of the cable company quotes rates at 35c. a word to San Jose, Guatemala; La Libertad, Salvador; San Juan del Sur, Nicaragua; San Jose and Port Limon, Costa Rica; and to 40c. a word to all other places in Guatemala, Salvador, Nicaragua and all Spanish Honduras; and to 42c. a word to all other places in Costa Rica. Deferred service is at one-half rate.

Rubber Consumption in Germany Falls Off Sharply

The rubber trade in Germany has suffered materially as a result of the Ruhr situation, decline in marks and loss of export business in rubber goods. Consumption of rubber in Germany was 3,000,000 lb. in January and only 1,000,000 lb. in April. Exports have been aided somewhat by the withdrawal of high export taxes and the changing of regulations which made it difficult to obtain permits. Holland is the largest buyer of German rubber goods.

Vegetable Oils and Fats

Imported Linseed on Spot Lower—Crude Cottonseed Up—Good Call for China Wood—Tallow Declines

A BETTER feeling prevailed in the market for vegetable oils toward the close, but, with the exception of china wood oil, few round-lot transactions could be located. Shorts ran to cover in old crop cottonseed oil options, the advance in lard and grains causing some uneasiness in speculative quarters. Coconut oil steadied just a trifle on moderate offerings of copra. Buying interest in crude soya bean oil for shipment was lacking. The palm oils were dull and rather easy, reflecting the drop in tallow.

Linseed Oil—The market was steadier at the close on a moderate recovery in seed. Early last week domestic oil was traded in at $1.04 per gal. in cooperage, carload lots, July shipment, but later it was doubtful whether $1.05 could have been shaded. Spot oil of domestic make settled at $1.12@$1.14 per gal. August forward was nominal at $1.02 per gal. At one time a price of $1.00 was named on August-September-October business. Inquiry in the forward positions improved slightly, but the market, taken as a whole, was a rather dull affair. Imported linseed oil was unsettled and business went through ex-dock at lower prices. It was reported that distressed oil actually sold down to 95c. per gal., duty paid. Foreign linseed oil markets were inactive and slightly lower. Private estimates on the new domestic crop have not yet taken definite form, but most "experts" expect a fair increase in the acreage. Developments in Canada were not so favorable. Argentine offerings continue large. The Indian crop is moving freely and the exports for the past week reached the total of 784,000 bushels, nearly all of which was shipped to the United Kingdom. Shipments of flaxseed from the Argentine to the United States since the first of the year amounted to approximately 15,500,000 bu., while receipts of domestic seed at Minneapolis and Duluth, from September 1, 1922, to date, amounted to 8,900,000 bu. The stocks of seed at Minneapolis last week were placed at 28,852 bu., which compares with 19,136 bu. the week previous. Export demand for linseed cake was quiet, but crushers continued to quote around $34 per ton, f.a.s. New York.

Cottonseed Oil—The second half of the week brought with it a little more activity in cottonseed oil options and prices steadied. The advance in lard, together with higher markets for cotton and grains, caused shorts in July and September oil to run to cover. The fact that September oil has been at a discount for no apparent reason brought out support from traders who believe that a strong statistical situation in July could only mean an even stronger situation for September. The new cotton crop has not been doing well and, according to the Department of Agriculture, the condition as of May 25 was 71 per cent of normal. The average for the past 10 years was 73.6 per cent. Taking the condition as a basis operators do not look for much more than 11,000,000 bales from the 1923 crop. In view of the fact that we raised two short crops in succession a moderate increase for this season would hardly create a bearish situation. Cash demand for cottonseed oil and compound was fair. May consumption figures will not be available for another week or so, but private estimates on the disappearance range from 125,000 to 150,000 bbl. Crude oil sold in the southeast at 10c. per lb, tank cars, f.o.b. mills, an advance of ½c. for the week. Bleachable oil settled at 10½c. per lb. buyers' tanks, f.o.b. Texas common points. Lard compound closed at 13@13¼c. per lb., carload lots, f.o.b. New York.

China Wood Oil—Considerable interest was reported in August forward deliveries. At one time a price of 17½c. per lb. was named for August oil, but a flood of inquiries caused importers to withdraw offerings and the market steadied. Later business was placed in August forward at 19½c. per lb., and by the close of the week asking prices covering this position ranged from 21½@22c. per lb.

Coconut Oil—The coast market was dull, but no selling pressure was apparent and the quotations held at 8@8¼c. per lb., sellers' tanks, nearby and forward positions. In New York Ceylon type oil settled at 8⅜@8½c. per lb., sellers' tanks, prompt and nearby delivery. The steadiness in copra tends to support values. Copra held at 4⅞@5c. per lb., c.i.f. New York.

Soya Bean Oil—There were offerings of crude soya bean oil for forward shipment from the Pacific coast at 9⅞c. per lb., sellers' tanks, duty paid. Buying interest was lacking.

Fish Oils—It was reported that 4,000,000 menhaden were landed in the first week of the new season, which compares with 13,000,000 fish a year ago. Offerings of oil were limited and producers continued to quote 50c. per gal., tank car basis, f.o.b. works. No new business came to light. Newfoundland tanked cod oil was unchanged at 70c. per gal., in bbl., f.o.b. New York. Demand was slow.

Tallow and Greases—The sale of 300 drums of extra tallow at 7¼c. per lb., ex-plant, was reported last week, which compares with previous business at 7⅝c. per lb. The market was easy at the close. Oleo stearine was unchanged at 9c. per lb., carload basis. Yellow grease was lowered ¼c. to the basis of 6⅜c. per lb. on fairly low acid material.

Miscellaneous Materials

Glycerine. — Refiners continued to quote 17c. on the C. P. grade, in drums, spot and nearby delivery. Demand was fair and with no important change in crude sentiment in the market appeared firmer. C. P. was offered in the middle-west at 16½c., in drums, carload basis. In dynamite the trading was extremely slow and prices named were considered nominal, ranging from 15¾@16c. per lb., in drums, carload basis. Buyers' ideas were ½c. under the market. Crude glycerine was unsettled. The soap-lye, basis 80 per cent, held at 10½@11c. per lb., loose. On saponification, 88 per cent, nominal prices ranged from 12@12¼c. per lb., loose, carload lots.

Naval Stores.—The market went off on quiet business and at the close nominal quotations ranged from $1.03@$1.05 per gal., which compares with $1.06@$1.09 per gal a week ago. Southern markets were unsettled on limited domestic buying and virtually no export inquiry. The belief is growing that paint manufacturers are using substitutes to a greater extent than ever before. In rosins prices held about steady, although business in this field also was inactive. The lower grades held at $5.90@$6.20 per bbl. Pitch closed unchanged.

Shellac.—Prices steadied in some quarters on reports of slightly higher cables from Calcutta, but traders seemed to have little confidence in the "bull" side. Arrivals last week were small and with no additional pressure on ex-dock goods the spot quotations held at 58@60c. on T. N., 63c. on superfine orange and 70@71c. on bleached bonedry. Demand was routine only.

Lithophone.—A little imported material was around at concessions, but domestic producers continued to quote the market firm at 7@7¼c. per lb., carload lots, nearby positions.

White Lead, Etc.—The market for pig lead was a shade easier, but with no change in the "official" price the pigments were left unchanged. The metal was offered at 7¼c. per lb., New York. Deliveries of white lead against existing contracts are large enough to keep stocks down and corroders regard the market as fairly steady, notwithstanding the recent reduction in prices for pig lead. Standard dry white lead, basic carbonate, held at 9¾c. per lb. in casks, carload lots. Red lead, dry, was, offered by producers at 11¾c. per lb. Litharge closed at 10¾@11c. per lb.

Zinc Oxide—Domestic production is well sold up and with no important price changes in the metal the market held at 8@8¼c. per lb. on the American process, lead free. French process, red seal, closed at 9¾c. per lb.

London Tallow Auction

At the weekly auction in London, held June 6, 1,795 casks of tallow were offered for sale, but only 960 casks were sold. Prices went off 6 pence per cwt.

Imports at the Port of New York

PHOSPHATE—914 bg. bone, Rotterdam, H J Baker & Bro.

POTASSIUM SALTS—60 dr. permanganate, Hamburg, National City Bank ; 181 dr permanganate, Hamburg, A. Klipstein & Co., 100 bbl chlorate, Hamburg, Innis, Speiden & Co , 200 cks and 200 dr. chlorate, Marseilles, Asia Banking Corp ; 300 csk chlorate, Marseilles, Order ; 200 csk. perchlorate, Marseilles, Order ; 6,000 bg muriate and 500 bg. sulphate, Bremen, Potash Importing Corp of Am.; 75 dr caustic, Hamburg, Peters, White & Co., 250 bg. chlorate, Marseilles, Meteor Products Co., 250 bg chlorate, Marseilles, Order

PYRIDINE—6 dr , Rotterdam, Lunham & Moore.

QUEBRACHO—7,840 bg., Buenos Aires, Fourth Atlantic Nat'l Bank of Boston ; 1,710 bg , Buenos Aires, First Nat'l Bank , 2,067 bg , Buenos Aires, Guaranty Trust Co., 285 bg., Buenos Aires, Order

QUICKSILVER—1,000 fl., Seville, Order ; 1,000 fl., Alicante, National City Bank ; 50 fl , Vera Cruz, Poillon & Poirier , 5,000 fl , London, Order

QUININE—2 cs , Rotterdam, R. W. Greeff & Co , 20 cs , Rotterdam, Mallinckrodt Chem Works , 4 cs., Rotterdam, Order.

SHELLAC—43 cs , Rotterdam, A. Hurst & Co , 30 bg garnet, Hamburg, Kasebier-Chatfield Shellac Co.

SIENNA—50 csk., Leghorn, J. L Smith & Co

STARCH—150 bg potato, Stein, Hall & Co., 1,000 bg potato, Catz American Co.

SODIUM SALTS—10,930 bg. nitrate, Iquique, Du Pont de Nemours & Co ; 120 bbl hyposulphate, Marseilles, Order , 168 cs cyanide, Marseilles, Nat'l City Bank , 187 cs. cyanide, Havre, Asia Banking Corp , 13,916 bg nitrate, W. R Grace & Co , 2,191 bg nitrate, Valparaiso, W R Grace & Co ; 100 dr sulphite, Bristol, R F. Downing & Co ; 125 bg. fluoride, Marseilles, Nat'l City Bank , 112 cs cyanide, Marseilles, Asia Banking Corp.; 100 bbl. hyposulphite, Marseilles, E M Sergeant & Co., 120 bg do , Marseilles, Order

STRONTIUM NITRATE—39 csk , Hamburg, A Klipstein & Co

SUMAC—700 bg , Barcelona, Order , 10 bg , Marseilles, Order , 1,250 bg., Palermo, Order

TALC—200 bg , Genoa, Order , 600 bg Bordeaux, L. A. Salomon & Bros.; 700 bg , Genoa, L A Salomon & Bros , 750 bg , Genoa, Ital. Disc & Trust Co., 300 bg., Genoa, C. B Chrystal & Co., 200 bg. Genoa, Hammill & Gillespie

TARTAR—42 csk , Naples, Tartar Chemical Works; 150 sk , Marseilles, Tartar Chemical Works , 128 sk , Marseilles, C. Pfizer & Co.; 426 bg., Marseilles, Royal Baking Powder Co , 280 bg , Marseilles, C. Pfizer & Co.; 60 csk , Marseilles, Tartar Chemical Works , 765 sk., Oran, Tartar Chemical Works , 339 sk , Oran, C Pfizer & Co ; 11 sk., Valparaiso, C Pfizer & Co., 320 bg., Marseilles, Royal Baking Powder Co ; 80 bbl Marseilles, Tartar Chemical Works; 122 csk crude, Palermo, Royal Baking Powder Co

TARTRATE OF LIME—110 bg , Marseilles, Order ; 110 bg., Marseilles, C. Pfizer & Co.

VERMILION—16 csk., London, Pomeroy & Fischer

WAXES—22 bg bees, Aden, Order ; 900 bg. montan, Bremen, Order ; 67 bg carnauba, Para, International Acceptance Bank ; 110 cs. bees, Havre, Strohmeyer & Arpe ; 11 bg bees, Coquimbo, W. R. Grace & Co.; 32 bg., do., Talcahnano, Duncan Fox & Co.; 47 sk., Valparaiso, W R. Grace & Co.; 50 cs bees, Hamburg, Innis, Speiden & Co.

WHITING—101 bbl., Hamburg, Order

WHITE PIGMENT—224 bbl Christiania, Titanium Pigment Co.

ZINC CHLORIDE—169 csk , Hamburg, Pfaltz & Bauer.

ZINC OXIDE—330 bbl., Marseilles, Order.

ZINC WHITE—33 csk., Bristol, Reichard-Coulston, Inc.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb.	$0 38 –	
Acetone, drums	lb	.25 –	25½
Acid, acetic, 28%, bbl.	100 lb	3 38 –	3 50
Acetic, 56%, bbl.	100 lb.	6 75 –	7 00
Glacial, 99½%, bbl.	100 lb	12 00 –	12 50
Boric, bbl.	lb	10½–	
Citric, kegs	lb	49 –	52
Formic, 85%	lb	.14 –	16
Gallic, tech.	lb.	45 –	50
Hydrofluoric, 52%, carboys	lb	.12 –	12½
Lactic, 44%, tech., light, bbl.	lb.	.11½–	12
22% tech., light, bbl.	lb	.05½–	06
Muriatic, 18° tanks	100 lb.	90 –	1 00
Muriatic, 20°, tanks,	100 lb.	1.00 –	1 10
Nitric, 36°, carboys	lb	04½–	.05
Nitric, 42°, carboys	lb.	06 –	.06½
Oleum, 20%, tanks	ton	18 50 –	19 00
Oxalic, crystals, bbl.	lb.	.13 –	13½
Phosphoric, 50% carboys	lb.	07½–	08½
Pyrogallic, resublimed	lb	1 50 –	1 60
Sulphuric, 60°, tanks	ton	9 50 –	11 00
Sulphuric, 60°, drums	ton	13 00 –	14 00
Sulphuric, 66°, tanks	ton	16 00 –	16 50
Sulphuric, 66° drums	ton	20 00 –	21 00
Tannic, U.S.P., bbl.	lb.	.65 –	.70
Tannic, tech., bbl	lb.	.45 –	.50
Tartaric, imp., powd., bbl.	lb	.36½–	
Tartaric, domestic, bbl.	lb.	.37½–	
Tungstic, per lb.	lb.	1.10 –	1 20
Alcohol, butyl, drums, f.o.b. works.	lb	.26 –	.28
Alcohol ethyl (Cologne spirit), bbl	gal	4 75 –	4 95
Ethyl, 190 p'f U.S.P., bbl	gal	4 70 –	
Alcohol, methyl (see Methanol)			
Alcohol, denatured, 190 proof			
No. 1, special bbl	gal	41 –	
No. 1, 190 proof, special, dr	gal.	35	
No. 1, 188 proof, bbl	gal	42 –	
No. 1, 188 proof, dr	gal	36 –	
No. 5, 188 proof, bbl	gal	40 –	
No. 5, 188 proof, dr	gal	.34 –	
Alum, ammonia, lump, bbl	lb.	03½–	03¾
Potash, lump, bbl	lb	02¾–	03½
Chrome, lump, potash, bbl.	lb.	.05¼–	06
Aluminum sulphate, com., bags	100 lb.	1 50 –	1 65
Iron free bags	lb	.02½–	.02¾
Aqua ammonia, 26°, drums.	lb	.06¼–	.07¼
Ammonia, anhydrous, cyl	lb.	.30 –	30½
Ammonium carbonate, powd casks, imported	lb.	.09½–	.10
Ammonium carbonate, powd domestic, bbl	lb	.13 –	.14
Ammonium nitrate, tech., casks	lb	.10 –	11
Amyl acetate tech., drums	gal	3 50 –	3 75
Arsenic, white, powd., bbl	lb	13½–	14¼
Arsenic, red, powd., kegs	lb	14½	
Barium carbonate, bbl.	ton	70 00 –	75 00
Barium chloride, bbl	ton	83 00 –	85 00
Barium dioxide, drums	lb	.18 –	18½
Barium nitrate, casks		.08 –	08½
Barium sulphate, bbl.	lb	04 –	.04½
Blanc fixe, dry, bbl.	lb	.04 –	.04½
Bleaching powder, f.o.b. wks., drums	100 lb	1 90 –	
Spot N. Y. drums	100 lb	2 40 –	
Borax, bbl	lb	.05¼–	05½
Bromine, cases	lb.	28 –	30
Calcium acetate, bags	100 lb	4 00 –	4 05
Calcium arsenate, dr.	lb	16 –	16½
Calcium carbide, drums	lb	05¼–	05½
Calcium chloride, fused, drums	ton	22 00 –	23 00
Gran. drums.	ton	28 00 –	30 00
Calcium phosphate, mono, bbl.	lb	.06½–	.07
Camphor, cases	lb	.86 –	.88
Carbon bisulphide, drums	lb.	07 –	07½
Carbon tetrachloride, drums	lb.	09½–	10
Chalk, precip.—domestic, light, bbl	lb.	.04½–	.04½
Domestic, heavy, bbl.	lb.	.03½–	.03½
Imported, light, bbl	lb.	.04½–	.05
Chlorine, liquid, tanks, wks	lb	.05½–	.05½
Cylinders, 100 lb., wks	lb.	06 –	06½
Cylinders, 100 lb., spot	lb.	.09 –	
Chloroform, tech., drums	lb.	.35 –	38
Cobalt oxide, bbl.	lb.	2 10 –	2 25
Copperas, bulk, f.o.b. wks.	ton	20 00 –	21 00
Copper carbonate, bbl.	lb.	19 –	.20
Copper cyanide, drums	lb	47 –	50
Coppersulphate, dom., bbl.	100 lb.	5 75 –	
Imp. bbl.	100 lb.	4 75	5 00
Cream of tartar, bbl.	lb.	.25½–	26½
Epsom salt, dom., tech., bbl.	100 lb.	1.90 –	2.15
Epsom salt, imp., tech., bags	100 lb.	.90 –	1 00
Epsom salt, U.S.P., dom., bbl.	100 lb.	2.50 –	2.60
Ether, U.S.P., drums	lb.	.13 –	.15
Ethyl acetate, 85%, drums	gal.	.80 –	.81
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 –	1.00
Formaldehyde, 40%, bbl	lb	$0 14½–	$0 15
Fullers earth—imp., powd., net	ton	30 00 –	32 00
Fusel oil, ref., drums	gal	–	
Fusel oil, crude, drums	gal.	3 30 –	3 60
Glaubers salt, wks., bags	100 lb	1 20	1 40
Glaubers salt, imp., bags	100 lb	90 –	95
Glycerine, c.p., drums extra	lb	17 –	.17½
Glycerine, dynamite, drums	lb	15¾	16¼
Glycerine, crude 80%, loose	lb	10½–	11
Iodine, resublimed	lb	4 55 –	4 65
Iron oxide, red, casks	lb.	12 –	18
Lead:			
White, basic carbonate, dry, casks	lb	.09¾–	10
White, basic sulphate, casks	lb	09½–	
White, in oil, kegs.	lb.	12½–	.14
Red, dry, casks	lb	11½–	.12
Red, in oil, kegs	lb	13½–	.15
Lead acetate, white crys., bbl.	lb	14 –	14½
Brown, broken, casks	lb	13	13½
Lead arsenate, powd., bbl	lb	23 –	24
Lime-Hydrated, bbl	per ton	16 80 –	17 00
Lime, Lump, bbl	280 lb	3 63 –	3 65
Litharge, comm., casks	lb	10¾	11
Lithophone, bags	lb	07 –	07½
in bbl	lb	07	07¾
Magnesium carb., tech., bags	lb	08 –	08½
Methanol, 95%, bbl	gal	1 18 –	1 20
Methanol, 97%, bbl	gal	1 20 –	1 22
Nickel salt, double, bbl.	lb	10½–	
Nickel salts, single, bbl.	lb	11½	
Phosgene		60 –	75
Phosphorus, red, cases	lb	–	
Phosphorus, yellow, cases	lb	35 –	40
Potassium bichromate, casks	lb	11½–	12
Potassium bromide, gran., bbl	lb	19 –	.20
Potassium carbonate, 80-85%, calcined, casks	lb	.06¼–	06½
Potassium chlorate, powd	lb	07½–	.08
Potassium cyanide, drums	lb	.45 –	.50
Potassium, first sorts, cask	lb.	.08¼	.08½
Potassium hydroxide (caustic potash) drums	lb	07½–	09
Potassium iodide, cases	lb	3 65 –	3 75
Potassium nitrate, bbl.	lb	.06¼–	.07¼
Potassium permanganate, drums	lb.	.17½–	19
Potassium prussiate, red, casks	lb.	.65 –	67
Potassium prussiate, yellow, casks	lb.	35 –	35½
Salammoniac, white, gran., casks, imported	lb.	.06 –	06½
Salammoniac, white, gran., bbl., domestic	lb	.07½–	.07½
Gray, gran., casks	lb	08 –	.09
Salsoda, bbl	100 lb	1 20	1 40
Salt cake (bulk)	ton	26 00 –	28 00
Soda ash, light, 58% flat, bags, contract	100 lb	1.60 –	1 67
Soda ash, light, basis, 48%, bags, contract, f.o.b. wks.	100 lb.	1.20 –	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb	1 75 –	1 80
Soda ash, dense, bags, contract, basis 48%.	100 lb	1 17½–	1 20
Soda ash, dense, in bags, resale	100 lb	1 85 –	1.90
Soda, caustic, 76%, solid, drums, f.a.s.	100 lb.	3 22½–	3 35
Soda, caustic, basis 60%, wks., contract.	100 lb.	2 50 –	2.60
Soda, caustic, ground and flake, contracts	100 lb.	3 80 –	3.90
Soda, caustic, ground and flake, resale.	100 lb.	3.92½–	...
Sodium acetate, works, bags.	lb	05½–	.06½
Sodium bicarbonate, bbl	100 lb.	2 00 –	2 50
Sodium bichromate, casks.	lb.	.08½–	.09
Sodium bisulphate (niter cake)	ton	6.00 –	7.00
Sodium bisulphite, powd., U.S.P., bbl.	lb.	.04½–	.04½
Sodium chlorate, kegs	lb.	.06½–	.07
Sodium chloride	long ton	12.00 –	13.00
Sodium cyanide, cases	lb.	.20 –	.23
Sodium fluoride, bbl.	lb.	$0 09 –	$0 10½
Sodium hyposulphite, bbl.	lb.	$02½–	.03
Sodium nitrite, casks	lb	07½–	08½
Sodium peroxide, powd., cases	lb.	.28 –	.30
Sodium phosphate, dibasic, bbl	lb.	.03½–	.04
Sodium prussiate, yel. drums	lb.	.15 –	.16
Sodium salicylic, drums	lb.	.47 –	52
Sodium silicate (40°, drums)	100 lb.	.80 –	1.25
Sodium silicate (60°, drums)	100 lb.	2.00 –	2.25
Sodium sulphide, fused, 60-62% drums	lb.	.04½–	.04½
Sodium sulphite, crys., bbl	lb	03½–	03¾
Strontium nitrate, powd., bbl.	lb	.12½–	.13
Sulphur chloride, yel. drums	lb	04½–	05
Sulphur, crude	ton	18 00 –	20 00
At mine, bulk	ton	16 00 –	18 00
Sulphur, flour, bag	100 lb	2 25 –	2 35
Sulphur, roll, bag	100 lb.	2 00 –	2.10
Sulphur dioxide, liquid, cyl.	lb	08 –	08½
Talc—imported, bags	ton	30 00 –	40.00
Talc—domestic powd., bags.	ton	18.00 –	25.00
Tin bichloride, bbl.	lb.	.12½–	.13
Tin oxide, bbl	lb.	.48 –	
Tin crystals, bbl	lb.	.34½–	.35
Zinc carbonate, bags	lb.	.14 –	.14½
Zinc chloride, gran, bbl.	lb.	.06½–	.06¾
Zinc cyanide, drums.	lb.	.37 –	.38
Zinc oxide, lead free, bbl.	lb.	.08 –	.08½
5% lead sulphate, bags	lb	.07½–	...
10 to 35% lead sulphate, bags	lb.	.07 –	...
French, red seal, bags	lb.	.09¾–	...
French, green seal, bags	lb.	.10¾–	...
French, white seal, bbl	lb.	.12 –	...
Zinc sulphate, bbl.	100 lb.	2.50 –	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl.	lb.	$0.65 –	$0.80
Alpha-naphthol, ref., bbl	lb.	.75 –	.90
Alpha-naphthylamine, bbl	lb.	.35 –	37
Aniline oil, drums	lb.	.16½–	.16½
Aniline salts, bbl.	lb.	.23 –	.24
Anthracene, 80%, drums	lb.	.75 –	1.00
Anthracene, 80%, imp., drums, duty paid.	lb.	.70 –	.75
Anthraquinone, 25%, paste, drums	lb.	.70 –	.75
Benzaldehyde U.S.P., carboys	lb.	1.40 –	1.45
tech., drums	lb	.75	80
Benzene, pure, water-white, tanks and drums	gal.	.27 –	.32
Benzene, 90%, tanks & drums	gal.	.25 –	.30
Benzene, 90%, drums, resale.	gal.	.28 –	.32
Benzidine base, bbl.	lb.	.80 –	.85
Benzidine sulphate, bbl	lb.	.70 –	.75
Benzoic acid, U.S.P., kegs	lb.	.75 –	80
Benzoate of soda, U.S.P., bbl.	lb.	.57 –	.65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 –	...
Benzyl chloride, tech., drums	lb.	.30 –	.35
Beta-naphthol, tech., bbl	lb.	.22 –	.23
Beta-naphthylamine, tech.	lb.	.80 –	.90
Cresol, U.S.P., drums.	lb.	.25 –	.29
Ortho-cresol, drums	lb.	.26 –	.30
Cresylic acid, 97%, resale, drums	gal.	1 15 –	1.20
95-97%, drums, resale	gal.	1.10 –	
Dichlorbenzene, drums	lb.	.07 –	.09
Diethylaniline, drums	lb.	.50 –	.60
Dimethylaniline, drums	lb.	.42 –	.43
Dinitrobenzene, bbl.	lb.	.19 –	.20
Dinitroclorbenzene bbl	lb	.22 –	.23
Dinitronaphthalen, bbl.	lb.	.30 –	.32
Dinitrophenol, bbl	lb.	.35 –	.40
Dinitrotoluene, bbl	lb.	.20 –	.22
Dip oil, 25%, drums	gal.	.25 –	.30
Diphenylamine, bbl.	lb.	.50 –	.52
H-acid, bbl.	lb.	.80 –	.85
Meta-phenylenediamine, bbl.	lb	1.00 –	1.05
Michlers ketone, bbl	lb	3.00 –	3.50
Monochlorbenzene, drums	lb	.08 –	.10
Monoethylaniline, drums	lb.	.95 –	1.10
Naphthalene, flake, bbl.	lb.	.08¼–	.08¾
Naphthalene, balls, bbl.	lb.	.09 –	.09½
Naphthionate of soda, bbl.	lb.	.58 –	.65
Naphthionic acid, crude, bbl.	lb.	.55 –	.60
Nitrobenzene, drums	lb.	.10 –	.12
Nitro-naphthalene, bbl.	lb.	.30 –	.35
Nitro-toluene, drums	lb.	.15 –	.17
N-W acid, bbl.	lb.	1.25 –	1.30
Ortho-amidophenol, kegs	lb.	2.30 –	2.35
Ortho-dichlorbenzene, drums	lb.	.17 –	.20
Ortho-nitrophenol, bbl.	lb.	.90 –	.92
Ortho-nitrotoluene, drums	lb.	.10 –	.12
Ortho-toluidine, bbl.	lb.	.14 –	.15
Para-amidophenol, base, kegs	lb.	1.20 –	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 –	1.35
Para-dichlorbenzene, bbl.	lb.	.17 –	.20
Paranitroaniline, bbl.	lb.	.70 –	.75
Para-nitrotoluene, bbl.	lb.	.60 –	.65
Para-phenylenediamine, bbl.	lb.	1.45 –	1.50
Para-toluidine, bbl	lb.	.95 –	.98
Phthalic anhydride, bbl.	lb.	.35 –	.38
Phenol, U.S.P., drums	lb.	.48 –	.50
Picric acid, bbl.	lb.	.20 –	.22
Pyridine, dom., drums	gal.	nominal	

Pyridine, imp., drums	gal.	$2.50 - $2.75
Resorcinol, tech., kegs	lb.	1.50 - 1.60
Resorcinol, pure, kegs	lb.	2.25 - ...
R-salt, bbl.	lb.	.55 - .60
Salicylic acid, tech., bbl.	lb.	.37 - .42
Salicylic acid, U.S.P., bbl.	lb.	.40 - .45
Solvent naphtha, water-white, drums	gal.	.27 - .32
Crude, drums	gal.	.24 -
Sulphanilic acid, crude, bbl.	lb.	.18 - .20
Thiocarbanilide, kegs	lb.	.35 - .38
Toluidine, kegs	lb.	1.20 - 1.30
Toluidine, mixed, kegs	lb.	.30 - .35
Toluene, tank cars	gal.	.30 - .35
Toluene, drums	gal.	.35 - .40
Xylidines, drums	lb.	.47 - .49
Xylene, pure, drums	gal.	.75 - 1.00
Xylene, com., drums	gal.	.37 -
Xylene, com., tanks	gal.	.32

Naval Stores

Rosin B-D, bbl.	280 lb.	$5.90 -
Rosin E-I, bbl.	280 lb.	6.00 -
Rosin K-N, bbl.	280 lb.	6.20 -
Rosin W.G.-W.W., bbl.	280 lb.	6.50 - 7.50
Wood rosin, bbl.	280 lb.	6.00 - 6.10
Turpentine, spirits of, bbl.	gal.	1.03 - 1.04
Wood, steam dist., bbl.	gal.	.96 -
Wood, dest. dist., bbl.	gal.	.65 - .67
Pine tar pitch, bbl.	200 lb.	6.00
Tar, kiln burned, bbl.	500 lb.	- 13.00
Retort tar, bbl.	500 lb.	- 12.00
Rosin oil, first run, bbl.	gal.	.45 -
Rosin oil, second run, bbl.	gal.	.48 -
Rosin oil, third run, bbl.	gal.	.52 -
Pine oil, steam dist.	gal.	.75 -
Pine oil, pure, dest. dist.	gal.	.70
Pine tar oil, ref.	gal.	.48 -
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla.	gal.	.32 - .32½
Pine tar oil, double ref., bbl.	gal.	- .75
Pine tar, ref., thin, bbl.	gal.	- .25
Pinewood creosote, ref., bbl.	gal.	- .52

Animal Oils and Fats

Degras, bbl.	lb.	$0.03½ - $0.04½
Grease, yellow, bbl.	lb.	.06½ - .06½
Lard oil, Extra No. 1, bbl.	gal.	.90 - .92
Neatsfoot oil, 20 deg. bbl.	gal.	1.30 -
No. 1, bbl.	gal.	.92 - .94
Oleo Stearine		.09 -
Red oil, distilled, d.p. bbl.	lb.	.10½ - .10½
Saponified, bbl.	lb.	.10½ - .10½
Tallow, extra, loose	lb.	.07½
Tallow oil, acidless, bbl.	gal.	.94 - .96

Vegetable Oils

Castor oil, No. 3, bbl.	lb.	$0.14 -
Castor oil, No. 1, bbl.	lb.	.14½
Chinawood oil, bbl.	lb.	.26 - .28
Coconut oil, Ceylon, bbl.	lb.	.09½
Ceylon, tanks, N.Y.	lb.	.08½

Corn oil, crude, bbl.	lb.	.12½
Crude, tanks, (f.o.b. mill)	lb.	.09½
Cottonseed oil, crude (f.o.b. mill), tanks	lb.	.10
Summer yellow, bbl.	lb.	.12½ - .13
Winter yellow, bbl.	lb.	.13½ - .13½
Linseed oil, raw, car lots, bbl.	gal.	1.12 -
Raw, tank cars (dom.)	gal.	1.07
Boiled, cars, bbl. (dom.)	gal.	1.14
Olive oil, denatured, bbl.	gal.	1.10
Sulphur, (foots) bbl.	lb.	.08½ - .09
Palm, Lagos, casks	lb.	.07½ - .07½
Niger, casks	lb.	.07 - .07½
Palm kernel, bbl.	lb.	.08½ - .08½
Peanut oil, crude, tanks (mill)	lb.	.13 - .13½
Peanut oil, refined, bbl.	lb.	.16½ -
Perilla, bbl.	lb.	.15½ - .16
Rapeseed oil, refined, bbl.	gal.	.83 - .84
Rapeseed oil, blown, bbl.	gal.	.88 - .89
Sesame, bbl.	lb.	.11½ - .12
Soya bean (Manchurian), bbl.	lb.	.12½ - .12½
Tank, f.o.b. Pacific coast	lb.	.09½ - .10
Tank, (f.o.b. N.Y.)	lb.	.10½ - .10½

Fish Oils

Cod, Newfoundland, bbl.	gal.	$0.70 - $0.72
Menhaden, light pressed, bbl.	gal.	.76 -
White bleached, bbl.	gal.	.78 -
Blown, bbl.	gal.	.82 -
Crude, tanks (f.o.b. factory)	gal.	.50 -
Whale No. 1 crude, tanks, coast	lb.	
Winter, natural, bbl.	gal.	.76 - .78
Winter, bleached, bbl.	gal.	.79 - .80

Oil Cake and Meal

Coconut cake, bags	ton	$30.00 - $31.00
Copra, sun dried, bags, (c.i.f.)	lb.	.04½ - .05
Sun dried Pacific coast	lb.	.04½ - .04½
Cottonseed meal, f.o.b. mills	ton	38.00 -
Linseed cake, bags	ton	34.00 -
Linseed meal, bags	ton	36.00 -

Dye & Tanning Materials

Albumen, blood, bbl.	lb.	$0.45 - $0.50
Albumen, egg, tech., keg	lb.	.90 - .95
Cochineal, bags	lb.	.33 - .35
Cutch, Borneo, bales	lb.	.04½ - .05
Cutch, Rangoon, bales	lb.	.13 - .13½
Dextrine, corn, bags	100 lb.	3.69 - 4.01
Dextrine gum, bags	100 lb.	3.99 - 4.09
Divi-divi, bags	ton	38.00 - 39.00
Fustic, sticks	ton	30.00 - 35.00
Fustic, chips, bags	lb.	.04 - .05
Logwood, sticks	ton	26.00 - 30.00
Logwood, chips, bags	lb.	.02½ - .03½
Sumac, leaves, Sicily, bags	ton	70.00 - 72.00
Sumac, ground, bags	ton	$65.00 - $67.00
Sumac, domestic, bags	ton	40.00 - 42.00
Starch, corn, bags	100 lb.	2.97 - 3.07
Tapioca flour, bags	lb.	.06 - .06½

Extracts

Archil, conc., bbl.	lb.	$0.17 - $0.18
Chestnut, 25% tannin, tanks	lb.	.02 - .03
Divi-divi, 25% tannin, bbl.	lb.	.04 - .05
Fustic, crystals, bbl.	lb.	.20 - .22
Fustic, liquid, 42°, bbl.	lb.	.08 - .09
Gambier, liq., 25% tannin, bbl.	lb.	.08 - .09
Hematine crys., bbl.	lb.	.14 - .18
Hemlock, 25% tannin, bbl.	lb.	.04 - .05
Hypernic, solid, drums	lb.	.24 - .26
Hypernic, liquid, 51°, bbl.	lb.	.10 - .12
Logwood, crys., bbl.	lb.	.18 - .20
Logwood, liq., 51°, bbl.	lb.	.09 - .10
Quebracho, solid, 65% tannin, bbl.	lb.	.04½ - .05
Sumac, dom., 51°, bbl.	lb.	.06½ - .07

Dry Colors

Blacks—Carbongas, bags, f.o.b. works	lb.	$0.20 - $0.24
Lampblack, bbl.	lb.	.12 - .40
Mineral, bulk	ton	35.00 - 45.00
Blues—Bronze, bbl.	lb.	.55 - .60
Prussian, bbl.	lb.	.55 - .60
Ultramarine, bbl.	lb.	.08 - .35
Browns, Sienna, Ital., bbl.	lb.	.06 - .14
Sienna, Domestic, bbl.	lb.	.03½ - .04
Umber, Turkey, bbl.	lb.	.04 - .04½
Greens—Chrome, C.P. Light, bbl.	lb.	.32 - .34
Chrome, commercial, bbl.	lb.	.12 - .12½
Paris, bulk	lb.	.30 - .35
Reds, Carmine No. 40, tins	lb.	4.50 - 4.70
Oxide red, casks	lb.	.10 - .14
Para toner, kegs	lb.	1.00 - 1.10
Vermilion, English, bbl.	lb.	1.30 - 1.32
Yellow, Chrome, C.P. bbls.	lb.	.20 - .21
Ocher, French, casks	lb.	.02½ - .03

Waxes

Bayberry, bbl.	lb.	$0.30 - $0.32
Beeswax, crude, bags	lb.	.20 - .21
Beeswax, refined, light, bags	lb.	.32 - .34
Beeswax, pure white, cases	lb.	.40 - .41
Candelilla, bags	lb.	.20½ - .21½
Carnauba, No. 1, bags	lb.	.42 - .43
No. 2, North Country, bags	lb.	.23 - .23½
No. 3, North Country, bags	lb.	.18½ - .19
Japan, cases	lb.	.16 - .16½
Montan, crude, bags	lb.	.04½ - .04½
Paraffine, crude, match, 105-110 m.p.	lb.	.04 - .04½
Crude, scale 124-126 m.p., bags	lb.	.02½ - .03
Ref., 118-120 m.p., bags	lb.	.03 - .03½
Ref., 125 m.p., bags	lb.	.03½ - .03½
Ref., 128-130 m.p., bags	lb.	.03½ - .03½
Ref., 133-135 m.p., bags	lb.	.04½ - .04½
Ref., 135-137 m.p., bags	lb.	.05 - .05½
Stearic acid, sgle pressed, bags	lb.	.12½ - .12½
Double pressed, bags	lb.	.13 - .13½
Triple pressed, bags	lb.	.14½ - .14½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3.25 - $3.30
F.a.s. double bags	100 lb.	3.85 - 3.90
Blood, dried, bulk	unit	4.00 -
Bone, raw, 3 and 50, ground	ton	27.00 - 30.00
Fish scrap, dom., dried, wks.	unit	3.75 -
Nitrate of soda, bags	100 lb.	2.45 - 2.52½
Tankage, high grade, f.o.b. Chicago	unit	3.60 - 3.70
Phosphate rock, f.o.b. mines, Florida pebble 68-72%	ton	$4.00 - $4.50
Tennessee, 78-80%	ton	8.00 - 8.25
Potassium muriate, 80%, bags	ton	34.55 -
Potassium sulphate, bags basis 90%	ton	43.67 -
Double manure salt	ton	25.72 -
Kainit	ton	7.22 -

Crude Rubber

Para—Upriver fine	lb.	$0.28½ - $0.28½
Upriver coarse	lb.	.26 -
Upriver caucho ball	lb.	.26½ -
Plantation—First latex crepe	lb.	.28½ - .28½
Ribbed smoked sheets	lb.	.28½ - .28½
Brown crepe, thin, clean	lb.	.27 -
Amber crepe No. 1	lb.	.28 -

Gums

Copal, Congo, amber, bags	lb.	$0.12 - $0.13
East Indian, bold, bags	lb.	.23 - .23½
Manila, pale, bags	lb.	.20 - .20½
Pontinak, No. 1 bags	lb.	.20 - .20½
Damar, Batavia, cases	lb.	.27½ - .28½
Singapore, No. 1, cases	lb.	.34 - .35
Singapore, No. 2, cases	lb.	.22 - .23
Kauri, No. 1, cases	lb.	.65 - .67
Ordinary chips, cases	lb.	.20 - .22
Manjak, Barbados, bags	lb.	.09 - .09½

Shellac

Shellac, orange fine, bags	lb.	$0.61 -
Orange superfine, bags	lb.	.63 -
A. C. garnet, bags	lb.	nominal
Bleached, bonedry	lb.	.70 - .71
Bleached, fresh	lb.	.58 -
T. N., bags	lb.	.58 -

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$500.00 -
Asbestos, shingle, f.o.b., Quebec	sh. ton	$65.00 - $85.00
Asbestos, cement, f.o.b., Quebec	sh. ton	20.00 - 25.00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 - 20.00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13.00 - 15.00
Barytes, floated, f.o.b. St. Louis, bbl.	net ton	28.00 -
Barytes, crude f.o.b. mines, bulk	net ton	10.00 - 11.00
Casein, bbl., tech.	lb.	.17½ - .18½
China clay (kaolin) crude, f.o.b. Ga.	net ton	7.00 - 9.00
Washed, f.o.b. Ga.	net ton	8.00 - 9.00
Powd., f.o.b. Ga.	net ton	14.00 - 20.00
Crude f.o.b. Va.	net ton	8.00 - 12.00
Ground, f.o.b. Va.	net ton	14.00 - 20.00
Imp., lump, bulk	net ton	15.00 - 20.00
Imp., powd.	net ton	45.00 - 50.00
Feldspar, No. 1 pottery	long ton	6.00 - 7.00
No. 2 pottery	long ton	4.00 - 5.50
No. 1 soap	long ton	7.00 - 7.50
No. 1 Canadian, f.o.b. mill	long ton	20.00 - 22.00
Graphite, Ceylon, lump, first quality, bbl.	lb.	.06½ -
Ceylon, chip, bbl.	lb.	.05½ -
High grade amorphous crude	ton	15.00 - 35.00
Gum arabic, amber, sorts, bags	lb.	.14½ - .15
Gum tragacanth, sorts, bags	lb.	.48 - .56
No. 1, bags	lb.	1.50 - 1.60
Kieselguhr, f.o.b. Cal.	ton	40.00 - 42.00
F.o.b. N.Y.	ton	50.00 - 55.00
Magnesite, crude, f.o.b. Cal.	ton	14.00 - 15.00
Pumice stone, imp., casks	lb.	.03 - .05½
Dom., lump, bbl.	lb.	.05 - .05½
Dom., ground, bbl.	lb.	.06 - .07
Silica, glass sand, f.o.b. Ind.	ton	2.00 - 2.50
Silica, sand blast, f.o.b. Ind.	ton	2.50 - 5.00
Silica, amorphous, 250-mesh, f.o.b. Ill.	ton	17.00 - 17.50
Silica, bldg. sand, f.o.b. Pa.	ton	2.00 - 2.75
Soapstone, coarse, f.o.b. Vt., bags	ton	7.00 - 8.00
Talc, 200 mesh, f.o.b. Vt., bags	ton	6.50 - 9.00
Talc, 200 mesh, f.o.b. Ga., bags	ton	7.00 - 9.00
Talc, 200 mesh, f.o.b. Los Angeles, bags	ton	16.00 - 20.00

Mineral Oils

Crude, at Wells

Pennsylvania	bbl.	$3.25 - 3.50

Indiana	bbl.	1.98 -
Kansas and Oklahoma, 28 deg.	bbl.	1.30 -
California, 35 deg. and up	bbl.	1.04 -

Gasoline, Etc.

Motor gasoline, steel bbls.	gal.	$0.21½ -
Naphtha, V. M. & P. deod., steel bbls.	gal.	.20½ -
Kerosene, ref. tank wagon	gal.	.14 -
Bulk, W. W. export	gal.	.07 -
Lubricating oils:		
Cylinder, Penn., dark	gal.	.22 - .25
Bloomless, 30@31 grav.	gal.	.18½ - .20½
Paraffin, pale	gal.	.24 - .26
Spindle, 200, pale	gal.	.22 - .24
Petrolatum, amber, bbls.	lb.	.05 - .05½
Paraffine wax (see waxes)		

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	ton	$45-50
Chrome brick, f.o.b. Eastern shipping points	ton	50-52
Chrome cement, 40-50% Cr_2O_3	ton	23-27
40-45% Cr_2O_3, sacks, f.o.b. Eastern shipping points	ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Ky. wks.	1,000	40-46
2nd. quality, 9-in. shapes, f.o.b. wks.	1,000	36-41
Magnesite brick, 9-in. straight (f.o.b. wks.)	ton	65-68
9-in arches, wedges and keys	ton	80-85
Scraps and splits	ton	85
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48-50
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	48-50
F.o.b. Mt. Union, Pa.	1,000	42-44
Silicon carbide refract. brick, 9-in.	1,000	1,100.00

Ferro-Alloys

Ferrotitanium, 15-18% f.o.b. Niagara Falls, N.Y.	ton	$200.00 - $225.00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11½ - .11½
4-6% C	lb.	.12 - .13
Ferromanganese, 78-82% Mn, Atlantic seabd. duty paid	gr. ton	125.00 -
Spiegeleisen, 19-21% Mn	gr. ton	40.00 -
Ferromolybdenum, 50-60% Mo, per lb. Mo	lb.	2.00 - 2.50
Ferrosilicon, 10-15%	gr. ton	48.00 - 50.00
50%	gr. ton	95.00 -
75%	gr. ton	150.00 - 160.00

Ferrotungsten, 70-80%, per lb. of W	lb.	\$0.90 - \$0.95
Ferro-uranium, 35-50% of U, per lb. of U	lb.	6.00 - ....
Ferrovanadium, 30-40%, per lb. of V	lb.	3.50 - 3.75

Ores and Semi-finished Products

Bauxite, dom. crushed, dried, f.o.b. shipping points	ton	\$6.00 - \$9.00
Chrome ore Calif. concentrates, 50% min. Cr_2O_3	ton	22 00 - 23 00
C i f. Atlantic seaboard	ton	20 50 - 24 00
Coke, fdry., f.o b. ovens	ton	7 00 - 7 50
Coke, furnace, f o b ovens	ton	6 00 - 6.50
Fluorspar, gravel, f.o.b. mines' Illinois	ton	20 00 - 21 50
Ilmenite, 52% TiO_2	lb.	.01½ - .01¾
Manganese ore, 50% Mn, c i f. Atlantic seaport	unit	.33 - ....
Manganese ore, chemical (MnO_2)	ton	75 00 - 80 00
Molybdenite, 85% MoS_2, per lb. MoS_2, N Y.	lb	.65 - .70
Monazite, per unit of ThO_2, c i f, Atl. seaport	lb.	.06 - 08
Pyrites, Span., fines, c.i f. Atl seaport	unit	.11½ - .12
Pyrites, Span., furnace size, c i f. Atl seaport	unit	.11½ - .12

MUSKEGON HEIGHTS—The Stroh Aluminum Co., 232 Chene St., Detroit, has tentative plans under consideration for a new local plant. Application has been made to the Muskegon Board of Commerce for a suitable site The company is allied with the Stroh Castings Co

Missouri

ST LOUIS The Warren Steel Casting Co, 3400 Maury Ave, has preliminary plans under consideration for the rebuilding of the portion of its foundry destroyed by fire, May 23, with loss estimated at about \$42,000, including equipment.

New Hampshire

NASHUA - The Boston & Maine Railroad Co, North Station, Boston, Mass., will have plans prepared at once for the construction of a new chemical tie-treating plant on local site, comprising about 80 acres of land, recently acquired. Complete machinery will be installed for creosoting and kindred operations. The plant is estimated to cost close to \$100,000, with equipment.

New Jersey

TRENTON- The Trenton Flint & Spar Co., Academy and North Montgomery Sts., has filed plans for the erection of a new 1-story plant on Marian St., to be equipped for pulverizing, sorting, etc.

PHILLIPSBURG—Fire, May 29, destroyed a portion of the plant of the J. T. Baker Chemical Co. An official estimate of loss has not been announced It is planned to rebuild at an early date.

JERSEY CITY—Robert Griffin & Co., 151 West Side Ave., manufacturers of wall paper, have awarded a contract to W. H.

& F. W. Crane, Journal Square, for the erection of a new 2-story plant addition, 50x300 ft., on West Side Ave., estimated to cost approximately $100,000, including equipment. C. H. Ziegler, 75 Montgomery St., is architect.

NEWARK—The May Chemical Co., 204 Niagara St., manufacturer of chemicals, colors, etc., has acquired through the Bernard Trading Co., a holding company, property adjoining its plant at 200-202 Niagara St., 50x100 ft. It is planned to build an addition to the plant in the near future. Dr. Otto May is president.

New York

ROCHESTER—The F. B. Rae Co., foot of Ambrose St., manufacturer of oils, paints, etc., has preliminary plans under consideration for the rebuilding of the portion of its plant destroyed by fire, May 25, with loss estimated at $350,000, including buildings, equipment and stock.

TROY—The Manning Abrasive Co., Inc., 20 Murray St., New York, is considering the construction of a new plant in the vicinity of Troy for the manufacture of sandpaper and other abrasive products, estimated to cost close to $150,000, with machinery. The company is now operating a plant at Watervliet, N. Y.

Ohio

CHILLICOTHE—The Buckeye Tile Co., recently organized under Delaware laws with capital of $250,000, has plans for the construction of a new local plant for the manufacture of tile and kindred ceramic products. Seven kilns will be installed. The works will cost close to $75,000, including equipment. John C. Strayer, York, Pa., is president, and J. J. Carter, formerly connected with the Wheeling Tile Co., Wheeling, W. Va., plant superintendent.

CLEVELAND—The Master Builders Co., Union Bldg., Cleveland, manufacturer of special chemical-iron material for use in concrete reinforcement, has preliminary plans under consideration for the rebuilding of the portion of its plant destroyed by fire, May 22, with loss estimated at $100,000, including buildings and equipment.

SEBRING—The French China Co. is perfecting plans for enlargements in its plant, including the construction of new decorating kilns and the installation of additional equipment.

Pennsylvania

BENTLEY SPRINGS—New interests have acquired the plant and property of the Eagle Paper Mill, Bentley Springs, near Freeland. Plans are in progress for remodeling and improving the mill for considerable increase in production.

WASHINGTON—Fire, May 26, destroyed a portion of the plant of the Beaver Refining Co., Henderson Ave., manufacturer of refined petroleum products, with loss estimated at close to $500,000, including equipment. It is planned to rebuild at an early date.

NEW CASTLE—The Seiberling Rubber Co. has tentative plans under consideration for enlargements at its local plant to increase the capacity from 800 to about 2,500 tires per day. It is purposed to install additional equipment.

PHILADELPHIA—The Leather Products Co., 1150 Adams St., Frankford, has arranged for the removal of its plant to a new factory at Wayne Junction, where additional equipment will be provided for considerable increase in the manufacture of chemical leather products. A. S. Hull is president.

JENKINTOWN—The Farmastic Co., recently formed under Delaware laws with capital of $250,000, has construction in progress on a new local plant for the manufacture of paint and affiliated products. It is purposed to commence operations early in July. Martin R. Jacobs is president and J. D. Farber, secretary and treasurer.

NEW CASTLE—The Shenango Pottery Co. will make enlargements in its plant and install additional equipment for considerable increase in production. Three additional kilns will be built. The company has arranged for an increase in capital from $230,000 to $750,000 for expansion.

South Carolina

HONEA PATH—The Honea Path Oil Mill Co. has plans under consideration for the construction of a new cottonseed oil mill.

Tennessee

SIGNAL MOUNTAIN—The Signal Mountain Portland Cement Co. has work nearing completion on its new local cement manufacturing plant and plans to finish the machinery installation during July. The plant will represent an investment of close to $2,000,000. It will have a capacity for handling 12,000 bbl. of material a day.

COLORADO CITY—The Tubbock Cotton Oil Co. has work in progress on a new cottonseed oil mill, four-press type, estimated to cost about $200,000, including machinery. At a later date it is planned to increase the plant to an eight-press mill, doubling the initial output.

RANGER—The Baltic Gas Co. has plans nearing completion for the construction of a new gasoline-refining plant, estimated to cost close to $90,000, with equipment. R. W. Thomas, E. D. Finney and Charles Terrell head the company.

DALLAS—The Dallas Pottery Co. has acquired a tract of about 7½ acres of land in the Love Industrial Field, and plans for the erection of a new plant to cost about $75,000, including equipment. Work will be commenced at an early date. Taylor Jackson is general manager.

Virginia

CHINCOTEAGUE—The Assateague Fish, Oil & Fertilizer Co. has been reorganized and will succeed to the plant and business of the company of the same name. The new organization is capitalized at $560,000; it will make extensions and improvements at the fertilizer mill and plans to commence operations at an early date. William J. Highfield, Wilmington, Del., is president, and Edward W. Pyle, secretary and treasurer.

Washington

SEATTLE—The Campbell Oil Co., Shelby, Mont., represented by Ray M. Wardall and Winter S. Martin, L. C. Smith Bldg., Seattle, has tentative plans under consideration for the erection of a new oil-refining plant on site now being selected at Seattle, to be equipped for an initial daily output of about 1,000 bbl. per day.

West Virginia

WHEELING—The West Virginia Match Co., recently formed with a capital of $300,000, has plans nearing completion for the construction of a new local plant estimated to cost in excess of $100,000 including machinery. A site has been selected.

New Companies

ST. LOUIS LITHOPONE CO., St. Louis, Mo., lithopone and chemical products, $350,000. Incorporators: Emmet C. Carter and E. A. Giblin, both of St. Louis.

FULTON CHEMICAL WORKS, INC., Brooklyn, N. Y., chemicals and chemical byproducts, $50,000. Incorporators: R. E. Slayton, F. S. Johnson and M. W. Lennon. Representative: Caldwell & Polhemus, 50 Church St., New York.

CHAPMAN OIL & REFINING CO., Room 1121, 29 South La Salle St., Chicago, Ill., refined oil products, $10,000. Incorporators: Ray C. Chapman, W. I. Power and Theodore C. Kretzman.

JOHN M. CARRECABE, INC., Chelsea, Mass.; fiberboard, leatherboard and kindred products, $70,000. A. L. Carrecabe, Swampscott, Mass., president and treasurer, and John A. Carrecabe, vice-president.

GUMITE CO., INC., Jersey City, N. J.; paints and varnishes, $100,000. Incorporators: Alfred O. Kellogg, Frank B. Vermilya, and John J. Field, 3d, 1 Union St., Jersey City. The last noted is representative.

AMALGAMATED RUBBER CO., Akron, O., rubber products, $10,000. Incorporators: Arthur L. and Edwin C. Abt, both of Akron.

PINKHAM CHEMICAL CORP., Brooklyn, N. Y.; chemicals and chemical byproducts, $10,000. Incorporators: M. M. Siegel, S. M. Louis and A. E. Rosenberg. Representative: G. H. Curtis, Jr., 51 Chambers St., New York.

RICHARD HAWORTH, INC., Providence, R. I., chemicals and chemical byproducts; $25,000. Incorporators: Harold A. Weaver, Edward C. Stiness and Richard Haworth, 130 Fountain St., Providence. The last noted is representative.

MOTORKOOL OIL CO., Wilmington, Del.; refined petroleum products; $500,000. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

LETTERMAN RUBBER WORKS, INC., San Antonio, Tex.; rubber products; $30,000. Incorporators: J. H. and M. W. Letterman, and J. T. Meyers, all of San Antonio.

NEWMAN OIL CO., Okmulgee, Okla.; refined oil products; $600,000. Incorporators: William C. and Thomas A. Newman, and Dwight Richardson, all of Okmulgee.

LARKRESEN CHEMICAL WORKS, INC., Wilmington, Del.; chemicals and chemical byproducts; $300,000. Representative: Colonial Charter Co., Ford Bldg., Wilmington.

GORDON CHEMICAL CO., INC., Foxboro, Mass.; chemicals and chemical byproducts; $250,000. Lewis Marks is president; and Nathan Haffer, 80 Green St., Boston, Mass., treasurer and representative.

J. M. HUBER, INC., West 2nd St. and the Hudson Boulevard, Jersey City, N. J.; printing and other inks, etc.; $500,000. Incorporators: Joseph M. Huber, Hans W. Huber and Walter Gundlach.

INDUSTRIAL OIL CO., INC., East Providence, R. I.; refined oils; $50,000. Incorporators: W. S. Canton, Simon Norman and John W. Canton, Jr., 80 Ivy St., Providence. The last noted is representative.

LLOYD & KLAPP, INC., Philadelphia, Pa.; soap products; $10,000. Edward M. K. Klapp, 1716 Spruce St., Philadelphia, is treasurer and representative.

PITTSBURGH POWDER & SUPPLY CO., Pittsburgh, Pa.; explosives and powder, being organized under state laws, application for a charter will be made on June 11. Incorporators: Charles G. Lane, Jr., John B. Nicklas, Jr., and Leonard Balter. Representative: Roland A. McCrady, 1130 Park Bldg., Pittsburgh.

RUBBERSTONE FLOORING CORP., New York, N. Y.; composition rubber products; $50,000. Incorporators: J. Schede and G. C. Hannam. Representative: J. J. Nolan, 25 Broad St.

BASTROP GLASS CO., Winchester, Ind.; glass products; $100,000. Incorporators: Charles W. Bowman, Stuart Pierce and James H. Moroney, all of Winchester.

CHAMELEON CO., New York, N. Y.; paints and varnishes, $10,000. Incorporators: R. W. Cramer, W. J. Labhardt and W. J. Shore. Representative: Olney & Comstock, 68 William St., New York.

BRILLIANT GLASS CO., Paterson, N. J.; glass products; $25,000. Incorporators: John E. O'Connor, Franklin L. and Leroy F. Duke, 193 Ellison St., Paterson. The last noted is representative.

Opportunities in the Foreign Trade

Parties interested in any of the following opportunities may obtain all available information from the Bureau of Foreign and Domestic Commerce at Washington or from any district office of the bureau. The number placed after the opportunity must be given for the purpose of identification.

ACIDS, SEBACIC. Stuttgart, Germany. Purchase.—6603.

AMMONIA, ANHYDROUS. Progreso, Mexico. Agency.—6637.

BORAX. Berlin, Germany. Purchase.—6596.

CHEMICALS. Goteborg, Sweden. Agency.—6598.

CHEMICALS. Progreso, Mexico. Purchase and Agency.—6599.

BLEACHING CHEMICALS. Bilbao, Spain. Purchase.—6606.

CHLORINE. Goteborg, Sweden. Agency.—6708.

DYESTUFFS. Goteborg, Sweden. Agency.—6598.

GLUE, BONE AND LEATHER. Basel, Switzerland. Agency.—6638.

INSECTICIDES. Bordeaux, France. Agency.—6605.

PAINTS, MOTOR CAR. East London, South Africa. Purchase.—6595.

PARAFFIN. Stuttgart, Germany. Purchase.—6601.

ROSIN. Stuttgart, Germany. Agency.—6598.

ROSIN. Ruzomberok, Czechoslovakia. Purchase.—6604.

SODAS. Goteborg, Sweden. Agency.—6598.

SODAS, caustic, bichromate of potassium, bichromate of soda, and chrome alum. Berlin, Germany. Purchase.—6708.

SODIUM SULPHATE. Goteborg, Sweden. Agency.—6598.

SULPHUR. Goteborg, Sweden. Agency.—6598.

TAR AND PITCH. Bordeaux, France. Agency.—6622.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 — New York, June 18, 1923 — *Number* 21

Skating on Thin Ice

SLIGHTLY more than a year ago the correspondence between Secretary HOOVER and the Attorney-General resulted in a list of permissible and legal trade association activities. One statement therein, which later developments have served to emphasize, might have been liberally interpreted as follows: "Beware of the open-price scheme! On the surface it may seem legally feasible, but potentially it's dangerous business." That warning still holds. And another pillar was added to its support when the Supreme Court in its decision on June 4 against the linseed oil associates held that "their manifest purpose was to defeat the Sherman act without subjecting themselves to its penalties." If there has been any shadow of doubt in the mind of the conscientious trade association executive regarding the ethics of the open-price plan, this decision should forever dispel it.

It is significant that the warning in the Hoover-Daugherty correspondence was sounded in spite of the fact that Judge CARPENTER in the District Court at Chicago had already refused the government's request for an injunction against the Armstrong Bureau of Related Industries. The lower tribunal held that there was no actual restraint of trade and therefore no violation of the Sherman act, but the decision indicated the illegal potentialities of the organization. Apparently Mr. HOOVER either judged this opinion too frail to support a legitimate trade association activity or even at that time he saw how clearly the linseed decision was foreshadowed by the Supreme Court's stand against the open prices of the Hardwood Manufacturers' Association. It has since been pointed out that only a very small but conspicuous minority of the trade associations has fostered the open-price scheme. Probably 98 per cent of the commercial organizations of the country have acted in the public interest, while a meager 2 per cent have brought the whole into disrepute. We should not lose sight, however, of the fact that the trade organization is not the only guilty party.

The operations of the linseed associates, as far as the original bill of complaint shows, were always free and above board. Their strict rules for adherence to the "open competition plan" were obviously framed for the single purpose of maintaining uniform prices and a stable market, but at no time was there evidence of connivance or secret conspiracy at price fixing. That supposedly competing firms in more than one line of industry are actually fixing prices under cover is a matter of general belief, if not common knowledge. Nearly everyone has observed the fact that price changes may be announced simultaneously by all of the firms in a single industry. Sometimes even the wording of these announcements is strikingly similar; once we noted the peculiar coincidence that two of them received in the same mail included the same typographical error. The fact that many of these practices have been carried on unmolested for so long may have given some of these firms a false idea of security. They should recognize, however, that they are skating on thin ice and that sooner or later their schemes are certain to meet with disaster.

Once the friends of honest business and the supporters of the many constructive and useful activities of the trade association are aroused they are going to see that the government's continued warnings do not longer go unheeded.

Messrs. Gary et Al. Are Misinformed

A GREAT AMOUNT of public interest—judging from newspaper and magazine comment—has been excited by the report of the American Iron and Steel Institute committee on the proposed total elimination of the 12-hour day. It has even been asserted that the gentlemen who signed the report, Messrs. GARY, BLOCK, BURDEN, CAMPBELL, DINKEY, FARREL, GRACE, KING and TOPPINGS, do not believe what they signed when they say that the 12-hour day has not of itself been an injury to the employees, either physically, mentally or morally.

Now we haven't any sympathy for the 12-hour day. We have worked the long turn in the hottest part of a steel mill in the hottest of summer. In the remembrance of those days and nights, we are quite sure we should never have signed that report, even in the interest of harmony. However, that is no reason for doubting that the gentlemen who did sign it are absolutely sincere and believe what it sets forth. Furthermore, we do not hesitate to say that before the present situation can be remedied, it is absolutely necessary for the "reformers" to recognize the fact that the real men in the industry would not tolerate any condition which they knew was sapping their workers—no matter what the dividend situation or profit and loss account might be.

The trouble is they do not know! They get the basis for their opinion from officials, welfare worker, industrial investigators, or common spies, all "insiders." Little of this so-called "information" is in turn based on sincere, impartial investigation by a person who has risen from the ranks of the night shift, or even capable of imagining himself in the worker's job or herself in the wife's shoes. Outside investigators, strangely enough, are resented as meddling busybodies. And for this reason it is obviously impossible to convert the Iron and Steel Institute committee to the 8-hour day until

its members actually get the real information and from the inside.

How this may be done is difficult to say. Perhaps it would not be too much to suggest that Mr. GARY, for instance, should choose some rising young executive in the Carnegie Steel Co. of strapping physique who could stand the gaff, give him the job of furnace man's helper, require him to lose his identity for 6 months and live on his wages among his fellow workmen.

Then Mr. GARY would get a new basis for opinion—and from the inside!

An Integrated Society Convention

THE recent spring meeting of the Taylor Society was one of the most enjoyable affairs of this nature that it has ever been our fortune to attend. One came away from this convention stimulated—with a feeling that something of true worth had taken place in which it was a privilege to participate. Comparing this feeling with the reactions caused by many gatherings of a like nature, one is moved to question wherein the difference lay. The usual feeling one takes away from such a meeting is of a mind in chaos, overcrowded with a heterogeneous mass of ill-digested facts.

The difference is just this, and it is one that many other technical societies could well mark: The Taylor Society's program was a unit. It was composed of different subjects—true; but each of these subjects was so chosen that it threw a searchlight beam on the main topic. By the discussion of a series of closely coordinated parts of the management problem its significance to industry was placed in a clearer and better light for all who attended.

Turning Refuse Into Money

THE FORWARD MARCH of technology prompts an occasional stock-taking of current terms. In the Chicago packing plants, we are told, all but the squeal is utilized; there is no waste. The refuse of today is the raw material of tomorrow. Hence one is forced to admit that the term "utilization of waste" is a misnomer, because the process or processes involved have become an integral part of industrial operation. The ideal manufacturing plant discards nothing; there is no refuse to throw away.

The scientist and his confrère, the expert technologist, delight to "make a job" of anything; and in this respect it is pertinent to review the profound influence of chemical engineering in recent years on the completeness of utilization of raw material or the byproducts of industry, no matter of what kind. The field for invention and initiative has been extensive, and advantage has been taken of its potentialities by a Californian corporation, headed by STANLEY HILLER, who appears to have an unusually keen sense of the economics of industrial effort and the latent value of what is usually considered as refuse. His researches and the practical application of his ideas on the manufacture of valuable byproducts from fruit pits during the war led to the establishment of an industry of no small proportions in the West. Concurrently, a study of conditions in the canning industry suggested an investigation into the losses of valuable liquors, with the result that he developed a unit plant, which collects and treats and clarifies what was previously thrown away, thus adding appreciably to the profits of the undertaking.

Fish curing and marketing has assumed immense proportions, especially in the Pacific Coast region. An idea of its importance may be gathered by considering the potential value of the material that has been discarded as valueless—the heads, tails and entrails—amounting to about 35 per cent of the weight of the catch. Mr. HILLER has developed a neat and compact treater, in which such refuse is chopped, cooked, deprived of oil, dried and ground. It is then sold as a chicken feed or fertilizer material. The oil recovered finds a ready market for a large number of purposes.

It's the little things that count. The scientifically complete utilization of all the raw material that Nature has provided, as well as of the residues and byproducts of normal manufacturing processes, indicates that we may be entering a new phase of industrial efficiency. The ability to apply such refinements in a practicable manner emphasizes the importance of large-scale operations and the value of technical control of the highest standard. Mr. HILLER'S successful work on the coast suggests another grouping of engineers—those who specialize in the work of turning waste products into assets of dividend value.

The Technical Man And His Job

NOTHING strikes nearer home to the technical man than a discussion of his job and his good relations with his employer. While he may be concerned primarily with his own efforts to improve his individual status, nevertheless anything that affects the standing of his profession is bound to have his attention. It is, therefore, to a peculiarly receptive audience that one of our readers has addressed the letter on page 1081 of this issue, which bears the title: "Is There an Agreement Against Technology?" He describes a condition which, if at all prevalent, would have a most unfavorable reaction on the chemical profession.

We believe it safe to say, however, that fortunately only a small minority of our manufacturers are a party to this "gentlemen's agreement" not to engage a technical expert who has left the employ of a competitor. The apparent effect of such a vicious practice would be to enable the manufacturer to carry on research up to a point where he has improved his product and established economic production and then to sit safely by and take his profits without fear of competition. A short-sighted policy, to be sure, but one likely to attract the opportunist. The effect on the technical man, on the other hand, would be to enslave him in his present position, or, if he loses that, force him into a different line of work in order to gain his livelihood. By thus narrowing the market in which the technical man can sell his special abilities, this practice takes away the incentive that makes for really worth-while research.

A somewhat parallel situation exists in the case of the unfair contracts which a few employers still exact from their technical men. These coercive contracts, entirely unilateral in character, would claim as the manufacturer's property all of the knowledge and experience gained by the technical man during the term of his employment. In spite of the fact that the courts have been called upon to iron out some of these difficulties and have succeeded in establishing some fairly definite

precedents, the practice still persists and these oppressive compacts are constantly held over the heads of some of our technical men.

The contract evil as well as the employing agreements stressed by our correspondent will not be corrected as long as the technical men submit to these injustices. There must be a more general recognition of the chemical and engineering professions and the chemist and engineer must win for themselves the same respect and trust that are now accorded the legal and medical professions. The responsibility for bringing about these changes is in the hands of the technical men themselves. Our reader's protest is a step in that direction.

The Flat Tire Of Industry

NOT LONG AGO an acquaintance said that finance was the flat tire of industry. This may sound like a rather flippant thought, but it was really a headline to call attention to the very sound truths lined up beneath it. It is perhaps too often the case that those industries with banking control are the most poorly managed and the least integrated.

This was the thought in our acquaintance's mind when he made that remark. He, like most of us, had seen the operating and the distribution departments of a manufacturing plant formulate the best of plans, more often than not with the full cognizance of the banking control, only to have the whole structure overturned at some later date for a purely financial reason. And he knew that in plants where the control lay in the plant and not in the bank, plans were made and carried through with respect to industrial, not financial, considerations.

But this wrecking of plans need not occur. Does not all modern industry base its plans on the plant budget? Suppose, then, that the banking control sits in on the budget making and then holds to the budget made. That's good financial practice as well as good industrial practice. And if such a course is followed, don't you think that the one-time flat tire will be reinflated—a sound wheel once again for our industrial machine?

Sizing Up The New Graduate

INDUSTRY has little concern with the "sweet girl graduate" of June, but in the large group of technical and scientific men now leaving our colleges and universities the chemical engineering industries do find each year a new source of inspiration and an ever new set of problems.

The young man upon graduation often feels that his scholastic record will of itself mean much. In a sense this is true, although industry also has other bases of judgment. And even the professors who have for 4 years consistently drilled into the young man the importance of high scholastic standing appreciate how many other factors must enter into the appraisal of his service value. This view is conspicuously apparent in an employment qualification record used by the department of chemistry at the University of Wisconsin. This record serves to assist the department head in answering requests from industry for young men of promise and in turn aids the graduates in obtaining work for which they are particularly qualified.

This record of qualifications cites twelve factors which form the background for the confidential estimate made by the faculty committee for each individual graduate. Integrity, quite properly, is the first requirement. It is followed in turn by personality, application, initiative, personal appearance, health, habits, attitude toward work, and co-operative spirit. Not until the tenth item in this estimate does one find the entry "scholastic record"; and it is followed only by two items of rather doubtful value—namely, "probable success" and "experience." This should be a most striking evidence to the young man that many factors enter into his rating as a prospective member of the profession in addition to the class standing, on which so much emphasis is placed during his collegiate experience.

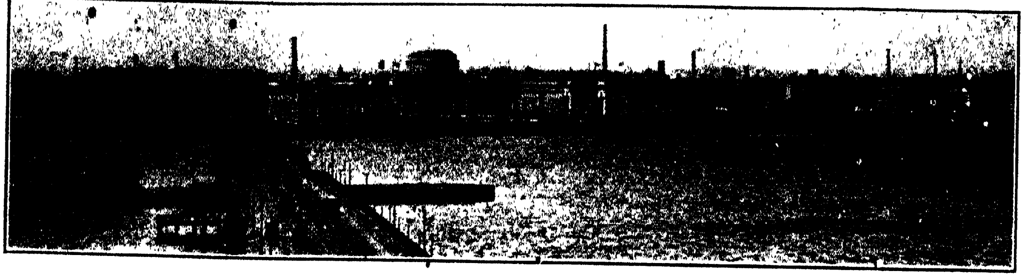
Breaking Him In

BUT there is another side to the case. Industry is confronted with a responsibility to the young men that come to it fresh from college filled with enthusiasm and ambition. Many if not most of them are ambitious beyond their powers of immediate accomplishment. It is of greatest importance that this ambition be curbed and this enthusiasm be directed into useful channels, although, of course, without the destruction of either.

One employer of our acquaintance has a course of cadet training for the young men whom he employs fresh from college. For a time at least most firms must use these youngsters in more or less routine fashion as aids in the various branches of the business. Moreover, it is commonly if not generally necessary to try them out in several departments before final judgment can be reached as to their place of greatest promise and usefulness.

In this post-graduate service the manager who is responsible for supervision of the young men must be peculiarly tactful or he will unwittingly destroy a most valuable asset—that of loyalty and enthusiasm for the organization as a whole. One instance, where serious results almost came to pass through misunderstanding, affords excellent warning to all employers. In that case a young man splendidly trained and of fine personality was made a cadet engineer in a large corporation of national scope. He was moved about from one department to another at frequent intervals and finally he became thoroughly discouraged. This happened because, as he puts it, he was never left alone long enough to do anything by himself. As soon as he found out what the particular job meant he was moved on to something else. The whole trouble lay in the fact that the young man did not understand the purpose of the movements. He thought they resulted from dissatisfaction with the service that he rendered, whereas, as a matter of fact, the very frequency with which he was moved was the best evidence he could get of the appreciation of the promptness with which he grasped each new situation. He was simply being given an opportunity to learn many phases of the business before being assigned his own particular niche to fill.

Industry has a responsibility in the training of these new hands. If by co-operation and understanding the management and the inexperienced apprentice can work together during this trying period, the results are bound to be of mutual value and satisfaction.



An Engineering Inaugural

Memorable in Itself, but Even More Memorable Because of the Great Composite Expression of the Faith of the Engineer

THE inauguration of Samuel Wesley Stratton as president of the Massachusetts Institute of Technology was more than an important academic event. It had greater significance than the induction of a strong proper leader as head of a great engineering school. It marked the expression of a faith that was vigorous, indomitable, inspiring. It was the challenge of the engineer for progress and peace.

This keynote found expression from many tongues. Dr. Stratton himself in his inaugural address selected as his text the famous line from Pliny's "Natural History, "*Alia initia e fine*. This he translated most happily, "Every finish marks a fresh start." The phrase, most appropriately carved in the office of the president at the Institute, represents perfectly the progress of science in general, and with it as a pointer Dr. Stratton painted a vivid picture of the effect of science on the evolution of the great industries of today steam transportation, electric power, the automobile, aeronautics, electric communication. Step by step the engineer has forged ahead from the beginnings that now seem ludicrous, aided by the chemist, the physicist and the mathematician, until the present industrial perfection has been achieved. And this perfection is but a beginning, for *alia initia e fine* is not a mere catch phrase. It is in the blood of the engineer.

Before Dr. Stratton's inaugural address many distinguished men, representing many phases of contact between the president and the Institute and commemorating his achievements as creator and head of the Bureau of Standards, brought messages of greeting. Through them all rang a note of confidence confidence that with men like Stratton in schools like the Institute the engineers of the future will be equipped to lead this nation and the world through paths of safety and progress.

A distinguished engineer, Prof. C.-E. A. Winslow of Yale, speaking for the alumni of the Institute, has given inspiring expression. "To us alumni of the Institute, the essential thing about the Institute, the thing that we hold so dear, is the spirit of science.

We want that spirit to have, through the work of the Institute and its alumni, the widest possible fruition. The problems of the purely material universe have been very largely solved during the past century. The great problems of the next century are of a different nature. They are problems of human relationship.

"The things that are wrong in the world today are the relationships between classes and the relationships between nations, and those difficulties are, I believe, to be solved by the spirit of applied science. That spirit means, first of all, honesty—intellectual honesty in facing the facts of any given situation. We do not build bridges by the methods of Coué. We calculate the stresses and the strains, and we attempt, as closely as possible, to visualize the load that bridge will have to bear. We need that spirit in dealing with these less tangible things. And when we have faced the facts as they are, we need then the courage and the confidence with which the engineer deals with his problems.

"If, as representing the alumni this morning, I have any wish for this Institute which Dr. Stratton is to carry on, it is that the young men who come here may fully realize the potency of this talisman of the scientific spirit, that they may not be merely engineers but citizens, and citizens not merely of America but of the world. And thus the torch which Dr. Stratton takes up today from the unseen hands of Maclaurin and Walker and Rogers may illumine all the dark places along that difficult road which leads onward—a world of order and of progress and of peace."

One more message to round out the picture! John Campbell Merriam, president of the Carnegie Institution of Washington, brought clearly to the front the responsibility of educators to develop in men a type of thinking that shall be free from prejudice and illusion and that shall be satisfied only with truth—truth, which, Swinburn says, "looks into the pit of hell and is not afraid."

"If this great country is to succeed in the continuing organization of its economic and political relations, it will be on the basis of clearly substantiated facts interpreted by a philosophy that expresses the true laws operating in human conduct. It is only by education in the kind of straight, clear, fearless thinking that characterizes the work of the scholar and investigator—plus the unselfish determination to accept facts where we find them—that we can keep on the upward path."

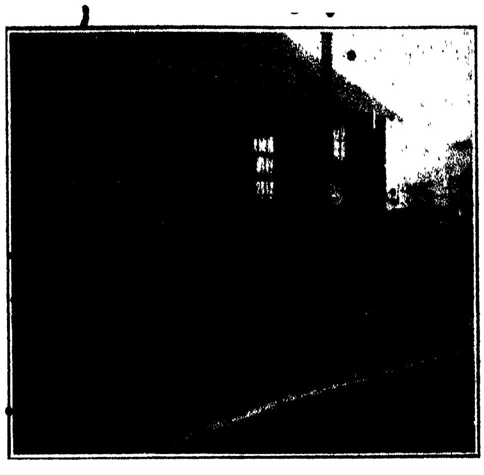
Samuel Wesley Stratton

Inaugurated as president of the Massachusetts Institute of Technology on June 11. As creator and head of the national Bureau of Standards, Dr. Stratton has won for himself an enviable position among the technologists and scientists of the world.

How the Railless Railroad *Solves the Unskilled Labor Problem*

BY MATTHEW WILLIAM POTTS
Consulting Engineer, New York City

Tractor and trailer transportation eliminates man-handling around the plant. It gives the advantage of hauling long trains without the necessity of following any given path.



Hauling barrels loaded on trailers over wooden runways. Concrete runways are a better investment, as they eliminate considerable maintenance troubles

IN the daily newspapers and technical publications of the country we read about the present shortage of cheap labor needed to perform the manual work of handling materials in various industries. Executives seem to agree that the 3 per cent immigration law must be raised in order to supply more manual laborers. How many of these same executives have given serious consideration to the use of material-handling equipment as a means of providing the necessary power to move materials in industries?

Man-power is a deceptively expensive luxury. Chinese coolies laboring for a few cents a day cannot develop power as cheaply as the American motor of either electric or gasoline drive. American mechanical power costs only a fraction of Chinese coolie-power. In addition, the use of this mechanical power increases the efficiency of the plant, because it is not subject to labor turnover.

In spite of this truth, there are still thousands of individual companies whose executives extravagantly employ man-power for the internal handling of incoming and outgoing freight, raw materials, parts and finished products. In addition to wasting needed man-power, these companies, almost without exception, are showing too high operating cost and too narrow profit margin.

The man on the hand or push truck and the gang carrying a load by hand—whether in industrial plant, storage yard, warehouse, freight platform, passenger-terminal or pier-shed—are heavy penalties on profits. Power does the job more cheaply.

The shrewd executive, seeking economy or cheap labor, can adopt few better tactics than to work out a way to apply tractors and trailers to his material-handling problems. Haulage is the backbone of virtually every industry. Unless raw materials, parts, finished products, supplies and freight move smoothly and on schedule to the point of need, the whole operating schedule breaks down, with an expensive waste due to labor time, idle equipment and all the far-reaching effects resulting from any upset of routine.

Is the solution of this labor shortage to be found in allowing more immigrants to enter the country? No. Why? Because the second generation of these immigrants are not satisfied to be common laborers; they have been educated in our public schools and they imbibe the same ideas that our own native children do and they desire to be in the skilled and not the unskilled labor class. Even the newcomers won't stay unskilled long.

HOW THE TRACTOR HELPS

The answer to the labor shortage is not a change in the laws that will mean only a temporary solution, but more extensive use of labor-saving devices (a better name would be labor-conserving devices) and machines to do the work of common labor. When we had a shortage in the field of skilled mechanics the development of automatic machines to do the work was speeded up. The same is true of the farm labor shortage, which was met by a more extensive use of farm machinery.

To make a mere play of words and to offer no concrete evidence in any discussion, especially in one so important as the present immigration question, is not productive of constructive improvements. For this reason I have taken the subject of tractors and trailers to illustrate the results that can be obtained by the more extensive use of material-handling equipment in industries and to point out how common labor can be obtained cheaper, quicker and better by installing this equipment than by changing the present 3 per cent immigration law.

Assuming 10 tons as a tractor load, a single machine replaces 40 hand-truckers handling 500 lb. each. By proper routing, with a drop-and-pick-up system of trailer-trains, a tractor can be kept almost continuously in action under load. Given the proper application, the tractor is the greatest labor conserver in the industrial vehicle family. Each tractor may be provided with three trains of trailers, ranging from five to ten trailers in length; thus all idle time in loading and unloading is consumed by the trailers only, the tractor uncoupling and passing on to the next job.

The tractor-trailer methods are frequently called "railless railroads" in order to differentiate between the original industrial railroad, which required rails on which to operate, and the present system of industrial railroads, which operate without rails. The feature of operating without being confined to one set line of travel has done much to bring about the great savings in money, time and space that can be effected by installing tractors and trailers. The constant changes in

methods of production make it imperative for the industrial transportation system to be adaptable quickly to new routes and conditions without incurring loss of time or additional money expenditure. As the electric or the gasoline tractor and its train of trailers can change its route at a moment's notice, it has all the advantages obtained by hauling long trains of materials, but none of the disadvantages caused by being confined to a given track or route which cannot be deviated from at will.

The term "railroad" is retained because the tractor-trailer equipment is in many ways similar to the equipment used on the steam railroads. First, we have the tractor, which is really the locomotive. Second, we have the trailers, which represent the cars and of which there are many styles and types to meet the need of the materials to be handled and the road conditions. Third, if the system is to operate successfully in any large plant, it is necessary to have a dispatch system and a centralized control of all equipment. Installing an industrial transportation system is not a hit-or-miss proposition, but is one that requires considerable thought on the original installation and close attention to the operating details.

Advantages of Using Tractors

Some of the advantages obtained by the use of a tractor-trailer system of industrial transportation, when compared to manual-handling, are:

1. Reduced number of men on the payroll.
2. Cheaper operating costs.
3. Quicker and better deliveries of materials between operations.
4. Complete co-operation between departments.
5. Increased production.
6. Reduction of labor troubles.
7. Reduction in labor turnover.
8. Reduction in amount of materials and parts damaged in transfer from operation to operation.
9. Better working conditions.
10. There are numerous others, such as assisting in distributing costs of handling by departments instead of placing it as an overhead item, providing a means of checking up the weak spots in the organization, etc.

The number of advantages depends upon the amount of attention paid to the system and the human element which operates it. By this I mean that if the system is operated with a common laborer as its directing head the results will not be as gratifying as if an intelligent and able man were placed in charge. Few railroads are operated by their common labor, and this same rule should apply to the tractor-trailer railroad in industry.

The writer has often analyzed the transportation problems of plants, with a view to improving the present methods of handling materials. Quite often it has been recommended that a tractor-trailer system be installed. If no equipment but common stevedore hand trucks are being used in the plant, it frequently necessitates the purchase of considerable new equipment. Many times the recommendation has been turned down because the executive did not know what it was costing him to handle materials with his present equipment and he did not take sufficient interest to have his own force find out the cost or wish to permit an outsider to determine it for him.

In other instances the present costs have been determined, but the initial investment has appeared too large; and the difficulty of obtaining such a large appropriation has deferred the installation of the system. It is now my practice, and I strongly recommend this method of procedure to salesmen and executives, to take one step of the problem at a time and segregate it so that after its successful solution it will be possible to take the next step without having to alter the first.

This method necessitates making a complete study of the problem and laying down a definite program. Gradual development will always prove the soundness of the complete system. The first step is to make a layout of the plant, showing all the points where it is necessary to deliver and pick up materials. The second step should be to analyze this layout to determine where the strategic points really are—in other words, where the natural flow of materials comes together. In this way it is often possible to make slight alterations in the delivery and pick-up points so as to save considerable time on each tractor trip and to cut down the length of haul. This new layout can immediately be put into service with the present equipment and it will automatically prove itself.

It is often necessary when first installing tractor-trailer systems to build up a "right of way" for the trains. This leads to the formation of a "maintenance of way" crew which will later form the nucleus of the transportation department. The building of

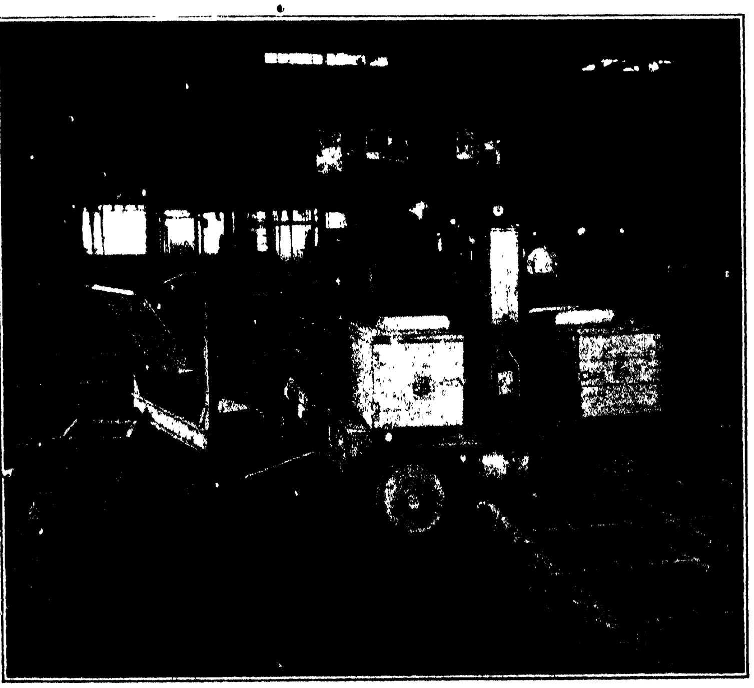


Fig. 1—Electric tractor hauling fifth wheel trailer over rough earth floor of foundry.

the right of way frequently saves money by making immediate improvements in the general yard condition, eliminating delays due to the truckers getting stuck and other familiar causes that lead to expense.

After the "right of way" is established one tractor and twelve trailers will form a good combination for the first purchase of equipment. This equipment in actual operation will decide what additional equipment should be purchased. Again the similarity of the tractor-trailer system to the common freight-handling railroad becomes apparent. Each tractor unit must be supplied with at least a 12 to 1 ratio of trailers if it is to be operated economically and efficiently. This is like supplying the railroad locomotive with cars. The type of trailers should be standardized as to wheels, bearings and connecting hitch; but the superstructure or frame can be made to suit the materials to be handled. There is so much lining up of trainloads, cutting out of cars (trailers) here and there, backing and hauling about that anything but a universal coupler would be a serious drawback. By standardizing the wheels and bearings it is possible to carry a small stock for making minor repairs without tying up the trailer entirely. Thus a bearing can be removed from any wheel and a new one slipped into place while the old one is being repaired. The same is true about repair to wheels.

As the system is put into actual operating practice it will slowly enlarge until the entire handling is taken care of. At this point the dispatching of the equipment will have reached such proportions that it will be necessary to have a superintendent of transportation, whose duty it will be to keep a general oversight of everything connected with the transfer of materials—the men, trucks, paperwork, pavements, all costs. To him is also relegated the duty of devising or passing upon proposed improvements. Minor changes for the betterment of the system should be constantly presenting themselves.

If records have been kept from the beginning of the study of plant transportation, it will be seen that each step pays for itself and the profits made will carry the initial investment. In order to illustrate what can be done, by showing what has been done, the writer will cite a few instances of successful tractor-trailer installations that have paid for themselves and are still continuing to show a large profit over the old methods.

In the Minneapolis Steel & Machinery Co., Minneapolis, Minn., it was found that with the old method of horse-and-wagon intraplant transportation, the cost of handling materials was $1.50 per ton, and it required forty-seven men plus fourteen teams and wagons to perform the operation—which was none too good. In 1917, the company investigated and started to install a tractor-trailer system of transportation. In 1919, the installation had been completed and it was found that fourteen men, three storage battery tractors, fifty-three small trailers, four 4-ton trailers, and two of 2½-ton capacity, a motor truck popularly known as the "jitney" and power-lift transfer trucks, which handled materials in the shops, could handle all the company's materials. The cost had been reduced to 30 cents per ton, and from 50 to 100 per cent more tonnage was handled by the new equipment. This saving of $1.20 per ton handled make an aggregate saving of $200 per day in handling cost alone. It did not require many days' operation to pay for the installation.

In order to show how these fourteen men were distributed, I will give a brief description of the transportation organization. There is a superintendent of transportation, a chief dispatcher, an assistant chief dispatcher, five division dispatchers, four tractor drivers and two men to operate the "jitney" service.

When we consider that forty-seven men were originally required to do the work of these fourteen, it is amazing, and the result of this saving of man-power effected a release of thirty-three men for other work that could not be performed by machine equipment. It will be noted that eight of the fourteen men are required to direct the system. This means that all the heavy work is taken out of the transportation department.

In addition to handling the materials within the plant, these fourteen men, or rather the eight men that direct the department, also keep all records of cost for handling materials, and furnish a complete record of when

Fig. 2 (above)—Old method of handling raw material at Armour Glue Works in Chicago. How would you like to push one of these trucks for an 8-hour day?

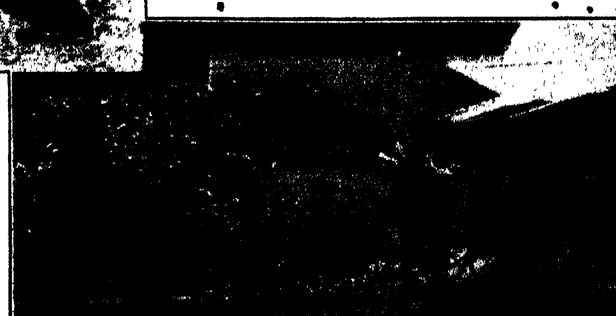

Fig. 3 (below)—Present method of handling raw material at Armour Glue Works in Chicago by tractor-trailer system, handling three times the amount at one-third the expense, with better working conditions for all.

and how the materials were delivered to each department. This information proves very valuable in establishing cost figures.

Tractors in a Chemical Plant

In the plant of a large chemical industry, the use of a tractor-trailer train for handling refuse to the dump pile, for handling salt among the departments, for handling ground sulphur, ice, etc., effected a material saving in time and money, as well as speeding up the production schedule.

There is a tendency on the part of chemical plant executives to feel that their continual change in processes and the use of the same apparatus for making different products make it impossible for them to lay out a route for a tractor-trailer system. This is not correct, because the tractor-trailer system is very flexible. Its line of travel can be changed at a moment's notice, and it is not limited to any one path, as it will negotiate all turns and straight runs that are as wide as the widest part of the train.

This is clearly illustrated in Fig. 1, where the tractor is operated on the dirt floor of a foundry, pulling a train of trailers.

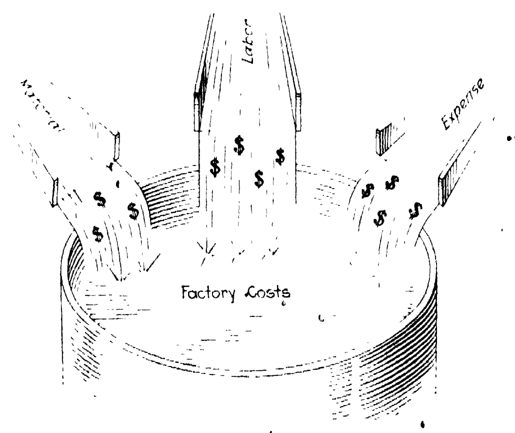
The chemical plant executives also feel that their present hand equipment would have to be scrapped if they were to install the tractor-trailer methods. In the plant of the Armour Glue Works, at Chicago, the raw material used to be handled in hand "buggies" as shown in Fig. 2, and it required two husky men to propel these buggies when loaded. After a tractor had been installed for other purposes it was decided that this operation could be more profitably performed by using a tractor-trailer system. With the slight change in design as shown in Fig. 3, the old equipment became a part of the new tractor-trailer methods, and now one man and a tractor will handle from three to five loaded buggies in one train, with ease.

The method of placing barrels on trailers is shown in the headpiece, and it is often profitable to use wooden runways, provided no heavier trucking than the tractor-trailer trucking is done over them.

Now is the time, during the present labor shortage, to make the greatest use of material-handling equipment, and the tractor-trailer methods should prove of interest to chemical plant executives. They will find that by investigating these methods and installing them in their plants, they will not only overcome the labor shortage but they will also reduce their operating expenses, thereby increasing the profits on their goods.

A Gage of Purchasing Efficiency

An Accounting Method That Enables Executives to Judge the Purchasing Agent and His Judgment of Markets



TWO important factors indicating effective control of manufacturing cost systems are frequently neglected in the design and subsequently in the installation of otherwise excellent systems. The first is the provision for that control which will unquestionably reflect the ability of the purchaser of materials used in the process of manufacture. Is he foreseeing rising and declining markets? And if so, to what extent is the concern benefiting thereby? Considering the large element of material costs entering into the manufacture of most products, it is a continual surprise that more manufacturers do not avail themselves of effective means to control such an important phase of their business.

The features enumerated in the following paragraphs are selected from a system in use by a concern the sales of which run into the millions, and which has branches all over the world and an annual turnover of raw materials of well over twenty. It is easy to see the disastrous results of unwise purchases made repeatedly as is the case when turnovers average more than one per month. The three elements of factory costs—material, labor and factory expense or burden—are thrown together into a factory much as cement, sand and stone are thrown into a concrete mixer.

After a definite length of time, due to effective management, certain products may be expected from the factory in sufficient quantities and of the required quality, ready for distribution to the customer direct or to the branches, as the case may be. These are the facts common to every manufacturer. The recording of the facts in such form as to be of the greatest assistance to the manufacturer varies, however, in nearly every plant. Some are good and some are not. There are certain well-known methods used by the accounting department to collect the three elements of cost and then to differentiate them to the various classifications under each element.* If the voucher register is used, a column may be headed "Factory Ledger," into which all the elements of cost are thrown. This account in the general ledger is the factory control account. It is debited or charged with the total amount of material, labor and factory expense going in to make up the product and is credited with the finished product which is shipped or transferred from the factory. The balance of this account represents the value of the material, labor and factory expense still in the factory either in the form of raw material, work in process or finished goods and therefore is an inventory account.

The factory ledger, a subsidiary ledger, will further classify material, labor and factory expense into additional accounts depending upon the refinement and detail required. It will also contain the following accounts: Factory Inventory, General Stores Adjustment, Manufactured Goods, Cost of Factory Shipments.

Physical inventories should be taken at the factory periodically and should always be priced at cost or market, whichever is lower.

Under the material classification the General Stores account and the Material Used account should be set up as separate accounts, the latter subdivided into the different departments. When the cost of all raw material purchased plus transportation charges have been debited to the General Stores account at the end of the period, the account will have the following appearance:

Debit	Credit
Jan. 31—Purchases ...1000	

The materials used in process of manufacture are collected and classified by products and departments. The totals for the departments are the basis for postings to the debit of the Manufactured Goods account and to the credit of the Materials Used accounts. In pricing materials used, always use *current market prices.*

Every manufacturing department is held up to a back-breaking efficiency because it is easy to calculate the production that should be obtained and compare it with actual accomplishments. Here is a way of doing the same thing with the purchasing department and no one will welcome it more than the efficient purchasing agent.

The balance of each of the Materials Used Accounts are closed at end of period by transfer to the General debited) the General Stores account will be shown thus:

Debit	Credit
Jan. 31—Purchases ...1000	Jan. 31—Used 800

If the amount of inventory on hand at the beginning of the period is now transferred from the Inventory account and the amount of inventory at close of period is credited to this account (Inventory account being debited) the General Stores account will be shown thus:

Debit	Credit
Jan. 31—Purchases ...1000	Jan. 31—Used 800
Jan. 1—Inv. beginning 600	Jan. 31—Inv. close 900

If cost and market price remained the same the above 800, indicating materials used, instead of this amount would be 700, with the result that the account would balance. However, in purchasing materials, a rise in market value was foreseen so that when the materials used were priced, it was found that the market was 800 on what had been purchased at 700, or that a profit of 100 had been made.

It is not the major purpose, of course, for the factory to make profits on material purchases. If such is the purpose, the term "factory" is a misnomer and should be relegated for that of "Jobber." On the other hand, the factory should not incur a loss in its material purchases.

The above credit balance of 100 at the end of the first month's operations should not be used as a basis for immediately formulating any judgment relative to the efficiency of the purchasing department. It will be only after 3 or more months, in which time the balance may alternate from credit to debit, that this account will indicate a positive trend. It is advisable to set up an account to which this balance can be transferred monthly. This account may be called Inventory Adjustment account or General Stores Adjustment account or some similar name. It is, however, a Profit and Loss account and must be treated as such at the end of the year.

The above brings out the first point under discussion. *A credit balance in the General Stores Adjustment account after a certain period will clearly indicate, if inventory and materials used are properly priced, that the purchaser of materials is skillfully making his purchases, while a continued debit balance will just as surely indicate the reverse condition.* With large turnovers it doesn't require much of a loss per turnover to run the accumulated totals into a considerable debit balance. The method of collecting labor and expense and subsequently transferring them to the Manufactured Goods account is only a matter of routine. The balance of the Manufactured Goods account, after inventories have been considered, is transferred to the Cost of Factory Shipments account in the factory ledger, which in turn is transferred as a credit to the Factory Ledger account in the general ledger. When the Factory Ledger account is credited with the actual cost of factory shipments or transfers an account called Manufacturing account in the general ledger is debited therewith.

Impurities in Battery Electrolytes

The importance of obtaining information concerning the action of impurities in storage battery electrolytes arises from the detrimental effects which many of them produce on the operating characteristics and life of the storage battery. Such information is necessary as a basis for the preparation of specifications covering sulphuric acid for use in batteries. A new method of measuring the rate of sulphation of storage battery plates was recently devised at the Bureau of Standards.

It was found that the presence of 1 part in 10,000,000 of platinum in the electrolyte increases the local action at the negative plates 50 per cent; the effect of copper is much less, while the effect of iron is of unusual interest because of its accelerating action at the negative plates. Manganese deposits upon the positive plates in the form of manganese dioxide which covers the active material, closes the pores and causes a large waste of current.

Cooling of Steel Gages

A recent progress report to the gage steel committee, Bureau of Standards, notes that the temperature distribution in a round bar of metal in the quenching bath has been studied.

It has been demonstrated by experiment that in water cooling, the surface is cooled to below 100 deg. C. in 2 seconds, while the center of a 1-in. bar has cooled less than 20 deg. C. In 10 seconds the center has cooled half way, but it is evident that gage specimens cannot be hardened in water and withdrawn before cold for slower cooling through the transformation, without the surface region having already passed that change.

In oil, the center cools half way in 17 seconds with a large temperature gradient which decreases rapidly thereafter, so that the specimen can be withdrawn from the bath when entirely above the hardening change without danger of softening.

The Air Slaking of Lime

The Rate of Deterioration as Well as the Kind of Deterioration of Siliceous, Magnesium and High-Calcium Lime When Exposed to Air Has Been Studied and Is Discussed in This Paper

BY F. H. RHODES,* W. H. JONES AND W. R. DOUGAN

IT IS well known that the essential reactions involved in the slaking of quicklime in air are:

a. The absorption of water vapor by the calcium oxide, with the formation of calcium hydroxide, and

b. The absorption of carbon dioxide by the calcium hydroxide (or oxide) with the formation of calcium carbonate.

Gray[1] and Levi and Orthmann[2] state that the absorption of moisture by quicklime proceeds much more rapidly than does the absorption of carbon dioxide. Whetzel[3] found that high-calcium limes take up moisture more rapidly than do magnesium limes; while the carbonation of magnesium limes takes place more rapidly at first and then more slowly than does the carbonation of the high-calcium limes.

The work described in this present article was undertaken for the purpose of obtaining more exact information as to the relative rates of the reactions which take place when quicklime is exposed to air, and as to the manner and extent to which these reactions are influenced by the impurities normally present in commercial limes.

The samples of lime used in these experiments were obtained through the courtesy of Dr. M. E. Holmes of the National Lime Association. These samples analyzed as shown in Table I.

The calcium oxide, magnesium oxide, silica, alumina, ferric oxide and carbon dioxide were determined by No. C 25-22 T of the American Society for Testing Materials. The water content was calculated as the difference between the percentage of loss on ignition and the percentage of carbon dioxide. The available calcium oxide was determined by the sucrose method.

63	97.22	0.51	0.14	0.56		0.14	1.20	95.11	High-calcium lime

A preliminary experiment was made to determine the rate of slaking of relatively pure lime. About 2 lb. of lime No. 5 (96.97 per cent CaO) was broken to lumps about 2 in. in diameter, while a second sample was ground to pass a 50-mesh sieve. Each portion was spread out in a large porcelain dish and exposed to circulating outdoor air, under sufficient cover to keep off rain and snow. Each lot was stirred frequently to expose fresh surface. At intervals, samples were taken from each lot, care being observed to obtain samples which were as nearly as possible representative of the average mass of the material. In each such sample carbon dioxide, water and active calcium oxide were determined. These results are shown graphically in Figs. 1 and 2. These figures also show the mean temperatures and mean relative humidities of the air, in 5-day periods, for the times during which the samples were exposed.

The results obtained for the rate of change of water content are rather interesting. In each case the moisture content increased rapidly at first until substan-

120	36.0	18.3	14.20	27.1	12.5	21.1

tially all of the calcium oxide was converted into calcium hydroxide, and then decreased slowly as the hydroxide was changed to the carbonate. In both cases the maximum amount of moisture actually taken up by the sample was greater than the calculated amount required to combine with the calcium oxide; and after the conversion to the hydroxide was complete there was present always an approximately constant excess of moisture above that required theoretically to combine with the uncarbonated oxide. Table II shows the changes which took place in the moisture content during the period of exposure.

Apparently the presence of this "excess moisture" is due to the adsorption of water vapor on the surface of the very fine particles of hydrated and carbonated lime.

Absorption of Carbon Dioxide

The rate of absorption of the carbon dioxide was relatively much slower than the rate of absorption of moisture. This would be expected from the fact that the concentration of carbon dioxide in the air is relatively much lower than the concentration of water vapor. It is interesting to note that in each case the rate of absorption of carbon dioxide was greater between the thirtieth and fiftieth day than at any other time. That this was not due to any accidental variation in the concentration of carbon dioxide in the air above the samples is shown by the fact that the increase appeared at the same period in both cases, although the two experiments were not started at the same time, and by the fact that in other samples exposed subsequently similar periods of increased rates of absorption of carbon dioxide were observed at about the same stage in the slaking. Apparently at the end of about the first 30 days the hydrated lime undergoes a slight change in physical structure which results in making the mass more porous and thus facilitating the diffusion of air through the lime; while at the end of about the first 50 days the formation of carbonate films on the hydroxide particles again begins to decrease the rate of carbonation.

The percentage of available calcium oxide in the samples decreases very rapidly at first, during the rapid absorption of water, and then more slowly as carbonation progresses. In every case the amount of active calcium oxide as determined by analysis was less than the theoretical amount as calculated from the percentage of active calcium oxide in the original lime and the amount of water and carbon dioxide which had been absorbed. This discrepancy is slight at first, but increases rapidly as hydration progresses and appears to reach a maximum value several days after the conversion to the hydroxide is complete. The writers are inclined to regard this difference between the observed and the calculated values of the percentages of active calcium oxide as being due to a change in the physical structure of the hydrated lime—probably a conversion of the amorphous and very reactive calcium hydroxide first formed by the hydration into a finely crystalline and less reactive modification.

The values for the contents of available calcium oxide are shown in Table III.

Following these preliminary experiments, portions of limes of various types were ground to pass a 50-mesh sieve and were then exposed to the air for 120 days. Samples taken at frequent intervals were analyzed as described above.

Limes 63 and 44 were relatively pure high-calcium lime. The former was relatively soft and quick-slaking, while the latter was a very hard, dense, slow-slaking lime from oölithic limestone. The changes which took place during the air-slaking of these high-calcium limes are given in Table IV, and are shown graphically by Fig. 3.

In general, the curves showing the change in water content, carbon dioxide content and percentage of available calcium oxide are similar to the corresponding curves obtained in the preliminary experiments.

TABLE V—SLAKING OF MAGNESIUM LIMES

Days Exp.	Lime No. 65 — % Avail. CaO	% H_2O	% CO_2	Lime No. 111 — % Avail. CaO	% H_2O	% CO_2
0	45.17	0.64	0.22	20.19	0.42	0.00
1	44.0	1.20	0.51	30.0	1.10	0.00
3	42.2	2.73	1.71	28.[illegible]	2.21	0.3
5	40.9	3.61	2.02	28.0	3.06	0.42
10	38.1	6.33	2.81	26.2	4.08	1.01
15	35.0	8.92	3.72	24.4	5.42	1.41
20	32.5	11.1	4.50	23.3	6.50	1.71
30	28.9	14.7	5.89	21.0	8.21	2.20
40	26.8	16.8	7.04	19.2	9.50	2.67
50	25.0	18.0	7.72	18.6	11.1	3.06
60	24.2	18.4	8.23	18.4	11.3	3.72
70	23.5	18.6	8.34	18.2	11.7	4.01
80	22.9	18.6	8.51	18.0	11.5	4.37
90	22.2	18.7	8.74	18.0	12.0	4.74
100	21.7	18.8	8.84	17.7	12.3	6.04
110	21.1	19.0	8.86	18.1	12.0	6.22
120	20.6	18.7	9.11	17.5	13.2	5.51

There was a distinct difference between the rates of slaking of the two limes. Sample 63 slaked rapidly, the hydration being complete at the end of about the fifteenth day and carbonation being about 42 per cent complete at the end of the one hundred and twentieth day. Sample 44—the dense, hard lime from oölitic stone—slaked much more slowly, hydration being complete only after about 50 days' exposure and carbonation being only about 29 per cent complete at the end of the one hundred and twentieth day.

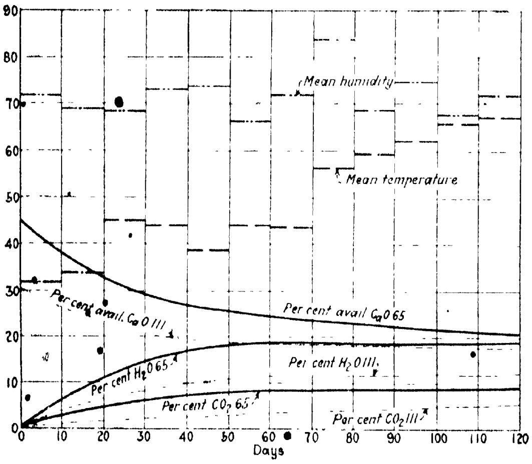

FIG. 4—AIR SLAKING OF MAGNESIUM LIMES

The changes which took place during the slaking of the magnesium limes - samples 65 and 111—are presented in Table V and are shown graphically in Fig. 4.

The hydration of the magnesium limes took place much more slowly than did the hydration of the high-calcium limes. Moreover, the water content did not, within the time covered by the experiments, attain a maximum value. In each of the magnesium limes the amount of moisture increased rather slowly at first and then remained almost constant. Apparently the calcium oxide reacted with the atmospheric moisture to form hydroxide, and the water liberated by the carbonation of this hydroxide reacted with and was retained by the magnesium oxide.

During the earlier stages of the slaking the magnesium limes carbonated more rapidly than did the high-calcium limes. The rate of carbonation decreased, however, during the latter part of the period of observation, so that the amount of carbonation was ultimately less than that obtained with the purer limes.

The available calcium oxide content decreased regularly as slaking progressed. The rate of decrease of active calcium oxide was much slower than that observed with the high-calcium limes. The writers assume that the slower decrease in available calcium oxide was caused by the fact that the magnesia inhibits the conversion of the very reactive amorphous calcium hydroxide into the less reactive crystalline modification.

The observed differences between the rates of slaking of the two magnesium limes correspond to an observed difference in the physical properties of the limes. Sample 65 was rather soft and light, and apparently had been burned at a relatively low temperature. Lime 111 was dense and hard and appeared to be slightly overburned.

The results obtained in the slaking of two typical siliceous limes are shown by Table VI and Fig. 5.

It will be observed that these two samples behaved very differently. Lime 53 acted very much like a typical high-calcium lime. The water content increased rapidly to a maximum value of 20.8 per cent and then again decreased. The percentage of carbon dioxide increased very slowly during the first 100 days, and then began to increase rather rapidly. The percentage of calcium oxide decreased rapidly at first, and then more slowly;

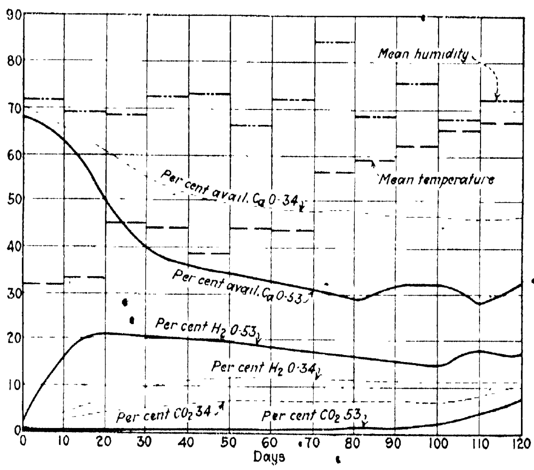

FIG. 5—AIR SLAKING OF SILICEOUS LIMES

and the decrease in the content of active calcium oxide was much greater than would be expected from the amount of carbon dioxide and water which were absorbed.

On the other hand, Lime 34 behaved much like the magnesium limes. The water content increased rather slowly to about 12 per cent and then remained almost constant throughout the remainder of the period of observation. The percentage of carbon dioxide in-

100	46.5	11.2	6.98	32.3	14.7	2.31
110	46.0	11.3	8.21	28.0	17.6	4.46
120	46.4	11.2	10.16	32.6	16.7	7.28

creased slowly at first, remained almost constant for about 50 days, and then began to increase again. The percentage of available calcium oxide decreased rapidly during the first 50 days, and more slowly thereafter, but the decrease was much less than the decrease observed with lime 53.

A comparison of the analyses of the two original limes shows no evident reason for this difference in slaking. Lime 34 contained considerably more magnesia than did lime 53, but the amount of magnesia was hardly sufficient to explain the anomalous behavior.

SUMMARY

In the slaking of lime in air, the essential reactions are (1) the absorption of moisture with the formation of calcium hydroxide, and (2) the absorption of carbon dioxide with the formation of calcium carbonate.

With relatively pure high-calcium limes, hydration takes place much more rapidly than does carbonation. The amount of water actually taken up by the lime is greater than that theoretically required to convert the oxide into hydroxide. This excess water is probably moisture adsorbed on the surface of the particles of hydroxide and carbonate. The percentage of "active calcium oxide" in the material decreases very rapidly as hydration and carbonation proceed, the decrease in active calcium oxide being much greater than would be expected from the amount of water and carbon dioxide absorbed during slaking. This abnormal rate of decrease of "active calcium oxide" is probably due to the crystallization of the very reactive amorphous hydrate and the formation of relatively inert crystalline hydrate. It should be noted, however, that the slaking is accompanied by an increase in weight, so that the decrease in the *weight* of available calcium in the partially slaked lime from a given original portion of quicklime is considerably less than the decrease in the *percentage* of available calcium oxide.

With magnesium limes there is a more regular and more gradual increase in the percentages of water and carbon dioxide, and a more uniform and less rapid decrease in "active calcium oxide." Some siliceous limes behave very much like pure high-calcium limes; others act very much like magnesium lines.

The data obtained for the rate of hydration and carbonation in these experiments cannot be applied directly to the slaking of lime under all conditions, for in any case the rate of slaking will depend on the size of the heap, the method of piling, the amount of moisture in the air, and other external and independent factors. These results do serve, however, to throw some light on the general progress of the slaking reactions with different types of limes.

Gases in Metals

Tests conducted at the Bureau of Standards on the completeness of recovery of oxygen from oxides of iron and silicon in the vacuum fusion method for gases and metals have indicated complete reduction and recovery in both cases. Other oxides which may be present in steels are now being tested. Through the co-operation of a manufacturer of malleable cast iron, some tests have recently been made which indicate that results for oxygen by the Ledebur method on white cast iron are of little value because of the surface oxidation of the sample during its reduction to a finely divided form.

Annual Meeting of Manufacturing Chemists Assn.

Report of Executive Committee Presents Significant Sidelights on Important Problems Affecting the Industry

THE EXPANDING ACTIVITY of the Manufacturing Chemists Association for the year ended May 31, 1923, follows the curve of increasing industrial production very closely. With gathering momentum in business activity many calls arose for change and readjustment of standard practices, and increased use of the association facilities was made by member companies.

The policy of the association in regard to the tariff has always been to prepare in advance for a change and to aid the committees of the government to the limit in giving information with regard to the chemical industry. The association commends President Harding's attitude with regard to changes in accordance with the flexible provisions of the tariff. The President has announced his unwillingness to make any changes unless the facts show conclusively that they are absolutely necessary. Higher rates than are essential to protect against lower labor and production costs abroad are not advocated by the association.

FAVOR WORKING CLAUSE IN PATENT LAW

At the invitation of Senator Stanley, who introduced the patent bill, Henry Howard, as chairman of the executive committee, prepared a form incorporating a working requirement. This form embraced the modifications required to meet the objections raised by the American Patent Attorneys' Association and certain industrialists. Senator Stanley adopted this draft, and this was among the many measures pending when Congress adjourned on March 4 last. Lack of success in the last Congress to obtain this legislation does not mean that the effort has been abandoned. The introduction of the same or of a similar bill in the next session is expected.

INDUSTRIAL WASTE LEGISLATION COMING

Although the original bills introduced into Congress with regard to industrial waste were aimed at prevention of pollution of the waters of the Atlantic seaboard, later these were enlarged to cover the country generally. Fearing that a blanket law applied without careful investigation would work undue hardships upon chemical manufacturers, the association opposed its passage.

Many other important matters have received attention from the executive committee. It has supported the bill to define and prohibit commercial bribery. It has opposed drastic prohibition enforcement bills which would have crippled chemical industries. It has supported the chemical division of the Bureau of Foreign and Domestic Commerce.

In addition a number of special committees have carried out important investigations. The work of the carboy committee has already been referred to in *Chem. & Met.* Other committees have worked on the multiple unit tank cars, the standardization of laboratory apparatus, the best practice in handling and unloading acid tank cars, the formulation of standards for steel drums and the shipment of acid less than 65 deg. Bé. in steel drums.

Unemployment and the Sales Machine

How the Spring Meeting of the Taylor Society at Syracuse Considered This Subject in Its Various Aspects

EDITORIAL STAFF REPORT

TAKING as a subject the report of Secretary Hoover's committee on business cycles and unemployment, this meeting of the Taylor Society was held on June 7, 8 and 9, for the purpose of studying the effect of unemployment on industry and to bring out the factors that would tend to stabilize employment. With this information in hand, a study was made of other departments of industry, such as the sales department and the planning division, noting what these could do in eliminating the causes that have resulted in unemployment in the past.

Dr. Willford I. King, of the Bureau of Economic Research, New York City, was instrumental in furthering the work of this Hoover committee. It was Dr. King's bureau which provided the statistical background upon which its findings were based. Dr. King spoke on the general subject of "Safeguarding Industry by Stabilizing Employment." In this talk the factors leading to unemployment were pointed out, by means of a study of the business cycles and various industrial statistics.

One of the first facts noted in this statistical research was that the lay-off of labor at the last depression occurred primarily in construction, factory and mines. There was no commensurate falling off of employment in retail business. The next factor studied was the interrelation between farm labor and industrial labor, and it was found that there was no appreciable shift, back and forth, between the farm and the factory. Another factor brought out was that the lay-offs occurred chiefly in large plants, and that the plants employing up to 100 workers showed no appreciable diminution in employment.

WHAT CAUSES THE BUSINESS CYCLE

This leads one to the possibility of there being some connection between large units in industry and the business cycle. From a careful study of the factors, Dr. King pointed out that this is probably not the case, but that the business cycle is caused by the action of retail business. Because the small manufacturer more generally meets his final customer direct and does not trade through the large retailers, his business is not affected, while the business of the large manufacturer, who deals through retail stores largely, is immediately affected by the behavior of the retailer.

The real cause then of the business cycle, as determined by this study, is the failure of the retailer to sell the consumer a sufficient amount of merchandise. The first result of this is lower orders from the retailer to the manufacturer. These lower orders to the manufacturer immediately result in unemployment in the manufacturer's plant, while the retailer's store, having its shelves full, must keep its employees in an endeavor to empty the shelves. By the time the business has caught up with itself again, the demand is good and the retailer needs all his employees for business purposes, while the manufacturer again builds up his employment.

Dr. King suggested several ways in which this trouble could be eliminated. His remedies were to scrutinize carefully all orders received, keep a fair reserve of cash, in boom times be very slow to raise wages and increase the working force, at all times keep a trained force in the plant, and finally keep a careful watch on the stock of unworked materials that they do not represent too much frozen capital.

From this paper of Dr. King and his remarks on the subject of the failure to sell goods to the consumer, we are led directly to the paper read by Prof. H. R. Wellman, of Dartmouth University, on the subject of the sales machine. Dr. Wellman opened his paper with several precautions to manufacturers, pointing out the possibility of sales saturation existing at any given moment, although it could not exist in the long run; and suggesting the possibility that business might be urged beyond the point of profit. He further pointed out that, at the present time, the average cost of marketing commodities is 68 per cent of the cost of production. These figures seem to him to be out of all reason, and the time is ripe for a reduction of these costs.

SOME REMEDIES SUGGESTED

Coming down to the main remedy for the failure of the sales departments and retail organizations to sell the goods produced by manufacturers, Dr. Wellman pointed out the absolute necessity of a well-thought-out and rationally based sales plan. In Dr. Wellman's words, "the sales plan must be based on the facts and not on theory; on the present and not on the past."

In forming a sales plan the essential elements are simple, although in following them out one may be led into a quite detailed study. These elements are: (*a*) study what has been done by means of the company's records; (*b*) study what can be done from market analysis; (*c*) determine what, from the two elements (*a*) and (*b*), shall be done. It is in this last that the essential factor of executive ability enters, in that judgment must be used.

Having made the analysis suggested above and determined the line of operation for the sales department, it is then possible to establish definite sales quotas, to determine the proper compensation for sales effort and to budget the total business along with the production department budget.

It is from the necessity of making this budget in order to control sales and thus stabilize the business that one is led directly to a study of the planning department of a business. In this connection, Keppele Hall, of the Joseph & Feiss Co., of Cleveland, gave before the society a description of what an ideal planning department was. It was pointed out by Colonel Hall that the planning department was, in reality, a service department for the whole business. It is its duty to study all phases of a business—finance, production, purchasing and sales. From the results of this study the mangement must be provided with proper figures and information upon which can be based the scientific, systematic and rational conduct of industry.

Having been led from a study of the question of unemployment to the heart of scientifically managed business—the planning department—the rest of the time of the convention was taken up by the study of some good examples.

An extremely interesting trip was taken to the plant

of the Corona Typewriter Co. at Groton, N. Y. This plant has been well known for many years for the perfection of its management system. The feature of its system lies in the fact that a careful study is made of the sales possibilities, and the manufacturing necessity is determined from this study. The planning department then organizes for a long period ahead, on the basis of this study, and employment conditions are in this way maintained at a stable point.

Following this inspection a visit was made to the plant of the H. H. Franklin Manufacturing Co., maker of the well-known Franklin automobile. This plant was one of the first to establish the Taylor system. By means of careful and efficient planning, it has information on hand many months in advance of the number of cars which it desires to make to meet its sales demands. In this way the company is able to order its stock at least 6 months in advance, and to work on this stock far in advance. The result is the flattening out of variations in the employment curve and a general stabilization of the industry, which results in efficient management and good employment conditions.

British Chemical Industries

Nitrogen Fixation Again to the Fore—Developments in Blast-Furnace Construction and Alcohol Production

FROM OUR LONDON CORRESPONDENT

LONDON, May 19, 1923.

THERE is nothing of importance to report in regard to chemical markets during the past month, the position having remained stable and prices firm with low stocks. The continental situation is still a dominating factor, and its effect has been substantially that anticipated by the trade. It is felt that even if a solution to the present impasse should be found, there can be no revival of serious competition from Germany for a considerable time to come. The political situation is a little obscure, several sections of the press are predicting the resignation of Bonar Law, and people are gloomy or optimistic according to their own fancy in regard to his possible successor as Prime Minister.

INTEREST REVIVED IN NITROGEN FIXATION

During the war about twenty secret patents were filed by the government, based on investigations carried out at the research laboratory established during the war under the auspices of the Nitrogen Products Committee, and in many cases corresponding patents were taken out in foreign countries and British possessions covering ammonia synthesis, manufacture and purification of industrial gases, oxidation of ammonia and the manufacture of nitrates. Subject to the right of Brunner Mond & Co. to non-exclusive licenses, the Disposal Board has invited offers for these patents, but as tenders must be received not later than May 25, it seems doubtful if any serious or definite proposals can materialize from interests other than British. One of the most interesting of these patents was that of an explosion compressor evolved by H. A. Humphrey somewhat on the lines of his well-known pump. Humphrey had in mind the combination of the Häusser explosion process with an air compressor operating as one unit with a free piston, and it was calculated that for an output of 2 tons of nitric acid per day about 3,000 kw. could be generated continuously, part of which would, of course, be required for working the process. The wisdom of combining a power unit with the nitric acid explosion unit is open to the great objection that when acting efficiently as a compressor, the nitric acid yield is probably low and, conversely, an apparatus designed primarily for nitrogen fixation is likely to prove an inferior compressor. Additional interest in the Häusser process for combining oxygen and nitrogen when coke-oven gas is exploded has been aroused by two recent papers of Prof. W. A. Bone, read before the Royal Society and the Royal Institution. Professor Bone claims that the elimination of hydrogen as a component of the flammable mixture so as to leave substantially carbon monoxide as the sole combustible constituent gives rise to conditions under which the nitrogen assumes abnormal activity with increased yields of nitric oxides. As a matter of fact, a process covering the removal of hydrogen from coke-oven gas for this purpose is already being developed, so the way to practical results is, to some extent, prepared. It is open to question whether Professor Bone is right in using the word "activation" in describing this phenomenon, which is apparently feasible only when there is less than about 2 per cent of hydrogen present, but to the industrial world the chief interest lies in a complete thermodynamic solution and practical results.

PROGRESS IN BLAST-FURNACE FUEL ECONOMY

Sutcliffe & Evans have again done something revolutionary on the basis of their previous researches and if their claims are substantiated, the quantity of fuel per ton of pig iron may be reduced to something like 12 cwt. The investigations have shown that the chief factor in the blast-furnace process is the "combustibility," or, let us say, the chemical reactivity with oxygen of the coke used, which depends largely on its physical condition and especially on its porosity. The desirable properties of a good blast-furnace coke are well known, and Sutcliffe & Evans claim to have produced a smokeless fuel made by carbonizing briquets composed of 80 per cent coal and 20 per cent coke breeze, which is harder than metallurgical coke, is in fine granular condition and has a porosity practically equal to charcoal. It is understood that the process is to be tested on a commercial scale soon.

PROCESS FOR UTILIZATION OF WASTE CELLULOSE

Messrs. Lynn and Langwell have given an account of their process for transforming cellulose directly into alcohol, fatty acids, etc., by means of bacteria and without the use of considerable quantities of relatively expensive chemicals. The basic British patents are Nos. 134,265 and 161,294 and the basic discovery is that of a bacillus which rapidly attacks almost every form of cellulose under either anaërobic or aërobic conditions. This organism thrives and does its work at the extraordinary temperature of 68 deg. C., at which any ordinary form of vegetable fiber (excepting wood or cork) is decomposed, forming carbon dioxide and, in addition, alcohol, acetic acid, butyric acid, methane and hydrogen or varying mixtures of these according to the conditions. The process is being worked on a large scale at the works of Power Spirit, Ltd., Epsom, and in view of the large amount of inedible waste vegetable fiber annually produced, it seems possible that this process may be of considerable economical and technical importance.

Production of Hydrogen by the Thermal Decomposition of Oil

The Concluding Article of a Series Describing Government Experiments in Producing Pure Gas for Air Service Requirements—Arrangement and Operation of Plant for Thermal Efficiency—Cost Considerations

BY E. R. WEAVER
Chemist, Bureau of Standards

THERE are two reasons for the excessive heat losses in blast gas and by radiation: (1) The great difficulty, in a two-shell plant, of burning the finely divided carbon deposited in the vaporizer to CO_2 or of utilizing any considerable portion of the heat produced from it; and (2) the long blasting period required to get the plant up to a sufficiently high temperature at the beginning of the run. Most of the difficulty occurs in the last 100 or 200 degrees; if the blasting period can be shortened, by the use of preheated air or otherwise, considerable economy must result.

BURNING CARBON DEPOSIT

The carbon deposited in the vaporizer is so finely divided that it is particularly difficult to get anything but carbon monoxide while burning off the checker brick. If air is introduced only at the bottom of the checkerwork, all the carbon will be burned off at the bottom and the bricks subjected to the cooling action of the air stream before the top of the column is cleared. At the same time the upper part of the tower is subjected only to the temperature of carbon monoxide production, and a large part of the fuel escapes as unburned carbon monoxide. If any considerable benefit is to be derived from the deposited carbon, it will be necessary so to arrange the air inlets that the carbon is burned off in all parts of the tower at about the same time. Practically it is impossible to do more than introduce air at four or five levels in approximately the right proportion. After the carbon is removed from the checker brick the blast gas from the generator can be burned completely in the tower and its fuel value utilized to the utmost; while carbon is present, blast gas from the generator is entirely wasted. For this reason, and because it is desirable to blast the generator strongly just before a run in order to have a maximum temperature in the coke bed, much better results are obtained by burning the carbon from the brick before starting to blast the generator than by blasting the two simultaneously.

It was found in practice that more time is required to burn the carbon from the checker brick than to make a run. It should therefore be possible to save much time and a considerable amount of radiation from the generator by employing two vaporizers with one generator, the carbon being burned from one while a run is being made with the other.

The use of regenerators for preheating the air used in the generator should also effect a considerable eco omy. Just how much fuel can be saved by means these improvements is uncertain. It may be qui possible to reduce the consumption of coke in the ge erator to the small amount of compact solid unavoidab burned while burning out the deposited carbon to pr vent the clogging of the gas passages.

Figs. 18 and 18A show semi-diagrammatically th arrangement believed to be most economical for a pla of large capacity. Each vaporizer is here divided be tween two shells called the vaporizer and superheate This permits the oil to be introduced at the top an coolest part of the checkerwork; it places the hottes part of the checkerwork and linings under minimu load; and on account of the shorter connections, th two shells should cost but little more to construct tha a single shell of equivalent capacity connected to permi the blast to enter the bottom.

REFRACTORIES REQUIRED

Probably the most difficult problem encountered i connection with the process is that of obtaining suitabl refractories for linings and checkerwork. Followin the plant experiments, load tests were made at hig temperature in the ceramic laboratories of the Burea of Standards for the purpose of ascertaining the mos suitable materials for the purpose. Including the hal dozen materials which had already been eliminated b use in the plant, every refractory known to be com mercially available and which it was believed migh meet the requirements of the plant was tested. O these materials, two were found to have propertie

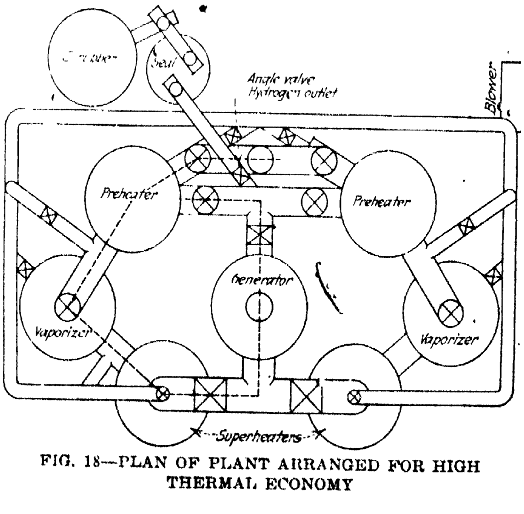

FIG. 18—PLAN OF PLANT ARRANGED FOR HIGH THERMAL ECONOMY

Published by permission of the Director of the Bureau of Standards of the United States Department of Commerce.

which should make them of the greatest value. They were self-bonded silicon carbide and a kaolin product made by a recently developed process, the details of which have not been made public. Both refractories were tested under a load equal to the weight of a 15-ft. column of the same material.

The kaolin brick showed only a small contraction under the load at a temperature as high as 1,600 deg. C. and did not fail decisively until 1,675 deg. C. was reached. The silicon carbide brick showed no signs of injury at a temperature of 1,725 deg. C., which was the highest obtainable in the furnace used.

A comparison with some of the refractories used in the plant indicated that had kaolin brick been used there would have been but little if any injury at the temperature obtained during the experimental runs, and that a temperature at least 200 deg. C. in excess of those employed would not have seriously affected silicon carbide linings and checkerwork. The silicon carbide was also free from reducible iron compounds. The kaolin was not, but it is believed that a similar material practically free from iron can be obtained at a price considerably below that of silicon carbide. No serious difficulty should be encountered with refractories in a plant having an inner lining and checkerwork of silicon carbide. For purposes of economy the kaolin refractories should be used in the cooler parts of the plant. If a preheater for air is employed, there is no necessity for using in it any refractory of a quality superior to that of the average firebrick.

If a single vaporizer is used with the generator and preheating the air is not resorted to, there is no need for any valve subjected to high temperature except the stack valve. If, however, two vaporizers and preheaters are used with a single generator, a number of hot valves are required. Experience with the experimental plant indicated that a great deal of difficulty would be encountered in keeping a steel or iron valve in condition under such severe service even if water-cooled, and that the heat lost in such a valve during the producing period is far from a negligible factor in determining the capacity of the plant.

It has been found that machined surfaces of the nickel-chromium alloy Nichrome will remain in good condition at a temperature at least 500 deg. C. hotter than will machined steel surfaces. The valve heads and seats should therefore be made of this alloy. For economical reasons, however, the Nichrome parts should be as small as possible. The valves between vaporizer and generator and vaporizer and preheater may reach a temperature higher than the softening point of Nichrome, hence the castings made of it should be in contact with water-cooled steel supports in order that the exposed parts may be cooled below the danger point by conduction. The Nichrome parts of other hot valves in the plant will be in no danger of injury from the heat, but the valve stems must be water-cooled to prevent carbonization of the packing. The valves between the vaporizers and the generator should be of the double-gate type with a vent between the gates in order to indicate at once any failure of the gates to seat tightly and to prevent contamination of the hydrogen in case such a failure occurs. The valve mechanism indicated in the drawings of the proposed plant is merely suggestive. Several of the ordinary types of valve mechanism could be employed successfully in hot valves of the character described. Fig. 19 shows details of some of the valves and refractories proposed.

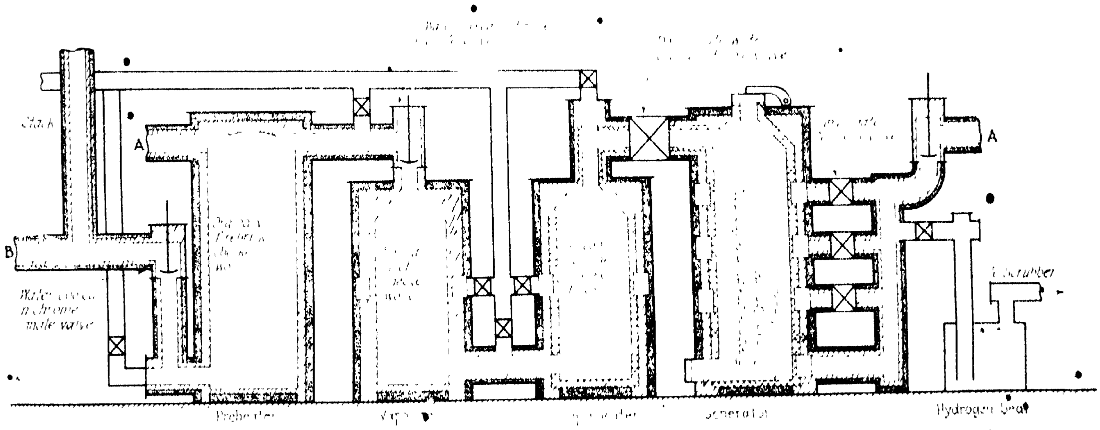

FIG. 18A. DIAGRAMMATIC SECTIONAL ELEVATION DEVELOPED ALONG LINE DOTTED ON PLAN

It is certainly desirable if not absolutely essential to use in the generator a solid fuel practically free from ash-forming constituents. The fuel may be either pure carbon or carbon containing a considerable quantity of heavy hydrocarbons, in which case some hydrogen will be recovered from the solid fuel.

Coke—If an ordinary coke is used, it is impossible to obtain a sufficiently high temperature without completely fusing the ash and producing a clinker very difficult to handle. This difficulty would be serious enough if air were blown in only at the bottom, but when secondary air is used in large quantity and clinker is produced throughout the fuel bed, the operation of the plant is almost impossible. The fused clinker also attacks the generator linings, which present a sufficiently serious problem without this complication. Even if the clinker could be handled in the ordinary way, at least two men would have to be employed to remove the clinker at frequent intervals, interrupting the operation of the plant and permitting it to cool off. The amount of solid fuel used is not large, and the amount of labor, interruption to service and deterioration of refractories involved in the use of an ordinary coke are out of all proportion to the saving in the cost of the fuel at the present time.

Retort Carbon—Retort carbon is an ideal fuel for use in the process, both because it is free from ash- and clinker-forming constituents and because its high density and heat capacity permit long runs.

The only serious objection to the use of retort carbon

is the limited supply available. It is an unimportant byproduct of a coking process which is being supplanted by other methods, and no increase in the demand for the material is likely greatly to increase the supply. The present production in this country is only about 1,000 tons annually and probably half that amount is used by the carbon companies in the manufacture of their varied products.

Petroleum Coke—Petroleum coke is commercially available in sufficient quantity and burns practically without residue; but as ordinarily produced, the material is so porous and has such low heat capacity that only comparatively short runs are possible. The porosity of the material is no doubt of advantage in presenting a larger surface to the oil vapors; it is probably a disadvantage in blasting, because it shortens the zone of carbon dioxide formation in which alone the temperature necessary for complete decomposition of the hydrocarbon can be attained.

The most satisfactory solution of the fuel problem would appear to be the manufacture of petroleum coke briquets of high density. Similar briquets have been made cheaply and in large quantity from the lampblack produced by the oil-gas process on the Pacific Coast. These have been used successfully in water-gas manufacture in which the requirements are substantially the same as in the present process. Petroleum coke appears to be a more suitable raw material than lampblack; coal-tar pitch is probably the most suitable binder.

If this process were to be employed on a sufficiently large scale, it would certainly be most advantageous to purchase the residue from petroleum refining at such a stage that it would produce oil and carbon in proper proportion and to complete the distillation at the hydrogen plant under conditions which would yield a dense residue. In this case the abundant waste heat of the hydrogen plant would be employed for the distillation and the hydrocarbon vapors conducted to the hydrogen generator without condensation. The cost of hydrogen produced on a large scale by this process should rival that of the cheapest methods for producing hydrogen from water-gas so extensively employed in Europe for the synthesis of ammonia. It is probable that a hydrogen plant operated as an integral part of an oil refinery utilizing hydrocarbon gases and residues of every kind which could not be otherwise disposed of to greater advantage, supplying waste heat for the operation of the oil stills and consuming a part or all of the coke produced by the refinery, would yield hydrogen at lower net cost than any other known process.

The first cost of a plant combining distillation with hydrogen production, and the skilled operation it would require, make it unsuitable for intermittent operation and therefore out of the question for an aviation field. It is therefore beyond the scope of this investigation, and the possibilities of such future developments are merely suggested.

Probable Cost of Hydrogen

The following cost estimates are intended to serve as a guide in determining the probable cost of producing hydrogen under a variety of conditions. The quantities of fuel required and the capacities of the various plants are conservatively estimated from the results of the experiments with a 4.5-ft. generator and a single vaporizer, assuming that the amount of gas produced per run will be proportional to grate area.

The unit costs of materials, investment, labor and repairs vary so much under different circumstances that the reader should regard the figures given as merely illustrative of the manner in which these factors affect the cost of the product. The estimates are made for hydrogen containing not more than 1 per cent of methane; the exclusion of carbon monoxide depends

FIG. 19—DETAILS OF REFRACTORIES AND VALVES

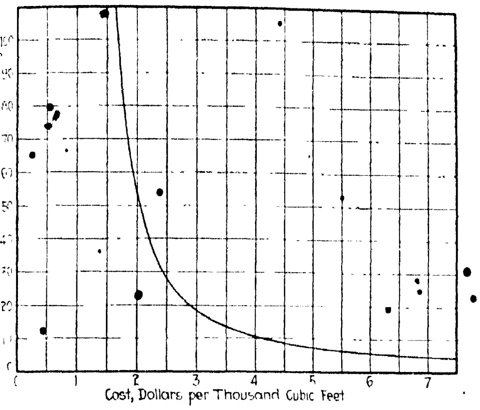

FIG. 20—APPROXIMATE RELATION BETWEEN DAILY PRODUCTION AND COST OF HYDROGEN

entirely upon the extent to which it is possible to eliminate iron oxide from the plant.

The experimental plant made about 13,000 cu.ft. per run under favorable working conditions with a coke consumption of not over 30 lb. per 1,000 cu.ft. Three runs are easily made per 10-hour day. Fuel oil actually cost 8.25c. per gallon delivered in Trenton, and retort carbon cost $15 per ton at point of origin, to which $8 freight and hauling charges had to be added. One man should be able to operate a well-equipped plant under normal conditions provided other workmen are at hand to assist him in case of emergency. The air blower consumes practically all the power used. Twenty horsepower is sufficient for this purpose for a 4.5-ft. generator and is assumed proportional to grate area for larger installations. The cost of repairs will depend principally upon the frequency of replacement and cost of refractories. Other repairs should not be expensive.

Cost estimates are tabulated in Table III for the conditions stated in the following several paragraphs. The column of the table headed by a certain letter contains the figures corresponding to the conditions stated in the paragraph marked with the same letter. The estimated cost of the plant does not include housing or hydrogen storage.

A. Plant—A 4.5-ft. generator with a single vaporizer. Estimated cost of plant, $35,000. Average production, 10,000 cu.ft. per run; one run per day on 300 days per year.

B. Plant—Same as in paragraph *A*. Average production, 10,000 cu.ft. per run. Three runs per day on 300 days per year.

C. Plant—A 6-ft. generator with a single vaporizer. Estimated cost of plant, $45,000. Average production, 25,000 cu.ft. per run; three runs per day on 300 days per year.

D. Plant—Same as in paragraph *C*. Average production, 25,000 cu.ft. per run; nine runs per 24-hour day on 360 days per year.

E. Plant—A 6-ft. generator with two vaporizers and two preheaters. Estimated cost, $70,000. Average production, 25,000 cu.ft. per run; five runs per day on 300 days per year.

F. Plant—Same as in paragraph *E* with an additional briquetting plant for making a dense fuel from petroleum coke. Estimated cost of plant, $85,000. Average production, 25,000 cu.ft. per run; fifteen runs per 24-hour day on 360 days per year.

G. Plant—Two 8-ft. generators, preheaters and superheaters equipped for distilling petroleum residues to supply both hydrocarbons and contact carbon. Estimated cost of plant, $150,000. Average production, 55,000 cu.ft. per run; thirty runs per 24-hour day on 360 days per year.

TABLE III—ESTIMATED COST OF HYDROGEN

	Plant *A*	Plant *B*	Plant *C*	Plant *D*	Plant *E*	Plant *F*	Plant *G*
Average daily production. Thousands of cu.ft.	8 2	25	62	225	100	375	1,650
Costs, Cents per 1,000 cu.ft							
Fuel oil at 8 cents per gal.	43	43	43	43	43	43	..
Dense carbon fuel at $35 per ton	88	61	61	52	52	.	
Petroleum coke at $20 per ton				.		25	
Petroleum residues, 30 per cent free carbon at $8 per ton						..	17
Labor and superintendence	80	44	18	9	11	8	3
Electric power at 2 cents per kw.-hr	20	13	13	10	12	10	8
Repairs and miscellaneous operating expenses	30	25	20	15	20	15	10
Eight per cent of investment for interest, taxes, etc	94	31	16	5	15	4	2
Amortization (full value in 10 years)	117	39	20	6	19	5	3
Total	$4 62	$2 56	$1 91	$1 40	$1.72	$1 10	$0.43

The estimated costs given in Table III are plotted against the assumed daily production in Fig. 20.

The experimental work described in this paper was carried out by S. F. Pickering, P. G. Ledig, C. P. Larrabee, A. H. Graham and F. W. Trapp, under the direction of the author, who wishes to acknowledge the loyal co-operation of the whole group. It is a pleasure also to acknowledge the interest taken in the investigation and the assistance rendered by F. E. Crowell, engineer of the Gas Engineering Co.

Crystallization or Poor Heat-Treatment?

British engineering papers during the early part of May gave much attention to the report of an accident which occurred last December on the London & Northwestern R.R. While traveling at about 60 miles an hour, a locomotive driving axle broke short off, just inside the wheel hub. An investigator for the Ministry of Transport reported that the various tests on the broken part showed that it was made from a badly segregated heat of steel. He also said that the fractured surface had the appearance common to a failure due to "fatigue."

On the other hand, a report from the National Physical Laboratory, which was consulted on the case, said specifically that the test pieces were coarsely crystalline, and the break was a type of fracture typical of *overheated* steel.

In England as well as in America there is a lack of understanding between modern metallurgical investigators and the older school of mechanical engineers engaged by railroads and other large consumers. As a matter of fact, it seems increasingly clear that a vast majority of the breaks that are commonly called "crystallization breaks" or "fatigue fractures" are due to improper refinement of the grain by heat-treatment after the forging operations.

The failure in question is one extremely difficult to have been detected at any time subsequent to the steel-making process. Segregation and piping occurred toward the axis of the piece, and the outside material, which was sampled, showed correct chemical analysis and good physical properties.

It is to be emphasized, of course, that eternal vigilance is the price of safety. The total stress on the part which failed was not much more than 6,000 lb. per sq.in. over the whole area, which allows a factor of safety of nearly 12 for the particular steel used. This margin would certainly appear to be adequate for all purposes, and it is suggested by *The Engineer*, in its issue of May 4, 1923, that there was either an original flaw existing near the surface of the axle or that it was scratched during machining or at some other time before the wheel was pressed on. Such surface scratches are known to be very damaging.

Legal Notes

Of the Chicago Bar

Fixing Profits of Infringing Machine

Plaintiff Loses Claim for Damages Through Failure to Establish Proper Standard of Comparison

What is the proper measure of damages for infringement is involved in the suit of the DeLaski & Thropp Circular Woven Wire Co. against the Empire Rubber & Tire Co., involving the DeLaski & Tropp patent, No. 1,011,450, for a machine for wrapping automobile tires before vulcanization. In another case the U. S. Court of Appeals held the patent valid and the U. S. District Court in this case held the patent valid and infringed and awarded the plaintiff damages, but declined to award it profits and to treble the damages. Both parties appealed from this judgment, 287 Federal 1

The question of profits turned on the question of what constitutes a proper standard by which to compare the gains and savings made by the use of the infringing machines over other means available at the time for doing the same work.

Another machine, known as the Williams machine, was also used by the defendant for the same purpose as the infringing device. These machines the court regarded as the proper standard of comparison The plaintiff, however, insisted that original hand wrapping as done before the invention was the proper standard But since the Williams machine and other machines, though not of the utility of the machine infringed, were not only available but used by the defendant, they became the proper standard of comparison

As the plaintiff built its case upon hand wrapping as a proper standard of comparison, which was rejected by the court below, the Court of Appeals said there had not been any evidence given as to gains and savings in the use of the infringing device measured by the proper standard as adopted by the lower court, and therefore there was nothing in the record to support the plaintiff's claims for profits, therefore its claims must fail.

Sales Agreement Proves Unenforceable

No Valid Contract When One Party Reserves the Right to Cancel at His Pleasure

The Federal District Court has said that an agreement by defendant to purchase a stated quantity of a product per week so long as it was made by plaintiff and conformed to sample, and for plaintiff to deliver such quantity "every week thereafter," does not constitute a contract binding on the defendant, since the plaintiff might cease manufacture at will, without violation of the agreement. This is laid down in an action on a contract brought by Edward J. McCaffrey against B. B. & R. Knight, Inc., 282 Federal 334.

The seller did not agree to manufacture goods of the kind or quality for any particular period, and if he should cease to manufacture goods of that kind, or goods which conform to the sample, he would not be liable for a breach of any obligation which he had assumed or which was imposed upon him by the contract, says the court.

The seller rested his case on a decision in McMullan vs. Dickinson Co., 63 Minn. 405. Here the defendant had agreed to keep the plaintiff in its employ so long as he retained the ownership of a substantial number of shares in the corporation and it continued in business. In this case the court said: "The expressions of a contingency whereby the contract might be terminated by the act of either party expressly excluded the idea that each was at liberty to terminate it at any time without regard to the happening of either contingency."

In the case at bar the court points out that the contract is substantially different in terms from the one in the cited case. Further, there is no reference to any subject matter extraneous to the contract that excludes the idea that the seller was at liberty to cease his manufacture, regardless of the wishes of the buyer.

Hence the judgment that the contract was unenforceable.

Famous Trademark Case Reversed

Highest Court Rules Foreign Maker Cannot Compete With Assignee of His Mark

In the now famous trademark case of A. Bourjois & Co., Inc. vs. Katzel, the United States Supreme Court has reversed the decree of the Circuit Court of Appeals (43 Sup. Ct. 245).[1] The facts of this case are briefly set out as follows: In 1913 A. Bourjois & Cie., E. Wertheimer & Cie., Successeurs, doing business in France and also in the United States, sold to the plaintiff their business in this country, with their good will and their trademark registered in the Patent Office. The plaintiff since its purchase has registered them again and goes on with the business that it bought, using substantially the same form of box and label as its predecessor and importing its face powder from France.

The defendant bought a large quantity of the same powder in France and sold it here in the French boxes, which closely resemble those used by the plaintiff. The court said there was no question that the defendant infringed the rights of plaintiff unless the fact that defendant's boxes and powder are the genuine product of the French concern gives her a right to sell them in the present form.

In giving its reasons for holding that plaintiff's rights were infringed by the transactions of the defendant the court says that after the sale of their business good will and trademarks in the United States the French manufacturers could not come into the United States and use their old marks in competition with the plaintiff. That proposition is founded on the trademark act of Feb. 20, 1905, section 10, authorizing assignments. Further, it says that if for the purpose of evading the effect of the transfer it had arranged with the defendant that she should sell with the old label, it would be plain that the arrangement must fail, but there was no such conspiracy in this case. "The vendors," the court says, "could not convey their goods free from the restriction to which the vendors were subject. Ownership of the goods does not carry the right to sell them with a specific mark. It does not necessarily carry the right to sell them at all in a given place."

Removal of Carbon From Liquids

BY J. BENNETT HILL
The Barrett Co.

In the use of decolorizing carbons in the recovery of gasoline used in dry-cleaning it is often desirable to remove the carbon by settling alone and so avoid filtration. While the bulk of the carbon settles readily, there is a small amount of very fine material that settles only very slowly. This can be removed conveniently by making use of the dirty soap in the gasoline to carry it down. Where the gasoline is not distilled, this soap is normally removed by a treatment with a solution of caustic soda which precipitates it out. If the treatment with decolorizing carbon is given before this soap removal, the bulk of the carbon settled out, and the settled liquid treated with caustic soda, the fine carbon is carried down by the gelatinous soap precipitate, leaving a perfectly clear gasoline.

Possibly this same general idea might be of value in other industries.

Stirrer Efficiency

Who Said Paddle Stirrers Were Not Efficient?—Read This

The article by W. L. Badger and his two co-workers which appeared in the Dec. 13 issue of *Chem. & Met.* was exceedingly interesting to me. The subject "Stirrer Efficiency" has received very scanty study throughout the industry and the amount of misinformation on the subject is great. I recall one incident from personal experience which may be of interest.

Some time ago it was essential for purposes of experimentation to have a wooden tank stirred somewhat rapidly. There was in the plant a tank with an ordinary type of paddle stirrer. It was not even shaved off at an angle of 5 deg., as was the case with Professor Badger's tank, but consisted of a 4x4 tapered slightly to the end and bolted to an upright shaft. Two such arms pointing in opposite directions at the bottom, and two more arms at a 90 deg. angle from the other two, situated 18 in. above the lower arms, made up the whole stirrer. The tank happened to be filled at the time with a finely divided white precipitate suspended in water, and since there was considerable doubt as to the efficiency of the stirrer in question, it was decided to make some tests on the tank as it was. To do this the stirrer was started and when the tank was apparently in full equilibrium 12 gal. of strong solution of victoria blue was dumped in. Six samples of the charge were taken at various parts of the tank, three immediately after dumping in the dye and three at the end of 3 minutes' stirring. The dyestuff gave the liquid a distinct blue color and there was no difficulty whatever in distinguishing the samples which had been in contact with the dye from those which had not. The first samples showed very varying colors from white to very deep blue. The second set of samples were uniform both as to appearance of the unfiltered samples and examination of the filtered solutions. In other words, the tank was stirred completely within 2 minutes. Doubtless if we had started to stir at moment of adding the dye the time would have been longer. This seems to confirm Professor Badger's interesting conclusion that paddle stirrers are surprisingly efficient.

To the Operating Man, Be He Executive or Subforeman

This department will depend for its healthy growth upon your contributions. No man or group of men can supply the raw material adequately. It must represent the experience of all of the men in our industries. If you will contribute one short item from your operating or management experience, you will help to build an invaluable, interesting storehouse of material which will help you, your company and the industry. For every idea you give, you'll get a thousand.

How about it? Forget this "I can't write well enough" excuse. Anyone detected trying to put on literary dress clothes in this department will be prosecuted to the fullest extent of the law.

The Great k_0 Mystery

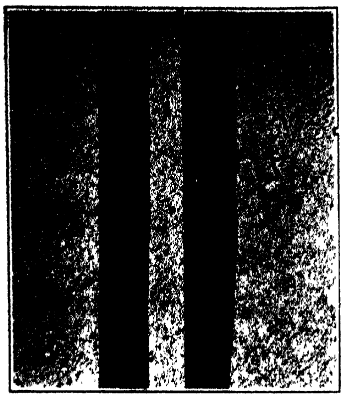
Errors in the Calculation of the Rate of Heat Transfer

Everyone who has had to do with the installation of evaporators or stills or cooling coils has undoubtedly used the following formula:

$$A = \frac{Q}{k_0 h t_m}$$

By this it is possible to calculat the heating or cooling surface neces sary for the particular piece of equip ment in question. A, of course stand for the area or surface required, is the coefficient of heat transfer, is the total heat lost or gained durin the operation, h is the number hours which is required for carr ing out the operation, t_m is the me temperature difference or the te perature gradient in degrees Fahre heit.

The calculation or estimation of is a somewhat inaccurate perfor ance, as it depends on a number rather indeterminate quantities. C ductivity is the reciprocal of res ance and the resistance to heat f in the case of a liquid to liquid tra fer through a pipe would be ec to the resistance of the water film the metal pipe plus the resistance the metal itself, plus the resista of the liquid film on the outside the pipe. Of course the total re ance varies with the rate of flo cooling water, the thickness of metal, surface films or deposit the metal pipe and many other th In other words, the value of k_0 i



Gypsum coated (on left) and clean copper tubing. Why k_o varies

a mathematical certainty, even though it is a so-called constant.

All this serves as an introduction to a specific example of a variation in k_o which has come to the writer's attention. Upon calculating k_o from the best data possible, a value of 230 was obtained, and from this was estimated a total area of heating surface which amounted to about 72.4 sq.ft. A recheck of these figures by another engineer taking into account some experience which he had had with the liquid in question gave an estimated value of 30 for k_o and a consequent value of 555 sq.ft. There followed a series of tests in the plant and in it conditions were developed from which a value for k_o was calculated. This value was found to be in the neighborhood of 60.

The photograph herewith, presented illustrates as well as anything can the reason why any calculation of the rate of heat transfer is practically impossible unless some previous experience with the solution can be relied on, or unless the liquid remains clear and does not deposit on the pipes.

Restoring Steel Barrels

How the Welding Outfit Can Be Utilized to Keep the Scrap Pile Empty

The use of oxy-acetylene welding for reclaiming leaking and damaged steel barrels is recommended. Slightly defective containers that would otherwise soon become worthless scrap can be reclaimed so that they may be re-used or resold by a few minutes' skillful application of the welding torch.

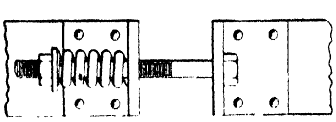
Used metal barrels that are not obviously beyond repair are first steamed and thoroughly cleaned inside and out, an essential operation to prevent possible ignition of explosive gas mixtures when containers have been used for oils, etc. They are then tested under pressure to locate any damaged sections, and those in need of repair are segregated, while the rest are painted and finished for resale.

Welding the damaged barrels is comparatively simple. The testers mark the leaky sections for the oxy-acetylene operator, who welds on an average of 40 barrels and drums a day. Some, of course, require more work than others, but it is only rarely that the damage cannot be repaired with the blowpipe. It has been found that rather than using drawn iron welding rods, ordinarily used on light sheet iron, better results can be obtained by using a bronze filler rod. Quicker, cheaper and better work can be done with the bronze rod, since bronze has a lower melting point and can be more easily handled than drawn iron. As the repaired barrels are painted, the initial bright color of the bronze weld is no objection.

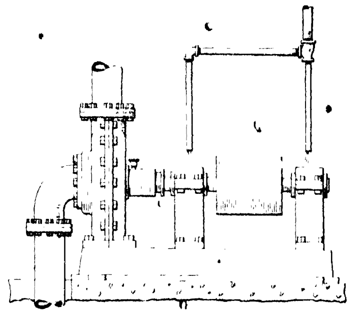
Regardless of whether the damage consists of a split seam or crack, the barrels are restored through oxy-acetylene welding to as serviceable a condition as those which are received undamaged. Even if a section of the side is missing, it may be satisfactorily patched with a piece of scrap steel sheet. After welding, the repaired barrels are tested a second time before they are painted and stored for future sale.

Spring Kiln Hoops

The alternative contraction and expansion of brickwork in kilns, chimneys and flues exposed to intense heat at intervals necessitates adequate provision against loosening and collapse. This provision usually takes the form of steel hoop bands, held together by bolts. During periods of high temperature, these are placed under considerable strain; when low temperatures are reached again, the contraction of the brickwork is likely to result in the slippage of the hoops and the collapse of the structure. To minimize danger from this cause it has been found an advantage in some instances to equip the loops with heavy springs, as shown in the accompanying cut. If desirable, each band may be provided with two bolts and two springs, to equalize the strain.



SPRING KILN HOOP



Water pipes in position to protect bearings from corrosion

Bearing Corrosion

A Simple Method of Preventing Corrosion of Centrifugal Pump Bearings

Centrifugal pumps are very frequently used to pump materials which are distinctly corrosive to the rotor and shell, but more particularly to the bearings. Stuffing boxes do not seem to keep the bearings of even the overhung type of pump from being chewed up with certain types of liquids.

A crude but effective method was worked out to eliminate to some extent the excessive corrosion which in the case of one strongly alkaline liquor was very great. It meant daily attention to the bearings and frequent recasting. A small stream of water was allowed to flow on the outside casing of the bearing. This does two things. In the first place, it keeps the bearings cool and thus cuts down chemical action (on the principle that the rate of reaction is halved for every 10 degrees of temperature drop). In the second place, and more important, the water dilutes the corrosive liquid to an extent that makes it innocuous and non-corrosive.

The accompanying diagram shows the way it is done. Small water pipes are run down to a point just a few inches above the bearings and hardly more than a dribble of water is needed.

In actual, traceable results this stunt was convincing. The life of the bearing was increased by from three to four times and with the alkaline liquor which had to be handled that made a very appreciable difference—a difference which showed upon the mechanics' payroll.

Machinery and Appliances for Production and Control

Equipment News

From Maker and User

Materials and Accessories for Chemical Industries

Pump Valves

Users of pumps will be interested to know that some improvements in pump valve construction are announced by the Worthington Pump & Machinery Corporation, of New York. An entirely different form of valve has been perfected which, when applied to service conditions that have been hard for the older standard valves by causing them to cut and to leak, will eliminate the difficulties. It therefore increases the average pump efficiency, decreases the cost of pumping, and continually maintains the capacity of the pump at its maximum point.

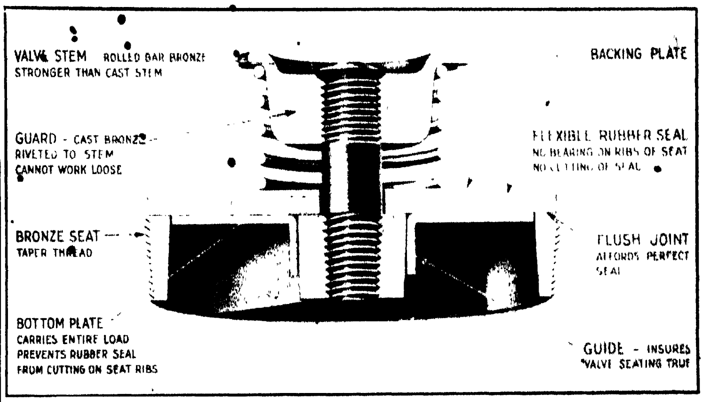


FIG. 1—NEW WORTHINGTON VALVE

Every user of pumps knows of the money loss taking place every day due to leakage through the pump valves when used for severe service conditions. This has led one prominent manufacturer who makes pump valve rubbers as well as other mechanical rubber goods to say in one of his pieces of advertising literature:

"It is a fact that there is more real economy—more actual saving of money—in the use of a first-quality pump valve than in any other one item in the entire mechanical rubber line. We are absolutely sure that this is true."

After many years of building and operating pumps the Worthington engineers now claim that the principal cause of leakage is traceable to the excessive wear on the rubber, which while negligible in some cases is often quite bad. Thus, Fig. 2 shows a photograph of a hard rubber valve after 3 months of particularly hard service. Cracks and cuts caused by the valve seat and by the radiating ribs are plainly visible. Fig. 3 shows a medium rubber also after 3 months of unusually difficult service. It is plain that the only way positively to prevent leakage with valves in this condition is to remove the rubbers and replace them with new.

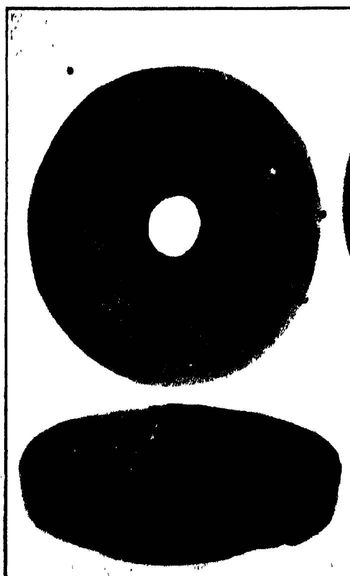

FIG. 2—HARD RUBBER VALVE AFTER 3 MONTHS' HARD USE

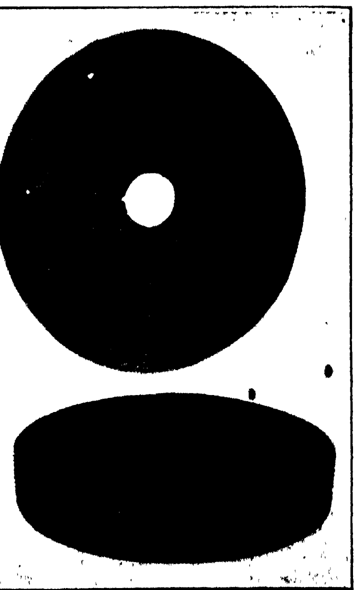

FIG. 3—MEDIUM RUBBER VALVE AFTER 3 MONTHS' HARD USE

To overcome this rapid and costly wearing, cutting and cracking action, there has been evolved the new type of valve shown in Fig. 1, known as the Worthington "Seal" valve for use when the conditions are too hard for the ordinary form of valves now in standard use.

This new valve assures absolute tightness when closed, because, as will be noted, the rubber used is flexible and will always seat perfectly both at the hub and outer rim, its inner and outer seats, and so keep tight. Age and continuous usage do not cut grooves or cause cracks, as demonstrated in Fig. 4, which shows a flexible rubber seal used for a year in this new type of valve. At the end of the year there was no visible wear; there was no leakage; renewal was of course unnecessary; and there was no cost for repairs.

The simplicity of this valve is evident on inspecting Fig. 1. There are no screws, no bolts, no rubber rings, no nuts, no bushings, no rotating elements. The special new feature that makes this valve good for hard service is the rubber valve proper. When the valve is closed the middle seat carries the entire

load and prevents the rubber seal from cutting on the seats or ribs. This bottom plate moves up and down with the rubber, and so not only acts as a middle seat but helps to keep the rubber valve in shape even when open. Thus all mechanical functions requiring strength and wear resistance are cared for by metal parts. The flexible rubber acts only as a seal against leakage. It will be noticed that the top of the rubber seal is protected by a thin "backing plate," which keeps the rubber seal flat and prevents any possibility of wear from contact with the spring.

All moving parts are light but made amply rigid. The lightness assures a smooth, quiet-running pump. The rigidity prevents the distortion that results in leakage. It is not expected that repairs or replacements will be often required, but the construction makes this easy when it does become necessary, and the cost of any possible repairs will be low because of the simplicity and inexpensiveness of all parts.

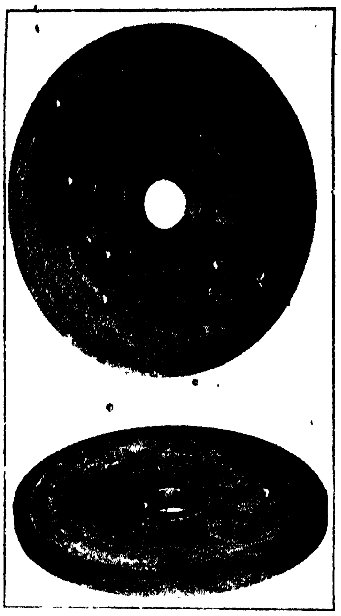

FIG. 4—NEW VALVE AFTER A YEAR'S USE

Requirements of a Refractory Mortar

By Robert F. Lindsay
Research Department, Denver Fire Clay Co.

The apparent need of a better refractory mortar for laying fireclay refractories has resulted in the introduction of a number of so-called refractory cements of varying worth. After 2 years' study of refractory mortars under furnace conditions, the Denver Fire Clay Co., in perfecting its Hi-Fire Bond, found there were certain requirements necessary to the production of a satisfactory bond. A discussion of these essential qualities will be of interest to every user of refractories.

The first specification of a refractory mortar, to be used within the temperature range of a No. 1 firebrick, is that it should be refractory—in other words, having a melting point close to that of the brick with which it is used. Fireclay mortar will stand this test, unless it has been mixed with materials such as the low fusing loams to reduce its shrinkage or cause it to fuse to the bricks; then its value as a refractory mortar is lost. This same fault is found in many of the trademarked cements. To eliminate shrinkage and obtain a cold bonding strength, large quantities of foreign materials are added, and as a result the most important requirement—refractoriness is sacrificed.

Hardening in the cold is of no especial advantage, and should be avoided unless it can be accomplished without eliminating some of the more necessary qualities. Gross misstatements as to the melting points of some of the specially prepared refractory mortars has led to the distrust by many users of all refractory mortars. One refractory cement tested recommended by the manufacturer for use up to 3,300 deg. F. melted at 2,300 deg. F. Unless a mortar has the necessary high melting point the bond it forms is caused by a slag forming between the brick. The result is that under a continued high heat the mortar will flow from the joints, scoring the wall and leaving the joints open to the action of the flames. Ashes and clinkers will readily cling to the slag, further reducing the resistance of the wall. Settling and distortion of the wall under continued heat will also result and in arch construction or where there is a shearing action on the joint the brick will slip out of place. A mortar that is refractory and will sinter into a mass similar in properties to the brick itself is the desired one. It is not a strong, hard joint in the cold that is wanted, but a hard, refractory bond under heat.

A good milled fireclay, although of the same refractoriness as the firebrick, loses its value because of its high shrinkage. This causes the joints to become loose and all the ill effects of a loose setting will result. A satisfactory mortar should have a low shrinkage so that it will stay put. Again, this should not be accomplished by the formation of a slag, for refractoriness must be maintained.

The expansion and contraction of the mortar in relation to the brick are important. They should be the same or approximately those of the firebrick at varying temperatures, otherwise conditions nearly as bad as those obtained from using a mortar with a large shrinkage will occur. When silica is used as a base for the mortar, spalling and loose joints usually result, because its expansion and contraction are not the same as the brick. One of the methods used to correct this fault (and silica is used a great deal as a base because of its low cost) is to use basic fluxes, but here again the slag method of bonding is wrongly introduced.

Not only should the physical properties of the bonding material be like that of the brick but the chemical properties should be similar, having the same resistance to the furnace gases, ashes, etc., with which the brick might come in contact. A mortar that fires to a body similar in structure to the refractory bodies with which it is used and of similar chemical qualities will best meet this requirement.

In attempting to reduce shrinkage and maintain refractoriness we had difficulty at first in producing a mortar that possessed workability. A cement, though otherwise good—that is, sandy in nature—lacks plasticity and with it the desirable thin well-filled joint cannot be made. Uneven laying and waste of material also result. The wet prepared cements can be easily used in making thin joints, and they usually harden in the cold, but this hardening takes place not only in the joint but in the mortar box, on the workman's hands and clothes and often in the containers, causing loss of material and dissatisfied workmen. Although a thin joint is recommended, it is at times necessary to use heavy layers of mortar, and a wet prepared mortar, if suited for making thin joints, often cannot be used for the heavier joint unless some foreign material is used to thicken it. Good foreign material to add is not always available, and if the wrong material is used another deleterious factor is introduced.

Good working qualities not only assure a better brick-laying job but a considerable saving of material.

A "Gentlemen's Agreement" Against Technology?

To the Editor of Chem. & Met.:

SIR—There are many members of the chemical profession whose careers are threatened today by a certain vicious practice that appears to be growing in American industry. This practice consists in what is called a "gentlemen's agreement" among manufacturers in a certain industry not to employ a technical expert who has left the employ of a concern engaged in the production of the same or a similar product or at least not without the permission of the last employer. I believe there is just such an agreement in existence among certain manufacturers of artificial silk, certain dyes, abrasives, caustic soda, etc. It probably originated in the idea once entertained by many that valuable trade secrets would be carried away by the technical expert who would then sell them to a competitor and thus enable him to produce a better or cheaper article.

The probable effect on the manufacturer has been for him to increase research to a certain point, and then stop and wait for his competitor, in the meantime enjoying a feeling of security in the possession of the results of this research. The effect on the chemical profession, however, has been literally to enslave many individuals in positions at salaries frequently far incommensurate with the profitable results they achieve. They cannot help themselves, because their experience is specialized and cannot be sold on the open market due to the "gentlemen's agreement" among the possible employers. The technical man is thus often penalized for having given meritorious service and he has no alternative but to continue the drudgery or to leave and enter work in a different line—work in which his experience will probably be of little use. Actually in this event the original employer has locked up the expert's experience where it will be of practically no value to himself or to the public.

Any solution to this vital problem in ethics which has not the good of the public and justice at heart would, of course, be wrong. On one hand we have increased the desire of the manufacturer for research, and on the other we have killed or limited the incentive of the man who does the research through a highly arbitrary agreement that may limit his rewards, his success and his career. Notwithstanding the fact that genius exacts its own reward, the majority of even so learned a profession as ours are not geniuses. And the effect on the public is indirectly, if you wish, to pay the bill for research, which, if it has been done at all, has not been as fruitful in benefits to mankind as it would have been were a proper incentive given the researcher. Such a stimulus would follow only from an opportunity to sell his special abilities on a free and open market.

It is all right to have trade secrets. It would be well if there were more real ones and less imagined ones. But when trade secrets limit the progress of the men who have created them, they limit the public good that comes from such progress; and any agreement, gentlemanly or ungentlemanly, is vicious which allows this state to exist.

Buffalo, N. Y.

Corrosion of Rust-Proofed Iron and Steel

To the Editor of Chem. & Met.:

SIR—The article by W. P. Wood on "Corrosion of Rust-Proofed Iron and Steel" in your April 30 issue contains conclusions which I feel are hardly justified by the data furnished. I refer to the statements made regarding chlorine in tap water, particularly to the assertion that the tap water he used contained dissolved chlorine. In determining the chlorine-consuming capacity of sewages for the city of Cleveland, done by the city's engineering department in 1919-1921, controls were always used of tap water and distilled water. We invariably found that tap water (which had been previously chlorinated by the city's water department) has a chlorine-consuming capacity as great as and usually greater than its oxygen-consuming capacity, given the same time and equal molecular amounts at the start. Our data indicated a fairly close relationship between the two. The tap water he cites had an oxygen-consuming capacity of 2.7 parts per million when he received it; therefore I feel quite sure that any chlorine which had been introduced at his local water plant was completely and chemically dead by the time it reached him, for we found that organic matter oxidized by chlorine is exceedingly stable. Furthermore, a dosage of chlorine sufficient to saturate the consuming power of the water and leave an analyzable excess at the consumer's tap is indeed a rarity.

It is quite likely that the "chlorine" which he lists under "constituents" refers to combined chlorine as chlorides, because a dosage of 7.6 p.p.m. is considerably more than twice as much as is necessary to give a very pronounced taste to water and is probably close to ten times the average dosage. That amount would accomplish 75 per cent disinfection or better in an ordinary city sewage.

Before rightly ascribing to chlorine the differences found in corrosion there should be run another set of samples in an unchlorinated water having the same constituents. When that is done, it is probable that the mineral salt content of the water will be blamed rather than a little chlorine long since dead.

GLENN GREEN.

Pathological Laboratory,
Lakeside Hospital,
Cleveland, Ohio.

To the Editor of Chem. & Met.:

SIR—The writer wishes to point out that his conclusion in connection with the corrosiveness of tap water was reached as a result of the tendency of this water to cause pits in the metal. The importance of this was definitely mentioned in the article. A rigid comparison of weight losses would not lead to this conclusion in all cases, but the pitting was quite evident.

Always granting the possibility of analytical errors and the fact that the figures for chlorine are considerably higher than the average, the case in question is somewhat unusual in that the samples were taken at a point not far from the purification plant. There is admittedly a considerable variation in chlorine content at this point. Further, the nitrogen content of the raw water is very low, and while the chlorine which has been added to the water might be, as it were, "bacteriologically dead," it is very questionable whether it is "chemically dead." The writer has been informed by a member of the laboratory whose duty it was to check this water regularly that positive tests for free chlorine by the orthotoluidin method were obtained within a radius of several miles from the purification plant. There is also on many occasions a pronounced taste to the water.

In conclusion, it might be well to point out that the mineral salt content of this particular water would be practically a negligible factor as far as corrosion of metals is concerned.

WILLIAM P. WOOD,

Assistant Professor of Metallurgical Engineering.
University of Michigan,
Ann Arbor, Mich.

Was It an Impurity?

To the Editor of Chem. & Met.:

Sir—Back in 1880-81 Dr. Edward G. Acheson was at work in the Edison laboratories, pegging away at carbon filaments. In his search for new modifications he undertook to break up carbon compounds by electrolysis. He chose carbon bisulphide, which he put into a test tube, and in this inserted two platinum wires. But the CS_2 would not conduct the current until he had shaken it up with water; then it became a partial conductor, its conductivity increasing as the current passed through it.

While no carbon appeared, he observed occasionally the deposit of small white granules at the bottom of the carbon bisulphide. What were they?

He separated them until he had about half a gram. They were very hard; they made scratches on sapphire.

Another curious feature was that when a granule of the substance at the bottom of the test tube containing CS_2 was brought between the platinum electrodes there developed a flash of light—and then the substance turned black.

The next step was to call, in company with his friend Dr. Edward L. Nichols, on the late Mr. Tiffany at his great jewelry establishment, then on Union Square. Hailing from Menlo Park, they obtained an audience without delay. Mr. Tiffany sent for his diamond expert, who proved to be a tall young man named Kunz - none other than our old friend Dr. George F. Kunz. He said if they would return in a couple of hours he would tell them what they had. But when they returned young Mr. Kunz admitted that he did not know. "It is not carbon," he said, "because it dissolves readily in hydrofluoric acid. But if you can make it in quantity and at a low cost it will be of great use to the world as an abrasive!" This was just 10 years before Dr. Acheson made carborundum.

But what were those granules? Mr. Acheson became assistant chief engineer for the Edison interests in Europe in 1881. In Paris he met an eminent German chemist whose identity has passed into the limbo of forgotten names. He described the experiments to him.

"Hah," exclaimed the eminent German chemist, "here you have another proof that sulphur is not an element. You have obtained, sir, a decomposition product of sulphur itself, which I have long claimed cannot be an element!"

Now we meet another difficulty. The voltage was 104, reduced by lamps in series and the current increased until the lamps glowed a dull red. But 20 years afterward Dr. Acheson tried to produce those same granules from carbon bisulphide in his laboratory. He used all the diligence and all the strategems at his command, without getting a sign of them in a single instance! What was the stuff?

Developments in the Manufactured Gas Field

Attention of Inventors Indicates the Industrial Importance of This Fuel

THE NORMAL PROCEDURE in manufacuring water gas or similar gas is to keep the CO at a maximum and the CO_2 at a minimum, because CO_2 is an incombustible. However, if the carbon were all changed to CO_2, the increased yield in hydrogen would give the gas a higher thermal value, as a study of the thermal reactions will show. In the usual method of water-gas manufacture, a certain per cent of CO will always be formed, however. In this invention of Harold R. Berry of Wilmington, the object is to supply a means for oxidizing all the CO and freeing all the hydrogen. The simplest form is an ordinary water-gas set, to which has been added, directly over the generator, through which the make must pass, a chamber containing a grate. On this grate are placed shavings, strips and borings of, say, steel and iron, or any other suitable substance.

These substances react with the steam to form an oxide, thus releasing all the hydrogen. In its turn, in the presence of CO, the oxide releases oxygen, which reacts with the CO to form CO_2, the scrap being rejuvenated. The chief requirement of this scrap is that it have a relatively large surface

American Patents Issued June 5, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met* readers They will be studied later by *Chem & Met 's* staff, and those which, in our judgment, are most worthy will be published in abstract It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis

1,457,339 Kiln and Burner Therefor. M Bassler, Milwaukee, Wis.

1,457,343—Rubber Mixer or Like Machine. D R Bowen, Ansonia, Conn., assignor to Farrel Foundry & Machine Co., Ansonia.

1,457,351—Air Filter L L Dollinger, Rochester, N Y

1,457,406—Depth and Specific-Gravity Measuring Apparatus C W. Stancliffe, New York assignor to Pneumercator Co, New York

1,457,413—Machine for Treating or Processing Fabrics and Other Goods A Wilson, Elizabeth, N J, assignor to Duratex Corp, Newark, N J

1,457,436—Process of Making Metal Sulphides Henry Howard and E. B. Alvord, Cleveland, Ohio, assignors to Grasselli Chemical Co, Cleveland.

1,457,484—Method of Purifying Acid Liquor. F. C. Atkinson, Indianapolis, Ind.

1,457,498—Process of Making Phosgene. D. B. Bradner, Edgewood, Md.

1,457,503—Method of and Apparatus for the Purification of Water W. M. Cross, Kansas City, Mo

1,457,514—Filtration Chamber. J W. Flower, Detroit Mich., assignor to Michigan Valve Foundry & Engineering Co., Detroit

1,457,521—Powdered-Coal Apparatus A J. Grindle, Chicago, Ill., assignor to Grindle Fuel Equipment Co

1,457,522—Powdered-Coal Apparatus A J Grindle, Chicago, Ill, assignor to Grindle Fuel Equipment Co

1,457,543—Nitrating Aromatic Hydrocarbon S. P. Miller and J. R. Hess, Philadelphia, Pa, assignors to The Barrett Co

1,457,656—Process of Desulphurizing Petroleum and Petroleum Distillates A E Dunstan and E B Thole, Sanbury-on-Thames, England

1,457,676—Process of Making Sulphuric Acid and Apparatus Therefor. F G Stantial, Melrose, Mass, assignor to Merrimac Chemical Co., Woburn, Mass

1,457,709—Explosive C. J Startsböll Lundsgaard, Vejen Denmark

1,457,718—Electric Furnace. I. R Valentine, Erie, Pa, assignor to General Electric Co.

1,457,780—Gas-Fired Melting Furnace. H O Loebell, New York, assignor to Doherty Research Co, New York.

1,457,786—Recovery of Gasoline From Natural Gas, etc E S. Merriam, Marietta, Ohio

1,457,791—Process of Making Succinic Acid J F Norris and E O. Cummings, Cambridge, Mass.

1,457,793—Process for Obtaining Sulphur R. S. Perry, Cave Springs, Ga., P. W. Webster, Pelham Manor, and V. K. Boynton, New York, assignors to Perry & Webster, Inc.

1,457,794—Settling Apparatus W. E Piper, New Canaan, Conn., assignor to Dorr Co., New York.

1,457,803—Apparatus for Separating Solids from Liquids. A. J. White, San Antonio, Tex.

1,457,810—Screening Apparatus P J Alwart, Chicago, Ill.

1,457,811—Displacement Element for Liquid Containers. L. E. Baker, Fort Wayne, Ind., assignor to Wayne Oil Tank & Pump Co, Fort Wayne.

1,457,835—Process for Producing Catalytic Material for Hydrogenating Unsaturated Oils and Fats to Harden Them J. P Harris, Chicago, Ill, assignor to Allbright-Nell Co., Chicago

1,457,848—Agitator T. Mojonnier, Oak Park, Ill., assignor to Mojonnier Bros Co, Chicago.

1,457,865—Apparatus for Comminuting, Refining, and Triturating Paper or Cardboard Pulps K. A. Thorsen, Grenoble, France

1,457,877—Recovery of Ammonia L E. Doty, Elyria, Ohio.

1,457,915—Method of Making Paper Pulp B S Summers, Port Huron, Mich

1,457,934—Method of Making Precipitated Barium Sulphate and Sodium Sulphydrate J B Pierce, Jr., Charleston, W. Va.

1,457,935—Method of Making Precipitated Barium Sulphate J. B. Pierce, Jr., Charleston, W Va.

1,457,941—Cooler for Reclaimed Liquor and Gas in Paper-Pulp Processes. G F Shevlin, Glens Falls, N. Y.

1,458,001—Method of Burning Sulphur A. T. Prentice, Somerset West, Cape of Good Hope, South Africa.

1,458,016—Method of Treating Siliceous Ores. G. H. Wigton, Eureka, and S. M. Seddon, Salt Lake City, Utah.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

—that is, that it be finely divided. (1,453,655, Harold R. Berry, assignor to Petroleum Research & By-Products Co., Wilmington, Del., May 1, 1923.)

Retort for Low-Temperature Gas Making

The efforts along the line of low-temperature carbonization and gas manufacture have been of increasing interest. One of the pioneers in this field was the International Coal Products Corporation. It is now putting forward a patent covering a new type of primary retort in connection with its well-known process.

This particular design, the patent of Charles E. Richardson (1,454,338, Charles E. Richardson, assignor to the International Coal Products Corporation, Richmond, Va., May 8, 1923), is concerned with the structural details of this type of retort. It claims to improve the support of the retort, to improve the design so that it may be more easily assembled and disassembled, and to improve the arrangement of both burners and flues.

Coking Non-Coking Coal

One of the greatest desiderata of the byproduct coke and gas field is an oven that will coke certain high-volatile coals of low agglutinative power and give good results. A solution of this difficulty is offered by Paul Goffart (1,455,527, assigned to Belgian-American Coke Ovens Corporation, Wilmington, Del., May 15, 1923).

This patent claims that in order to convert coal of this type into dense coke, distillation must be rapid at the top of the charge, thus preventing the formation of sponge coke at the top. To accomplish this result, the vertical heating flues are divided into pairs of adjacent flues. The fuel gas is admitted at the top at a point between the flues of each pair. The air for supporting combustion travels upward in one flue of each group and the gases of combustion pass downward in the other flue of the group. From time to time a reversal occurs as between these two flues. Means is provided for regulating both the length and the intensity of the flame. In this way a controllably higher heat may be maintained at the top of the oven than elsewhere.

Doing Away With Reversing Engines

Designers of coke ovens have long sought for a means of eliminating the reversing engines. The expense and added complication due to these mechanisms and the repair cost which they entail are sometimes a serious burden.

As a means of accomplishing this end William E. Roberts has obtained a patent (1,453,605, assigned to Foundation Oven Corporation, New York, May 1, 1923) on an oven of novel type. In this oven the flues are arranged in pairs, vertically. Gas and air enter at the bottom of one of the flues of each pair, burn up this flue and down the next, the products of combustion passing out through the waste gas ducts. The combustion flues of one tier of flues are adjacent to the waste gas or downward flues of the next tier, which is designed to assist in heat distribution.

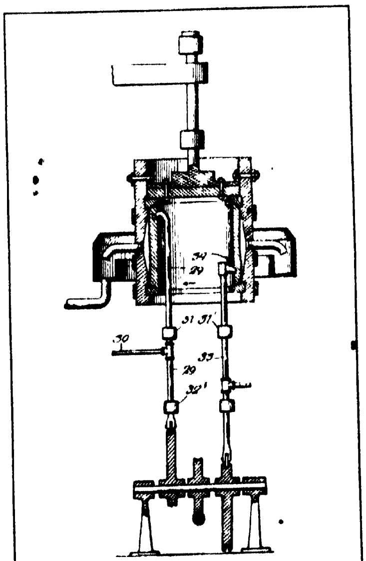
The waste gas ducts are common for all the waste gas flues of one tier of flues. The air passages for admitting the air are located on the sides of the waste gas ducts and their parallel length is sufficient to preheat the entering air thoroughly.

It will be noticed that this design of oven permits continuous combustion without reversal and does away with regenerators.

Patented Ideas in Chemical Engineering Equipment

A Continuous Centrifuge and New Plate for Column Stills Are Featured in Recent Patent Specifications

Broadly speaking, the use of centrifugal force in the separation of liquids from solids is a comparatively old process, although advances are being made continually in the equipment for applying this useful principle. Recently the trend has been toward developing and perfecting a continuous centrifugal separator, notwithstanding the fact that in certain of the chemical industries "batch" operation is sometimes of importance. For instance, it is frequently necessary to remove a precipitate from a mother liquor, and then in order to obtain the desired degree of purity the solid must be washed free from the mother liquor while it is still in the rotor. A separator invented by Sylvester S. Howell and assigned to the United Chemical & Organic Products Co., of Chicago, takes advantage of both of these requirements, since it is suitable for either continuous or intermittent operation. A feature of this piece of equipment is the arrangement of introducing the material to be separated and the removal of the solid matter through the open bottom of the rotating cylinder or rotor. The solid may be conveniently removed through this open bottom of the rotor while it is in motion and the materials to be separated can be introduced into the cylindrical rotor without stopping it, thus rendering the separating operation continuous.



Two points of interest are the methods by which the material to be separated is fed into the centrifuge and the provision for withdrawing the solid cake or residue. Referring to the accompanying figure, it will be noted that the material from which the liquid to be separated comes in through the supply pipe 29 and the hose 30. This pipe is supported on bearings 31 and 32 and can be moved in a vertical direction as the material is sprayed on the filtering lining 24 while the latter is in rotation. The pipe 33 is provided with a nozzle through which compressed air is forcibly projected toward the filtering lining in a direction opposite to its direction of rotation. This nozzle produces a thin blade or jet of compressed air which is discharged upon the interior of the centrifugal rotor. By the operation of this sort of nozzle, the filter cloth or lining, when such is used, is maintained quite free of material, thus increasing the filtering capacity of the machine. This has the advantage over a mechanical scraper plow in that it is not possible with the latter to run very close to the inside surface of the cloth for fear of rupturing it. The pneumatic plow, on the other hand, is remarkably flexible. (1,453,678, issued May 1, 1923.)

A Still Plate With Check Valves

An unusual feature in the construction of diaphragm plates for a column still is brought out in a recent patent by Ralph H. Twining, of Marquette, Mich. (1,453,735, issued May 1, 1923.) Instead of the usual cup or sieve construction, provision is made for a diaphragm plate having a large number of perforations, in each of which is a rivet-shaped check valve. This valve consists of an ordinary rivet having its head normally resting on the upper surface of the plate and its stem projecting through the perforation. The pressure of the rising vapor in the column causes the heads of these valves to be lifted from their respective plates and the vapor is permitted to pass through the perforation. If the pressure of the vapor is

variable over the different portions of the plate, the valves in any portion not subjected to sufficient pressure will not be raised, as each of the valves is entirely independent of the other in its action. This is particularly important, as it prevents the escape of the fluid at points where the pressure is inadequate to support it.

Fighting Oil Fires

In fighting oil fires by means of a fire-extinguishing foam, it has been repeatedly found that when an explosion occurs in the oil tank—this being generally preliminary to the beginning of a fire where lightning is the cause—the roof or tank top is forced or blown off violently. The mouth of the foam delivery system attached to it is usually broken or put out of use, thus resulting in the failure of the fire-extinguishing apparatus. To overcome this objection, the delivery system for the foam is sometimes placed in the side of the tank above the "normal" oil level. This sort of installation, however, has the disadvantage that the normal oil level is never constant, and that a rise above the predetermined level will often result in the oil leaking into the foam delivery mixing chambers. Willis D. Witter, of Roselle Park, N. J., in a patent assigned to the Foamite Fire-Foam Co., of New York, retains the type of installation in which the foam is allowed to enter through the tank roof or top, but at the same time he makes provision so that in case of the violent removal of the tank top by an explosion, it will not disrupt or break down the foam delivery system. (1,454,839, May 8, 1923.)

To Facilitate Pipe-Line Pumping

In pumping heavier grades of petroleum through pipe lines, it is often found that the oils are so heavy and viscous that their handling is extremely difficult. In fact, some grades of oil are so heavy that it is practically impossible at ordinary temperatures to pump them through the pipe. Various means have been used to make the oil more fluid. John P. Persch, of Houston, Tex., has patented a process of agitating the oil in a cylindrical chamber connected with the pipe line and introducing into the oil during the process of agitation a strong blast of air. There is formed an emulsion of air and oil of considerably lower specific gravity than the original oil. If the air has previously been heated to a suitable temperature, it is claimed that it will have the effect of breaking up the hydrocarbon molecules to a certain extent and thus make the oil permanently more fluid and that it will not return to its original viscous state. The agitating apparatus consists of mechanically operated paddles attached to a central shaft. (1,454,485, issued May 8, 1923.)

Important Articles In Current Literature

More than fifty industrial technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem & Met* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers Those that are of unusual interest will be published later in abstract in this department, but since it is frequently impossible to prepare a satisfactory abstract of an article this list will enable our readers to keep abreast of current literature and direct their reading to advantage The magazines reviewed have all been received within a fortnight of our publication date.

Men in the Profession

JOHN DAVIS has been selected to take charge of experiments being conducted by the Board of Helium Engineers working under the Bureau of Mines on the government reservation at Fort Worth, Tex.

Prof. GRAHAM EDGAR sailed for Europe on June 11. While in England he will be one of the American representatives at the International Union of Chemistry.

J. N. GUNN of New York has resigned as president of the United States Tire Co. and vice-president of the United States Rubber Co., the parent organization. C. B. SEGER, president of the United States Rubber Co., has been elected to a similar position with the tire division, succeeding Mr. Gunn.

WILLIAM M. KEELING, who was graduated from the Missouri School of Mines in May, is now chemist with the American Smelting & Refining Co.'s lead refinery at Omaha, Neb.

EDMUND LEAVER, who has been serving as superintendent of the Bureau of Mines experiment station at Tucson, Ariz., has been assigned to the superintendency of the precious metal station at Reno, Nev. S. P. HOWELL, the bureau's specialist in blasting and explosives, has been made superintendent of the Tucson station.

R. WALTER LEIGH has been elected vice-president of the American Beet Sugar Co., New York, succeeding the late H. T. Oxnard.

J. M. LESSELL, research engineer, Pittsburgh, gave the principal address at the meeting of the local chapter of the American Society of Steel Treating, at the William Penn Hotel, June 5, on the subject "Methods of Static and Dynamic Testing of Metal."

CHARLES A. MEADE, vice-president of E. I. du Pont de Nemours & Co., Wilmington, Del., has resigned to devote his time to private enterprises. He became connected with the development department of the company in 1915, and in 1919 was elected vice-president and director.

E. C. MOFFETT, formerly with the Ideal Disinfectant Corporation, Woodbridge, N. J., is now with the Cyanide Co., Warners, N. J.

THOMAS W. STREETER has been elected chairman of the board of directors of the Simms Petroleum Co., N. Y., to succeed Harry Bronner, resigned.

W. H. WALKER, of the U. S. Department of Commerce, is in California conducting a survey of the agricultural needs of that state for nitrogen compounds.

Obituary

CLYDE MITCHELL CARR, until recently president of Joseph T. Ryerson & Son, Inc., died on June 5 at his residence in Chicago. Mr. Carr was born in Will County, Ill., July 7, 1869. For 12 years he was president, but for the last 4 years had been unable to take an active part and last January resigned as president, although continuing until the time of his death as a member of the board of directors.

Calendar

AMERICAN CHEMICAL SOCIETY, fall meeting, Milwaukee, Wis., Sept. 10 to 14.

AMERICAN ELECTROCHEMICAL SOCIETY, forty-fourth meeting, Dayton, Ohio, Sept. 27 to 29 (dates provisional).

AMERICAN ELECTROPLATERS SOCIETY, eleventh annual meeting, Providence, R. I., July 2 to 5.

AMERICAN GAS ASSOCIATION, annual convention, Atlantic City, Oct. 15 to 20.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, summer meeting, Wilmington, Del., June 20 to 23.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS, iron and steel exposition, Buffalo, N. Y., Sept. 24 to 28.

AMERICAN SOCIETY FOR TESTING MATERIALS, twenty-sixth annual meeting, Chalfonte-Haddon Hall Hotel, Atlantic City, June 25 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH), New York, Sept. 17-22.

NATIONAL SAFETY COUNCIL, twelfth annual safety convention, Statler Hotel, Buffalo, Oct. 1 to 5.

Industry and Trade

Current News and Market Developments

Summary of the Week

Imports of chemicals and allied products in April were valued at $12,276,199.

Treasury Department has revoked anti-dumping order against calcium carbide from Province of Quebec, Canada.

Annual census of coal-tar products completed by Tariff Commission and will be sent to public printer about June 20.

Production of industrial alcohol for 9 months ending March, was larger than in fiscal year ending June 30, 1921.

Canadian decree prohibits manufacture and importation of oleomargarine in Dominion.

Sales of new crop crude cottonseed oil have been made on a basis of 7c. per lb. f.o.b. mills.

Resale offerings of phenol reached the market and the price declined to 42c. per lb.

Supreme Court denies application to review the decision in the case of the Mennen Co.

Case of government against the Chemical Foundation weakened by testimony of Polk. Court holds much evidence presented by government irrelevant. Defense to ask dismissal.

Dr. Samuel W. Stratton inaugurated president of M.I.T. with impressive ceremonies in which eminent scientists participated.

Canada to survey domestic heating problem from by-product coke.

Imported copper sulphate shows slight recovery from recent weakness.

Permanganate of potash sold at new low and is very irregular in price.

Export demand for caustic soda is very quiet and prices are subject to shading.

Several crushers of linseed have caught up on deliveries of oil and the market is approaching a normal supply basis.

Syndicate in Control of German Potash Industry

ADVICES coming from the American Consulate at Frankfort-on-Main state that rumors of attempts by American and Dutch interests to obtain control of German potash properties have brought out discussions on the potash situation in Germany. A prominent publication in Frankfort says that the object of the publication of these rumors is probably to arouse German interests in potash shares and to increase public confidence in the industry. Whenever the danger of foreign control is really felt, it is stated, preference shares are issued and taken over by the companies' members, each share granting the right of 10, and in some instances as many as 25 votes.

Falling off in orders in the German potash industry which began in December, 1922, continued throughout the first 3 months of the present year. In February certain quantities of potash were stocked by producers and full production was maintained, but in March the shutting down of several shafts was reported. The German Potash Syndicate complains that a late announcement by the government of price reductions in certain nitrogen fertilizers, accompanied as it was by the statement that a reduction in prices of other fertilizers would shortly follow, has unfavorably affected potash sales. The farmer was led to expect reductions in potash prices which, aside from certain usual summer rebates, it will be impossible for the syndicate to make without cutting prices below cost of production.

Export trade in March is reported to have been satisfactory, but this is declared to be doubtful. When export trade in potash is good, it is pointed out, few complaints of a poor domestic market are heard. The fact that the abolishment of export duties was urgently demanded is said to show that the export situation was not satisfactory.

The Berlin correspondent of the Boston News Bureau in an interesting report says: "German potash industry is very well organized. Its supreme controlling body, the Potash Syndicate, is compulsory in character and disposes of the out-turn of the individual mines according to their productive capacities. Therefore it is the goal of every member to acquire as many mines or mining claims as possible, to sell larger quantities through the syndicate, the more so as the latter also disposes of exportable surpluses. These circumstances have contributed to the creation of large combines, such as the Wintershall - Gluckauf - Sondershausen concern, which disposes of 40 per cent of the total German production; the Salzdetfurth concern, with 20 per cent, Burbach-Krugershall, Gumpel-Heldburg and Ronnerberg.

"The self-government of the industry is represented by the Imperial Potash Council, in which the interests of the farmers, the chemical and other consuming trades, along with those of the producers, are given full scope for all complaints, as in this potash parliament the prices, freights and expenses made up by the syndicate are scrutinized.

"There is another examining body, the object of which is to reduce number of shafts sunk to the needs of the industry, for, despite surrender of 17 big Alsatian works to France, the number of actual works now stands as 208, against 191 at the beginning of the war.

"Production of potash salts shows a big increase over pre-war figures, outstripping 1913 by 2,000,000 quintals annually apart from present Alsatian production of 1,100,000 quintals.

"Competition for the American market has led to conclusion of a contract with the Potash Importing Corporation of America in New York, which is believed to be backed by important American shipping and banking interests. The corporation's agents are to start a lively propaganda campaign among the farmers of the United States in the interest of spreading the use of potash salts as fertilizer. While the French Government grants bounties to exporting Alsatian firms in order to help them to gain a footing in overseas markets, the German Kali-Syndikat seeks to recapture the American market by allowing abatements to the corporation to the extent of 30 per cent or so of invoice amounts.

"The German-American potash contract is to run 5 years. The value of surplus of potash in Germany is calculated at $50,000,000."

Canada Prohibits Manufacture and Importation of Oleomargarine

Prohibition Measure Effective August 31—Expected to Curtail Canadian Demands for Vegetable Oils

THE Canadian Parliament has voted to put an end to the oleomargarine industry in Canada. War-time legislation that permitted the manufacture and sale of oleomargarine in Canada will expire on Aug. 31 this year. That is, the manufacture and importation of the product must cease on Aug. 31, but its sale may continue until March 1, 1924. While it is still possible for the government to bring in new legislation this session that would permit the people of Canada to use oleomargarine products, there is little probability that anything of the sort will be done.

Previous to 1917 oleomargarine was not allowed to be manufactured or sold in Canada. But when the war placed an unusual drain on the food supplies of the world, the Canadian Parliament permitted the manufacture and sale of the product. The main argument behind the agitation, which has been long and vigorous, is that it has been hurting the Canadian butter industry.

The oleomargarine question has engaged the attention of Parliament to an unusual degree this session and has provoked many long discussions as to its merits and demerits. The climax finally came during an all-night session recently. It was the end of an all-session lobby, with the dairying interests carrying on a persistent warfare against the commodity and the oleomargarine manufacturers almost equally active in support of it. It was not a party question, for the discussion saw W. S. Fielding, Minister of Finance, taking a position diametrically opposed to the Prime Minister. The Conservatives and the Progressives likewise were divided. In the last analysis, after 9 hours of strenuous debate, the antis won out by 125 to 54.

Laborites Fight for Oleo

W. F. Carroll of Cape Breton, who comes from a laboring constituency where a good many tons of the commodity are used in a year, put up a determined fight to have its manufacture and sale continued permanently. He argued that there was no more reason for dictating what a person should eat, so long as it was healthful, than there was reason for dictating the kind of apparel he should wear. He was supported by the Minister of Agriculture in the late government, Dr. Tolmie, who went into a microscopic analysis of the whole subject, treating it from the standpoint of palatability and nutrition and from other angles, and, though as a dairyman he would benefit by the prohibition, he upheld the right of the import and manufacture in the natural color.

The Prime Minister contended that the permit was only a war measure, involving a specific pledge to the dairy interests that when the war ended it would be abandoned. On the other hand, Mr. Fielding steered a course directly opposite to his chief, quite discounting the argument of any pledge to the dairymen and maintaining that the issue was on the merits and the vital question whether or not the intelligence of the Canadian people enables them to determine what they want to eat—butter or a substitute.

Butter Coloring Permitted

Dr. Tolmie reminded the House that butter makers were permitted to heighten the color of their butter in winter when it was a light color and low in vitamine contents as compared with summer butter. This gave no indication to the purchaser of the value of the goods in that respect. He further argued that during the war Canadian troops used oleomargarine; British troops used it, and now it was on the regular ration list of both the British army and navy. He urged that only half of the people of the world used milk and it was idle to say that the milk industry would be damaged by oleomargarine. As to cottonseed oil, which was one of the main ingredients of oleomargarine, this was used in salad oils and other edible products. There was much more to fear, Dr. Tolmie added, from the making of inferior dairy products than the making of oleomargarine. Since 1919 there had been 489 prosecutions against butter makers in Canada as against 48 oleomargarine prosecutions.

Arthur Meighen, leader of the Opposition, pointed out that in 1918 the government had permitted the sale of oleomargarine as a temporary measure under the war measures act. This was made plain in the legislation and at the next session the government recommended to Parliament that this temporary measure be continued as such. His own attitude was that the use of oleomargarine should be permitted. He did not see any reason why a genuine food should not be manufactured in Canada if the people wished it. He believed that there should be a fair protective tariff on the product. The United States had a duty of 8 cents against Canadian butter and 8 cents against oleomargarine. Why should Canadian dairymen have to compete against American manufacturers of butter substitutes in the Canadian market?

This action of Parliament is expected to have a decided bearing on importations of various vegetable oils into Canada. Large amounts of coconut, cottonseed, peanut and other oils are used in the manufacture of nut butters and margarines.

Dr. S. W. Stratton Inaugurated President of M.I.T.

Impressive Ceremonies With Many Eminent Scientists Present Mark His Taking Chair

On June 11 the attention of the academic world was focused on M.I.T. Dr. Stratton, former head of the Bureau of Standards, officially took the president's chair of the Massachusetts Institute of Technology at that time. Speakers of note were present to address the large body of faculty, students and alumni gathered at Horticultural Hall, where the ceremonies took place.

Frederick P. Fish acted as master of ceremonies at the inauguration. Major-General George O. Squier spoke with feeling of his 15 years' close association with Dr. Stratton in connection with army problems. For the faculty, Prof. Edward P. Miller greeted the new president, pledging co-operation and firm loyalty. Governor Channing Cox glorified the commonwealth of Massachusetts in having such an institution, with such a faculty, within its bounds. The founders of Technology, Mr. and Mrs. William Barton Rogers, received a tribute from President Emeritus Charles W. Eliot of Harvard. Professor C.-E. A. Winslow of Yale represented the alumni at the ceremonies. He voiced the sincere admiration and respect of that body for the new president of their alma mater and emphasized the immense potentialities of the scientific spirit in solving industrial and social problems. Dr. John Campbell Merriam, president of the Carnegie Institution of Washington, expressed the regret of Dr. Stratton's colleagues there at losing his constant association. He spoke at length of the new president's qualifications, emphasizing the fact that he is a thoroughly constructive scholar. In his own address, to which reference is made elsewhere in this issue, Dr. Stratton stressed the effect of science in the evolution of industry.

Banquet at Algonquin Club

In the evening the new president acted as toastmaster at a banquet at the Algonquin club. Dr. A. Lawrence Lowell, president of Harvard, Prof. Edgar Odell Lovett and Prof. Theodore W. Richards were among the speakers at this gathering. Professor Lovett, of the Rice Institute in Texas, spoke of education in that state. Professor Richards presented greetings from the Royal Society, the Royal Institution and the Chemical Society of London. President Ira Nelson Hollis of Worcester Polytechnic Institute, an old friend of Dr. Stratton, spoke in praise of the man "who, if he can persuade Congress to support the Bureau of Standards, is well equipped to meet Tech's problems."

Professor Allard of the Ecole Normale Supérieure of Paris, Dean Kimball of Cornell, Dr. Zook of the U. S. Bureau of Education and Dean Clark of the University of Illinois also spoke. The prevailing theme both of the day and of the evening is discussed editorially on page 1060 of this issue.

Chemicals on Free List Form Major Part of April Imports

Total Imports for Month Less Than in March, but Larger Than in April, 1922

IMPORTS of chemicals and allied products during April were valued at $12,276,199. Of that amount $8,598,464 represents the value of imports not subject to duty. Imports on the dutiable list totaled $3,677,735. The free list imports are less by $1,500,000 than those in March. There was a falling off of about $150,000 in the total value of imports on the dutiable list. In April of 1922 the value of free list imports was $5,528,218, and of dutiable imports $3,003,094.

The value of imports of coal-tar chemicals was $1,196,248 in April, a decrease of $250,000 over the imports of March, but still a slight increase over the total imported in April of 1922.

The value of paints, pigments and varnishes imported during April was $348,807. This is a slight increase over March, when $300,525 were brought into the country. Imports of these commodities, however, are measurably less than they were in April of 1922. The value of fertilizers imported in April was $7,033,299, a decrease of $800,000 as compared with March, but double the value of the imports in April of 1922. Nitrate of soda alone contributed $4,898,762 to the April total. This is nearly five times the rate of imports in April, 1922, but imports in March were valued at $5,691,097.

Some of the individual items which show marked changes in the trend of imports in April of last year are as follows:

	April, 1922	April, 1923
Creosote oil (gal.)	3,270,081	4,621,537
Naphthalene (lb.)	274,815	1,789,425
Toluene (lb.)	337	122,460
Quinine salts (oz.)	123,096	
Quinine sulphate (oz.)		185,928
White arsenic (lb.)		1,476,066
Formic acid (lb.)		144,292
Oxalic (lb.)	18	129,737
Sulphuric (lb.)		3,402,917
Nitrate of ammonia (lb.)		910,613
Arsenic sulphide (lb.)	1,348,280	207,750
Barium compounds (lb.)		974,553
Glycerine (lb.)	221,905	1,821,602
Cyanide of potash (lb.)	282,360	597,627
Carbonate of potash (lb.)	242,542	
Sodium cyanide (lb.)	2,566,195	1,445,643
Calcium cyanamide (tons)	1,441	3,906
Sulphate of ammonia (tons)	601	

The figures are those of the Department of Commerce. Due to the great amount of additional work occasioned by the passage of the new tariff bill, these figures still require more than the usual time to compile. Progress is being made, however, and the April figures were prepared on the department's work sheets less than a month later than required for the task of compilation prior to the passage of the new tariff act.

German Goods Free From Export Regulations

Exporters Must Quote in High Exchange but Accept 40 Per Cent in Paper Marks

Cable advices from Berlin recently announced that export price control, export taxes and licensing of a number of general classes of German goods had been abolished by the Federal Economic Council. Further details are now available and show that the decree became effective on May 27.

Among the articles specifically mentioned as free from the previous export regulations are: All vegetable fiber, except flax; animal fats, waxes and products; liquid resins, aromatic greases, solid tanning extracts; all hides, leather goods, excepting hairy hides; all rubber goods; fish oils, bristles, horn, antler, bone, hoof, whalebone, shells and their products; tanning bark and logs; mineral gums; mineral oils and products.

It is also added that export prices must be quoted in high exchange currency, and at least 40 per cent of the resulting credit must be surrendered to the Reichsbank, which in turn reimburses the exporter in paper marks at the current rate.

Maine Offers Paper Courses in Summer School

The chemistry department of the University of Maine will conduct a summer school course in pulp and paper chemistry and technology from June 25 to Aug. 4.

The work given is designed to meet the specific needs of students who desire and are qualified to take pulp and paper courses and also for pulp and paper mill men who may or may not have technical training, but who have had practical experience and desire to gain a scientific knowledge of important phases of pulp and paper manufacture and testing or phases of work with which they are unfamiliar.

All work completed will be given the regular university credit for either the bachelor's or master's degrees. Transference of credits to other institutions will be arranged for as during past years for those so desiring.

The courses to be offered this summer give an option of six different subjects, whereas in former years only three have been given. Three courses are offered to those interested in pulp and three to those interested in paper. Anyone wishing to take part pulp work and the rest paper may do so providing the courses do not conflict.

Supreme Court Upholds Mennen Co. Price Policy

The application of the Federal Trade Commission for a writ of certiorari in the Mennen Co. case was refused last Monday by the United States Supreme Court. This means that the decision of the Circuit Court of Appeals will not be reviewed. The original complaint against the Mennen Co. was filed April 15, 1920 and was amended Jan. 27, 1921. It alleged that the company, in addition to being guilty of the general charge of unfair methods of competition, also was operating in violation of section 5 in classifying its customers into two groups according to a basis of selection by allowing to purchasers of the same quantity and quality of its products different discount rates, according to the classification of such purchasers. On March 3, 1922, the commission entered a cease and desist order against the Mennen Co. The respondent appealed, and the United States Circuit Court of the Second District held adversely to the commission.

The decision of the Supreme Court is regarded as very important, as the case will be regarded generally as a precedent and establishes that a manufacturer may adopt price schedules that seem fair to him and may select its own customers and distinguish between wholesale and retail branches of the trade.

Larger Sales of German Potash

The German Potash Syndicate in 1922 sold 1,295,579 tons of pure potash, says the annual statement of the Deutsche Kaliwerke. This is an increased output over 1921, when 921,147 tons was produced. The 1922 sales in Alsace are estimated at 250,000 tons. About 50,000 tons K_2O was produced from all other sources.

The annual statement points out that had the normal pre-war increase continued, 1922 sales should have aggregated 2,400,000 tons, or 800,000 tons more than the 1922 sales. The 1922 sales were divided 74.4 per cent inland and 25.6 per cent export. The statement comments on the improved sales to Poland and to the United States. The "closing down law" has been extended until July 1, 1924.

The statement reveals that 181 plants contributed to the 1922 production throughout the year. In addition there was some contribution from 22 other plants.

Coal-Tar Census Completed

Final tabulations of the annual census of coal-tar products and synthetic organic chemicals have been completed by the Tariff Commission. W. N. Watson, acting chief of the chemical division, expects to send the report to the public printer about June 20. It is probable that a summary of the census, in the form of a press release, will be made public before the complete report comes from the printer.

Government Suit Against Foundation Making Little Progress

Evidence Produced Largely Regarded as Irrelevant by Court—Request for Dismissal of Suit Likely in Near Future

THE SECOND WEEK of the federal court trial of the government's suit against the Chemical Foundation has produced no startling developments. Very much of the evidence produced by Assistant Attorney-General Henry W. Anderson, who is pressing the case for the government, is regarded as irrelevant by the court. Frank L. Polk, who was Under Secretary of State during the Wilson administration and who signed the order making valid the sale of the disputed 4,800 patents to the Chemical Foundation, upset the assertion of Anderson that he was duped into the deal. As a result the case of the government is regarded as being much weakened. Dismissal will probably be asked by the defense at next week's session.

The legal point upon which the case hinges is the right of the courts "to review executive discretion." The defense argues that such a right does not exist. The court apparently holds the same view. That being the case, the arguments of the government, which are based on the assumption that the opposite view should hold, lose much of their significance. In reply to a direct question by the court as to why he signed the order Mr. Polk said:

"Because I felt here was an opportunity to build up a real chemical industry in this country, something we had never had before."

Further on, Mr. Polk said that he thought it was a wise plan to turn these patents over to the Foundation to make American industry independent. The witness added that he knew of no suppression of facts relative to the seizure of the patents. The charge made that President Wilson did not realize the significance of the act of sale of the patents to the Foundation was likewise refuted by the evidence of Mr. Polk.

Nitrate Patents Under Fire

Introducing documentary evidence Colonel Anderson endeavored to prove that the idleness of Muscle Shoals is due to the refusal of the Foundation to grant patent rights to the government, except under conditions which the government insists made it impossible to go ahead with its development plans. He contended that the program of the War Department was seriously impeded by the failure of A. Mitchell Palmer, as Alien Property Custodian, to sell the department patents it required for "offensive and defensive" purposes. In effect, it was charged that the government was "double crossed." After assuring the War Department that it would receive the patents it needed for war and peace purposes, including Muscle Shoals, Palmer sold them to the Chemical Foundation.

Isidor J. Kresel, counsel for the defense, asserted that the War Department asked only for licenses; that the Custodian had granted the Navy Department licenses on 5,700 patents that never went into the hands of the Foundation, and that the Haber patents, which the government said were necessary to the Muscle Shoals development, were not necessary to that project.

Friendly Litigation Attacked

Colonel Anderson tried to make a big point out of a proposal by Ramsey Hoguet, former patent attorney for the Alien Custodian, that the Foundation and the government engage in friendly litigation. But even here the points emphasized by the government were minimized by Judge Morris. The court has already indicated a number of times its intent to hold with the defense that war acts of a President are not reviewable by the courts. On this principal contention rests the fate of the suit in equity.

Hammermill Offers Fellowship

The Hammermill Paper Co., through its chemical director, Dr. Bjarne Johnson, has offered to the trustees of the New York State College of Forestry a fellowship for the coming year (September, 1923-24) to be known as the "Hammermill Fellowship in Pulp and Paper Manufacturing."

The fellowship requires that the recipient be a graduate student at the college (his work leading to the degree of M.S.). His major problem, which is to be chosen jointly by the Hammermill company and the department of forest chemistry, is to be of fundamental nature.

Burton L. Kassing, of Utica, N. Y., a member of the graduating class, has been designated by the company and the college as the recipient of this honor.

Germany Using Ash Fuel

With the idea of reducing fuel costs, the German chemical industries have been advised to recover combustible carbon from old ash piles. The occupation of the Ruhr has resulted in such increases in fuel costs as to make it impossible to produce certain chemical products in competition with world prices.

Under ordinary conditions, one-sixth of the carbon content of coal passes into the ash. The percentage is much higher in the coke used at smelters and gas plants. Under present conditions in Germany it is believed that many large ash dumps can be reworked at a profit. It also indicates the determined effort the Germans are making to keep their chemical industry alive.

Lime to Get Main Efforts at Non-Metals Station

Impossible to Carry On Research in Several Fields Because of Small Staff—Slate Follows Lime

The principal problems to be undertaken on the opening of the new non-metals experiment station of the Bureau of Mines at New Brunswick, N. J., will be a continuance of the study of the difficulties met with in the quarrying and preparation of limestone and in lime manufacture, and a continuance of the work which has been in progress at the Tuscaloosa station on mineral fillers.

The work necessarily will be limited, as the appropriation permits of the employment of three technical men only. Since considerable work has been done on lime and mineral fillers, it is felt that the greatest good can be accomplished by carrying through the work already well in hand.

In lime the most important portion of the work probably centers around efforts to utilize waste. There is reason to believe that improved methods of burning can be brought to the point where the smaller sizes can be burned.

It is possible that some work on slate will be taken up early in the life of the station. This is encouraged by the success which has attended large-scale pulverization of waste slate, and the increasing demand for this material as a filler in asphalt, roofing materials, paint and rubber.

The problems of the non-metals are of such a character that field work is required in much larger proportion than laboratory work. The studies and the experiments must be carried on under operating conditions. For that reason Oliver Bowles, who will be in charge of the new station, believes it is better to expend the appropriation in a way that will allow all necessary field work. Consequently he must limit the personnel of the station to a mineral technologist and a physical chemist. In case co-operative arrangements can be made with the industries concerned, it will be possible to expand the work further.

Calcium Carbide Order Revoked

The Treasury Department has revoked its order against calcium carbide from the Province of Quebec, Canada, issued May 16 under the anti-dumping act, and has instructed collectors to disregard the order and to discontinue any pending proceedings which may have been started by its authority.

It is understood that the anti-dumping order was issued as the result of suspicion by an appraiser at a border port that a consignment of calcium carbide from Quebec was invoiced at too low a price, indicating that it had been sold for export at less than its fair value. Canadian producers protested the order and at a hearing before Judge McKenzie Moss, Assistant Secretary of the Treasury in charge of customs, convinced customs officials that there was no dumping of the chemical.

Washington News

African Company Has Large Soda Deposits

A report from Consul W. L. Jenkins says that the Magadi Soda Co., at Lake Magadi, Kenya Colony, Africa, has a property covering 90 square miles, including the lake area of 34 square miles of carbonate of soda. There are very few natural deposits of soda in the world, and in this one the percentage of pure soda is as high as 96. The supply is practically inexhaustible, owing to the rapidity with which the soda re-forms. A prominent employee of the company states that only 4 square miles have been worked since operations began in 1912-13, and that by the time work was begun on the third square mile the first already had re-formed.

The Magadi company has a capital of over £2,000,000. It suffered greatly during the war, but present prospects are much brighter. It now has a capacity of 6,000 tons a month, which was expected to be increased to 12,000 in March or April of this year. The proposed increase is all the more striking since customs figures show that total exports of soda amounted to only 16 tons in 1913, 12,061 tons in 1919 and 12,829 tons in 1921. The values for these 3 years are given as £1,200, £269,258 and £107,166, respectively.

Shipments to the United States began in 1922 and tend to increase. The other principal markets are England, the Netherlands, Denmark, South America and Japan.

April Output of Acetate of Lime Shows Decline

The Department of Commerce announces the April production of acetate of lime and methanol based on reports received by the Bureau of the Census in co-operation with the National Wood Chemical Association.

The following table shows total comparative figures for the first 4 months of 1923, as reported by firms with a daily capacity of 4,500 cords, or prorated to that capacity in months where some reports were lacking, taken from the *Survey of Current Business:*

	Production		
1923	Acetate of Lime Thous. of Lb.	Methanol Gallons	Stocks of Wood End Month Cords
January	16,544	933,171	833,767
February	13,894	733,179	807,782
March	15,569	831,784	769,174
April	13,575	738,059	746,626

Argentine Tariff Revision

A report from Buenos Aires states that a proposal has been submitted to the Argentine Congress for an increase of 50 per cent on customs import valuations, and recommending also the exemption from import duties for lumber and certain other construction materials, as well as industrial machinery.

Gain in Industrial Alcohol Production

Because the production of industrial alcohol during the 9 months ended with March reached a total of 48,857,894 wine gallons, Prohibition Commissioner Haynes, in reviewing the administration of the Prohibition Unit of the office of the Commissioner of Internal Revenue, holds that "this clearly demonstrates that the administration of the alcohol laws, by this unit, has interfered in no way with normal commercial processes." He points out that trade alcohol production in those 9 months was greater than during the 12 months of the fiscal year beginning July 1, 1920.

"The number of plants now qualified to produce alcohol," says the Prohibition Commissioner's report, "is practically the same as 2 years ago, or about seventy in number, but at present they are working at a greater capacity than they were then."

The report gives the following figures covering withdrawals of specially denatured alcohol: During the 12 months ended with February, 1923, 25,505,940 gal.; during the corresponding period ending February, 1922, 12,719,452 gal.; during the corresponding period ended with February, 1921, 11,767,587 gal. The figures for completely denatured alcohol follow: During 12 months ended with February, 1923, 22,766,389 gal.; during the corresponding period ended with February, 1922, 15,483,003 gal.; during the corresponding period ended with February, 1921, 13,319,230 gal.

Standards Augments Staff

The Bureau of Standards has just appointed two additional chemists to be members of its sugar laboratory research staff. Dr. C. S. Hudson, who has done a great deal of work on rare sugars and organic chemical research in connection with these substances, will join the bureau organization shortly to continue his researches in this field. The Corn Products Refining Co. has appointed Dr. H. Berlin as a research associate in this same organization. He will be engaged on physical chemical research in connection with starch and its hydrocarbon derivatives. The work of this section of the bureau is directed by Dr. F. J. Bates.

Appraisers Sustain Protest on Soap

Perfumed toilet soap, assessed at 40c. per lb. and 60 per cent ad valorem under paragraph 48 of the tariff act of 1913, should have been assessed at the rate of but 30 per cent ad valorem under paragraph 66, according to an opinion just handed down by the Board of United States General Appraisers, sustaining a protest of Park & Tilford.

Rarer Chemicals Require Greater Protection

Applications for increases in duty on amino acids and rare sugars have been filed with the Tariff Commission by the Special Chemicals Co., Highland Park, Ill. No action has been taken by the commission.

Amino acids are included in the basket clause of paragraph 5 of the tariff act of 1922 at 25 per cent ad valorem. They are used to supply missing elements in certain foodstuffs and as medicinals. Rare sugars are in paragraph 504 of the tariff act at 60 per cent ad valorem. They are used principally in laboratory bacteriological tests.

While the total volume of each consumed in the United States is small, due to their uses, they are said to be highly important to medical science and the development of a domestic producing industry is viewed as of importance by military medical officers.

Germany is the principal competitor in the production of these acids and sugars. In the case of both, the protection given by the 1922 tariff act is described by the applicant as ineffectual. German rare sugars, for instance, are laid down in this country $25 per pound cheaper than the cost of production in the United States. The application asks that the duties be transferred from foreign valuation to American valuation, which would leave the figures in the act the same but would increase the duties several hundred per cent.

German Plant to Produce Synthetic Urea

A report from D. S. Haven, consul at Leipzig, states that during the war the Germans erected near Merseburg, in the Province of Saxony, the great chemical plant known as the Leuna Works. This establishment covers an area of approximately 1½ square miles and employs 18,500 men. It was designed for the purpose of extracting nitrogen from the air. This product was intended exclusively for agricultural purposes. Present plans are to devote a large portion of the plant to the manufacture of synthetic urea by the Haber and Bosch processes. It is probable that the urea will be converted into the nitrate of urea containing 46.6 per cent of available nitrogen, which the Germans claim will be the principal source of nitrogen in the fertilizers of the future.

Resin Found in Mexico

A report from Mexico City announces the discovery of a new resin in Mexico. This resin is said to be suitable for commercial purposes and is taken from a tree known by the name of "Cuapinole," found in the tropical zone of Mexico. When analyzed the resin was found to be of such quality that it can be used in the manufacture of the finest varnishes. One of the features of this new resin is that it is not soluble in either alcohol or gasoline.

Trade Notes

The J. A. & W. Bird Co., Boston, Mass., has been formed under state laws with a capital of $200,000, to succeed to and expand the plant and business of the company of the same name, with offices at 88 Pearl St. The company specializes in the manufacture of glue, floor oils, etc., and the new charter provides for the production of chemicals, paper products, etc. Reginald W. Bird is president; John B. A. Regnier, vice-president; and Adrien E. Regnier, treasurer.

A receiver has been appointed for the Joslin Schmidt Co., Cincinnati, O., manufacturer of chemicals and fertilizer, on application of the American Oak Leather Co. Liabilities are stated as approximately $400,000, and assets $1,290,000 "depreciated valuation."

The American Can Co. will build two large additions to its plant at San Francisco. The improvements will include a manufacturing and storage building as well as an office building.

H. A. Forbes, 81 Fulton St., New York, has been designated as agent of the recently formed Potash Importing Co. of America, which is a Delaware corporation.

A special meeting of the Paint, Oil and Varnish Club of New York has been called for June 26. The meeting will be held during and in connection with the annual outing of the club and will be held for the purpose of considering applications for membership.

George S. Whitty, chemist for 28 years at the Brooklyn plant of Devoe & Raynolds Co., Inc., resigned on June 1 to take charge of production for the Amalgamated Paint Co., Jersey City, N. J.

The erection of a refinery and the mining of asphalt at Flint, Ala., is contemplated in the near future by the Southern Rock Asphalt Co., according to an announcement made by L. D. Powell, Alabama manager of this concern. At present Mr. Powell is directing a series of "core-drilling" tests near Flint and stated that several samples of the Alabama asphalt had been analyzed and found to be even richer than the Kentucky deposits owned by the same company.

Henry H. Stiller, formerly with the Superfos Co., is now associated with the Wishnick-Tumpeer Chemical Co., in the capacity of manager of the New York office which has been opened at 130 West 42d St.

The Scientific Chemical Co., 141 West 36th St., New York, has been petitioned into bankruptcy. Susan Brandeis has been appointed receiver.

During April Singapore exported 4,500 long tons of refined tin, of which the United States took 68 per cent.

Germany's Zinc Dust Industry Explained by Commissioner Grey

Uses of This Commodity, Imports, Exports, Producing Firms and Interesting Sidelights in His Report

AN INVESTIGATION made with the co-operation of chemical engineers, brokers in chemical products and consumers of zinc dust, as well as with the aid of technical periodicals and handbooks, has yielded information with regard to zinc dust which is of considerable value to the industry in this country.

This product is extensively manufactured in the United States, Great Britain, Germany, Belgium, Holland and Australia. The commercial product is generally impure and contaminated with lead, iron and cadmium, as well as with zinc oxide. The so-called pure product is made by a very limited number of firms in Germany and contains a varying percentage of zinc oxide. The price is adjusted according to the oxide content.

Recent official import and export statistics are available only for the period covered from 1910 to 1912, inclusive, and 1920 to the beginning of 1923.

Germany's chief source of supply before the war was Belgium. The quantities imported from all sources gradually diminished to 650 tons in 1912. The figures rose to 1,238 tons in 1922, with Belgium being the origin of 459 tons and Polish Upper Silesia 667 tons. Before the Versailles treaty what is now Polish Upper Silesia was part of Germany, and products originating there were not considered imports. At the present moment more than 50 per cent of the imports are from that source.

The imports as officially published appear below:

Country of Origin	1910	1911	1912
Belgium	920 4	687 3	514 6
Austria-Hungary	226 1	79 9	119 7
Polish Upper Silesia	.	.	. .
Other countries	.		.
Total metric tons	1284 6	787 9	650 6
Value million marks	0 578	0 378	0 338

Country of Origin	1920	1921	1922
Belgium	.	. .	458 9
Austria-Hungary			
Polish Upper Silesia	.		666 6
Other countries		.	112 5
Total metric tons	65.1	30 8	1238 0
Value million marks	.	0 123	323 0

U. S. Formerly Heavy Buyer

Before the war the United States was Germany's heaviest buyer of zinc dust, but as the home production in America rose from 69 tons in 1910 to 11,339 tons in 1920, the exports to the United States dwindled to 1,030 tons in 1912, with no figures given thereafter. A resumption of statistics occurs in 1920, but for that year and for 1921 the exports of zinc dust are merged with those of zinc oxide (Zinkgrau and Zinkasche). There is no special grouping of the United States as an export outlet after 1912, the only practical inference being that it is included in the group of "other countries."

In 1922 Germany exported only 603 tons, which is less than 14 per cent of the 1912 record. Deducting this quantity from her total imports of 1,238 tons during the same year leaves 635 tons for her home consumption, a figure significantly close to the 666 tons which Germany imported that year from Polish Upper Silesia, part of her former empire.

It is interesting to follow the suggestion of the loss to Germany of the resources of this commodity as represented in the separation of Polish Upper Silesia. In 1910 Germany exported 1,806 tons more of zinc dust than she imported. The source of this overplus was unmistakably what is now Polish Upper Silesia and the Aix-la Chappelle region, occupied by the Belgians under the Versailles treaty. The suggestion is strengthened by the figures for 1911, when the exports overbalanced the imports by 3,161 tons and in 1912, when the same item was 3,696 tons. The situation may be studied with more exactness by consulting the export table below:

Country of Destination	1910	1911	1912
Belgium	203 3	154 5	535 4
Denmark	30 4	103 6	83 4
Great Britain	660 2	609 8	833 4
Netherlands	150 6	171 8	700 8
Austria-Hungary	246 3	325 8	327 4

China			48 5
Mexico			.
U. S. A	.		. . .
Japan			63 4
Sweden	694 4	80 1	. . .
Other countries	969 4	921 5	283 9
Total metric tons	4261 2	2820 1	603 5
Value in thousands of marks	19,254	15,988	100,717

(a) The totals of German exports are not always the aggregates of the component items, but should be preferred to any true sum of the detailed items. Exporters make their entries in the export declarations and these are relied upon in making up the individual items. However, the totals recorded at the end of the year represented the exact aggregate shipped out of the country.

(b) The figures for 1920 and 1921 include both zinc dust and zinc oxide.

Among the manufacturers in Germany producing pure material there are the following: Kahlbaum, Adlershof-Berlin; Merck, Darmstadt; Schuckert, Gorlitz; Hohenlohenhuette, Upper Silesia; Gische's Erben, Breslau.

In England the main manufacturers are: H. S. Willcocks & Co., Manchester; Keeling's Oxides (est. 1921), Ltd., 35 Surrey St., London, W. C.; May & Baker, Battersea, London; Prescott & Co., Rutland Mills, Hulme, Manchester.

News Notes

Harvard University is to have a new chemical laboratory. A gift of half a million dollars from Edward Mallinckrodt, Sr., of St. Louis, is to be used for the new building. Three such buildings are regarded as necessary to provide ample laboratory facilities at the university.

Henry Ford has recently acquired the right to utilize the High Dam on the Mississippi for a period of 50 years. It is understood that Mr. Ford is planning to manufacture storage batteries for his cars at his St. Paul plant, which is near the dam. The estimated output of the plant is 6,000 batteries per day.

The Swedish glass industry, which has suffered much through foreign competition, is now recovering and activity is being resumed at most works. Both window and plate glass plants are affected. A few of the smaller establishments which rose during the war have not opened up and, according to a Reuter dispatch, probably never will.

Formulation of standards, specifications and tests for purchases of materials is being sought by the Department of Commerce at the request of state agents and representatives of private institutions. Meeting in Washington on June 11, delegates from all interested technical and business associations along with agents from 26 states conferred with Secretary Hoover with regard to the matter.

Natural gas can flow across state lines whether or not the government of the state which contains its source decrees that it may. A decision to this effect was arrived at in a verdict rendered by the Supreme Court on June 11. Ohio and Pennsylvania thereby lost a case presented against the state of West Virginia.

The soft drink industry is the United States is assuming tremendous proportions. Approximately 4,000,000,000 bottles of beverages so classed are being consumed annually. This industry is creating a large market for carbon dioxide, tartaric, citric or phosphoric acid and artificial fruit sirups.

Germany's unmined potash resources contain two billion tons of K_2O, an estimate recently published by the German Foreign Office states. This is apart from about 300,000,000 tons of K_2O in the unmined Alsatian deposits.

The oxygen enrichment committee, of which M. H. Roberts is chairman, met in the office of Dorsey A. Lyon, assistant director of the Bureau of Mines, on June 9. The committee spent the day reviewing the report submitted by F. W. Davis. The report deals with the use of oxygen or oxygenated air in metallurgical and allied processes. Before publication, the report will be submitted to the industry for criticism or suggestion.

All necessary funds have been secured for the construction of a ceramics building at the Georgia School of Technology, Atlanta, and work will be placed in progress at an early date. The structure will be the first institution of its kind in the South.

The Franklin Institute, Philadelphia, Pa., has commenced the remodeling of four old structures at 19th and Race Sts., to provide a new research laboratory department at the institution. The work will be carried out under the direction of the Henry W. Bartol Research Foundation of the Institute, and complete equipment will be installed for general research in the field of physical science. A total of twenty individual laboratories will be provided for experimental research. It is expected to have the extensions ready for use when the institute celebrates its one hundredth anniversary early in the fall.

Plans for 1923 Exposition Taking Shape Rapidly

The 1923 chemical industries exposition may be turned into a huge "buying fair" if plans discussed by the advisory committee on June 6 develop. The central idea of the scheme is to have each exhibitor display his goods in a novel manner so worked out that it will demonstrate their particular characteristics, special uses and selling points. Full sales forces of those having exhibits would be present, according to the plan, in order to attend joint as well as company conferences. Contacts resulting from such conferences were pointed out to be very desirable.

Major H. S. Kimberly, who has charge of the educational exhibits this year, provided a tentative report at the meeting. The chief object of the exhibits will be to demonstrate to the business man what chemicals can do and are doing, and, so far as possible, the place of chemistry in business. Kitchen and food chemistry are not to be neglected. Both the Chemical Warfare Service and the Bureau of Chemistry are planning exhibits for educational purposes. The actual educational work, which is to be carried in the form of a practical course in chemistry and chemical engineering, is to be in charge of Dr. W. T. Read of Yale University. Authorities in various branches of the science are to give the lectures which will cover the entire week of the exhibition.

Announcement was made at the meeting on June 6 that there will be a joint meeting of the advisory committee with all exhibitors on June 28. Those present at the last meeting included Dr. Charles H. Herty, chairman; Raymond F. Bacon, John W. Boyer, Henry Howard, Percy C. Kingsbury, T. C. Oliver, R. P. Perry, Charles F. Roth, H. J. Schnell, C. Wadsworth, T. B. Wagner, R. Gordon Walker and Milton C. Whitaker.

Southern California A.C.S. Elects Officers

At the May meeting of the Southern California Section of the American Chemical Society, held at Los Angeles on May 24, the following officers were elected for the ensuing year: President, Walter A. Schmidt; vice-president, Dr. W. C. Morgan; secretary, Mark Walker; treasurer, C. J. Martin; councilors, Dr. S. J. Bates, H. L. Payne and E. R. Miller. Mr. Payne was elected chairman for a second term. The secretary reported that the average attendance at the dinners held during the past season was 103, and the average attendance at the lectures was 144.

After the business meeting the following papers were read and discussed: Dr. I. Grageroff, "Fundamental Problems in Biological Chemistry"; Dr. H. L. White, "Chemical Nature of Some Physiological Products"; Dr. M. C. Terry, "Relation of Chemistry to Medicine From the Standpoint of the Bacteriologist."

Explosion Study at Carnegie

A study of the factors causing mine explosions will be undertaken at Carnegie Institute of Technology, according to an announcement outlining a program of research on coal-mine problems. The study of mine explosion causes will be divided into investigations of (*a*) modification of Stokes law for settling of coal dust particles; (*b*) time-pressure relations in dust explosions; (*c*) conductivity and specific heat of coal; (*d*) static charges in coal mines; and (*e*) effect of electric field in propagation of explosions.

Six college graduates will be appointed to research fellowships to conduct the investigations in co-operation with the U. S. Bureau of Mines and an advisory board of Pittsburgh coal operators and mining engineers.

Steel Treaters Nominate

The following officers have been nominated for the American Society for Steel Treating for the coming year and nomination is substantially equivalent to election, as only a single candidate has been formally proposed for each office: For president, George K. Burgess, director, Bureau of Standards; for second vice-president, R. M. Bird, engineer of tests, Bethlehem Steel Co.; for treasurer, Zay Jeffries, metallurgist, Aluminum Co. of America; for member of board of directors, J. Fletcher Harper, research engineer, Allis-Chalmers Manufacturing Co.

New Calcium Arsenate Producer

The Salt Lake Insecticide Co., of Salt Lake City, Utah, is now producing calcium arsenate, and shipments of carload lots are being made to the cotton states of the South. The distribution of the company's product has been placed in the hands of Howard W. Ambruster, 261 Broadway, New York, as exclusive sales agent.

Facts and Figures That Influence Trade in Chemical Products

Market Conditions

Current Prices Imports and Exports The Trend of Business

Improved Inquiry for Chemicals Early in Week but Interest Not Sustained

Domestic Products Fairly Steady in Price With Foreign Offerings Feeling Effects of Forced Liquidation

DIFFERENT sellers reported an improved inquiry for chemicals in the first half of the week, but later on buying interest lagged and the market closed in a quiet condition. Some of the large consuming trades are going on summer schedule and reports from the tanning and textile industries especially indicate a slowing up in operations. This has the effect of retarding inquiries for forward deliveries and makes trading for prompt and nearby positions more important.

The weighted index shows a fractional decline for the week but this was due to weakness in imported materials and a lower selling price for linseed oil. Important domestic chemicals were practically unchanged in price during the period and large amounts are passing against old contracts. Prussiates of foreign make have maintained a downward course and new lows were reached for both the soda and potash varieties. Imported copper sulphate was very weak at the close of the previous week and this weakness was carried into the current period but distressed lots were gradually absorbed and prices reacted from the low level. Domestic copper sulphate has sold freely despite the competition from imported.

Export demand for chemicals has been very moderate, and caustic soda has been forced to meet with competition which forced sellers either to lower prices or to remain out of competition. Some export inquiry is heard for bichromate of soda, but nothing like the volume noted earlier in the year.

Arsenic and calcium arsenate hold a position of prime interest, but the week was devoid of new developments and outside of a general expectancy that demand will suddenly improve, there is little to note. Prices are easy, but most holders are waiting to see if stocks on hand will be needed and are slow to force matters. It is admitted by many that prices will show a decided trend one way or the other within the next two weeks.

Acids

Acetic Acid — Several consuming trades are reported to be buying in fair volume and stocks have been well absorbed. New outlets are said to have been developed especially for the lower grades. Prices are on a steady basis with quotations at \$3.38@\$3.63 for 28 per cent; \$5.48@\$5.75 for 30 per cent; \$12@\$12.75 for glacial.

Boric Acid—Sellers say that prices already are so close to production costs that further declines are improbable. Demand has been good and evidently buyers have been impressed by the low level of prices. Export business also has been stimulated while imports of crude material are a factor in increasing selling competition. Prices for powdered and crystals are 10@10½c. per lb., in sacks, with kegs at 11@11½c. per lb.

Citric Acid — Weather conditions again have not favored active buying but in some quarters better interest has been reported. Spot material is meeting with some price cutting as a few holders are eager to move stocks. The open figure for spot offerings is 52c. per lb., but sales have been made under that level. Domestic grades are held at 49@50c. per lb., but stocks of domestic are well sold ahead.

> **Prussiates Reach Lower Price Levels—Imported Copper Sulphate Firmer—Caustic Soda for Export Lower—Permanganate of Potash Very Weak—Arsenic Waiting for Improved Demand—Imported Tartaric Acid Easy—Resale Lots Weaken Nitrate of Soda.**

Hydrofluoric Acid—There is no activity in the present market but sellers say this is a seasonable condition. Prices are easier but this fails to arouse consuming interest. Quotations are 6@7c. per lb. for 30 per cent; 10@11c. per lb. for 48 per cent; 13@14c. per lb. for 60 per cent.

Oxalic Acid—The importance of imported grades is seen from the fact that in April last year only 18 lb. came into this country whereas in April this year there were imports of 129,737 lb. Chief interest still centers in imported offerings with prices varying from 13c. to 13½c. per lb. according to seller. Domestic acid is held at 13½c. per lb. at works.

Sulphuric Acid—As confirmation of the sold up condition of domestic producers in recent months it is noted that in April imports of sulphuric acid amounted to 3,402,917 lb. as compared with nil in April 1922. Buying is not as heavy as formerly but movement to consumers is large enough to hold stocks at low levels. Prices are steady at \$9.50@\$12 per ton for 60 deg. and \$15@\$16 per ton for 66 deg. in tanks. Oleum is in limited supply and \$19@\$20 per ton is quoted for tanks, f.o.b. works.

Tartaric Acid—The position of domestic has undergone no change and the open market price is held at 37½c. per lb. Imported has been on the market in larger volume and prices have weakened under selling pressure. Sales are said to have been closed at 35½c. per lb. on spot and it was stated that this figure could still be done.

Potash

Bichromate of Potash—Reports from the large consuming trades indicate lessened activity and this is reflected in the market for bichromate. In some quarters prices are quoted as firm at 11½c. per lb. and upward according to quantity but there is not much trouble in locating stocks at 11¼c. per lb. and the latter is regarded as an actual trading basis.

Caustic Potash—While some sellers say that 7½c. per lb. could have been done throughout the week, others were inclined to hold above that level and 7¾c. per lb. is quoted in different directions. Shipment prices also are given at 7¾c. per lb. but buying is not in evidence and this is regarded as a bar to any sustained firmness in price. Domestic caustic is maintained at 9c. per lb., works.

Carbonate of Potash—Stocks have been reduced by recent transactions but inquiry is dull and it still is a buyers' market. Large lots are not moving but scattered trading is reported for smaller amounts with 80-85 per cent quoted at 6½@6¾c. per lb. Hydrated 80-85 per cent is steady at 7¼@7¾c. per lb. On offerings of 90-95 per cent 6¾c. per lb. can be done and on 96-98 per cent 7@7¼c. per lb. is asked.

Cyanide of Potash—There has been very little call for this material in recent weeks and business has been confined to jobbing lots. Prices are irregular with a range according to seller, the inside price being 47c. per lb. and up to 50c. per lb. is asked.

Permanganate of Potash—The position of permanganate is shown by the fact that sales were made last week

at 17c. per lb. whereas 19c. per lb. is quoted by many holders of stocks. Irregularity in price has been a feature for some time and there is no indication that the market is approaching a more stable position. As a matter of fact distressed lots were said to have changed hands last week at 16c. per lb. which emphasizes the difference in views of sellers. Some of the material held on spot is said to have originally cost from 18½c. to 21½c. per lb. to import.

Prussiate of Potash—Yellow prussiate was one of the weak selections on the market. Buyers have been holding off and sellers have pressed matters with the result that values weakened and spot material was offered as low as 31c. per lb. The price ranged from this level up to 35c. per lb. but the latter figure was purely nominal.

Sodas

Bichromate of Soda—In spite of reports of differences in price according to seller, competition is keen enough to hold values on an even basis and 8½c. per lb. is regarded as a general price for carlots at works. Demand is not heavy but sellers say large amounts have passed on contracts and new business has been satisfactory. High cost of production is still heard as a steadying factor on prices and as surplus stocks are unusually light the market seems to be in a healthy condition.

Bisulphite of Soda—A quiet week was reported for both powdered and liquid. Consumers are buying only for current needs and this confines transactions to jobbing quantities. Prices are given at $1.40@$1.50 per 100 lb. for liquid and $4.25@$4.50 per 100 lb. for powdered.

Caustic Soda—Export business has fallen off to such an extent that it is difficult to quote a definite figure as representing the market. On outside brands $3.18¾ per lb. was heard but no business was reported at that price and with actual business in sight it is possible that lower prices could be worked. Open quotations were placed at 3.20c.@ 3.25c. per lb., f.a.s. On standard brands 3.35c. per lb. is still held as an open asking price but it is admitted that business is impossible at that level and it would require definite bids to determine just how much the quotation will be lowered on actual business. The domestic branch of the trade is fairly good with 2½c. per lb. asked for carlots, f.o.b. works. Spot material also is holding unchanged at 3½c. per lb. and upward according to quantity.

Cyanide of Soda—A lot of 25 tons now afloat was offered at 21c. per lb. Low priced lots on spot appear to have been cleaned up and 22c.@23c. per lb. was asked for spot material. For nearby shipment from abroad it was possible to do 20c. per lb. but this was qualified by the statement that this price was subject to cable confirmation.

Nitrate of Soda—The market is suffering because of fairly heavy offerings and little disposition on the part of buyers to operate. Resale lots are making the market price and spot goods can be secured at $2.45 per 100 lb. In Southern markets supplies are heavier than in the North and $2.40 per 100 lb. is given as the trading basis. There has been no change in the schedule price for future shipments from Chile but interest is not keen at present in forward positions. Refined nitrate is quiet with prices at 4¼@4½c. per lb. for granulated and 5¼@5½c. per lb. for powdered.

Nitrite of Soda—Imported nitrite held a weak position and the recent reduction to 7¾c. per lb. for spot goods still held good with the market barely steady at that figure. Domestic goods also were said to be available at the 7¾c. level but 8c. per lb. was generally held as the asking price.

Prussiate of Soda—Sentiment was bearish and prices moved accordingly. The trend of value has been steadily downward and it appears as though a market is sought for imported irrespective of price. Prices for spot material were as low as 14¾c. per lb. and the lowering of prices failed to bring out any appreciable gain in buying. For shipment over the last half of the year, there were sellers at 14½c. per lb. but this price also failed to attract orders.

Miscellaneous Chemicals

Arsenic—Feeling that demand will improve appears to have gained ground but there was no marked improvement last week and prices remain irregular. Domestic producers quote prompt shipment at 13½c. per lb., but this has no bearing on the spot market as the domestic output is passing direct to consumers. In the spot market, however, it was possible to find sellers at 13½c. per lb., and from that level up to 14½c. per lb. is asked. On shipments over the last half of the year domestic producers quote 11c. per lb. Japanese grades are offered at 11½@11¾c. per lb. and European makes at 10½c. per lb. Import figures show that 1,476,066 lb. of arsenic came in during April as compared with none in April last year.

Calcium Arsenate—The market is in a waiting position. So far demand has not materially improved. Unsold stocks are large and it is a question whether buying or selling will set in first. Prices are quoted around 16c. per lb., but on firm business this might be shaded.

Copper Sulphate—Distressed imported material has been disposed of and the market presented a slightly firmer appearance on spot goods. Early in the week some business went through at 4½c. per lb., but later bids at this figure were turned down. Asking prices on foreign goods on spot settled at 4⅞@5c. per lb. Imported sulphate for shipment was nominal at 4¾c. per lb. Domestic producers reported the market as unchanged. Large crystals settled at 5.75c. per lb., with the small crystals at 5.65c. per lb., carload basis.

Pyridine—Cables from abroad were higher and with little on spot prices at the close were strong. Importers refused to quote less than $4 per gal., in drums, forward delivery.

Metal Salts—The market for tin was easier, but not so as to bring out a lower trading level in tin oxide. Leading factors held out for 48c. per lb. Tin crystals were unchanged at 34½c. per lb. Nickel sales were inactive, but with no change in the metal situation prices were repeated on the basis of 11½c. for the single. Imported copper oxide was steady at 20@21c. per lb., with inquiry fair.

Barium Chloride Offerings in some directions were freer and this brought out an easier feeling in the market. However, prices are considered low and no real pressure developed. On carload business it was possible to do $80 per ton, prompt shipment. On less than carload lots $83 represented the market.

Sal Ammoniac There was some question about quality on some of the goods offered during the past week or so, and several traders were not disposed to follow in marking prices downward. Imported material did sell as low as 6c. on the recent break, but at the close last week operators were asking from 6¼@6¾c. per lb. on standard goods.

Alcohol

Several small shipments of denatured alcohol arrived here from the West Indies. The market was a steady affair so far as the domestic producers were concerned, demand being satisfactory, especially in the special grades. Formula No. 1, special, held at 35c. per gal., in drums, and 41c. per gal., in barrels. The completely denatured, formula No. 1, was offered by leading interests at 43c. per gal., in drums. Ethyl spirits, U.S.P., 190 proof, was nominally unchanged at $4.70 per gal., in barrels. Butyl alcohol, in drums, f.o.b. works, held at 26@27c. per gal. Production of methanol in April amounted to 738,059 gal., which compares with 831,784 gal. in March. The market was unchanged but steady at $1.18@$1.20 per gal., the price depending upon the grade.

Higher Prices for Potash

A Reuter's despatch from Berlin states that the Reich Potash Council has decided to increase the prices of potash by 45.72 per cent as from June 1.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	177.88
Last week	178.17
June, 1918	272.00
June, 1919	229.00
June 1920	274.00

June, 1922	157.00

An easier feeling prevailed and the decline in spot linseed oil was a factor in lowering the index number 29 points.

Coal-Tar Products

Phenol on Spot Offered Down to 42c.—Naphthalene Unsettled—Benzene Moving Slowly—Salicylates Quiet

PRODUCERS reported no price revisions, but second-hands offered spot material in a more liberal way and in order to move goods were disposed to meet the views of prospective buyers. The volume of business placed last week was disappointing. In the case of phenol the talk of increased production has restricted buying to a minimum. Actual offerings were not large, either for prompt or nearby shipment, but lack of buying interest again forced prices to lower levels and resale parcels could have been picked up at 42c. per lb. Leading producers, on the other hand, were not anxious sellers of nearby material. Cresylic acid was available on spot at slight concessions. The benzene situation was not considered favorable from the producers' standpoint, due chiefly to the low position of gasoline, but first-hands saw no reason for forcing sales, believing that the motor fuel market should improve from now on. Inquiry was reported for pure xylol. A small shipment of this commodity arrived here last week from abroad. Naphthalene demand showed moderate improvement, but offerings were plentiful and prices continued rather easy. Salicylates were unchanged.

Alpha-Naphthol—Prices named covered a wide range, depending upon the make. But actual trading was along routine lines and some selling pressure in outside channels unsettled the market. On the crude prices ranged from 60@70c. per lb.

Aniline Oil—Offerings were freer, but leading interests continued to quote on the basis of 16c. per lb., prompt shipment from works. On forward business it was possible to do slightly better, where round-lots were concerned.

Aniline Salt—Most traders held out for 23c. per lb., prompt shipment. This price was not firm, and scattered lots were available at concessions.

Benzoic Acid—A moderate inquiry was in evidence for the U.S.P. grade and prices steadied. For spot material asking price ranged from 77@80c. per lb. On forward business 72c. was the nominal quotation. The technical held at 70c. per lb. Offerings were light.

Benzaldehyde — Leading producers continued to quote the market steady at 75c. per lb. The stocks on hand were considered light, which offset temporary quietness in trading. The customary premium obtained on the U.S.P. grade.

Benzene—Offerings of the 90 per cent grade were plentiful, and with business anything but brisk, prices in some quarters presented an easier feeling. Leading interests, however, continued to quote on the basis of 25c. per gal., tanks, f.o.b works. The pure, in tanks, for prompt shipment, closed at 27c. per gal.

Cresylic Acid—Several small shipments arrived from English ports. There was no buying interest in the imported material for shipment from the other side. Scattered lots of spot goods could have been picked up below the prevailing cost of import. The 97 per cent sold down to $1.10 per gal. In general traders held out for $1.15. The lower grade was nominal at $1.05@$1.10 per gal.

Naphthalene—Moderate improvement was reported in flakes for immediate delivery, but with offerings fairly large, the market failed to steady. In fact it was possible to pick up scattered lots at concessions. During the week business went through at 8@8½c. per lb. The market for the crude was neglected and on English material for shipment offerings at 3@3½c. per lb., c.i.f., attracted little or no attention. On continental crude there were sellers around 2¾c. per lb., c.i.f. basis.

Paranitraniline — While the market settled at 70@75c. asked, as to make, scattered lots of spot goods did sell down to 68c. per lb. The demand was slow all week.

Phenol—The market was inactive and prices for spot material in outside channels were considered little more than nominal. Some traders continued to quote around 50c. per lb. on the U.S.P. grade, but admitted that better could have been done in other directions. Several parcels of resale material were around at 42c. per lb., a new low for the movement. Buyers were disposed to operate in a hand-to-mouth way only, believing that enough new production will come out by this fall to put the market on a fairly normal trading basis. Leading interests would not name a flat price on nearby material, but intimated that business might be acceptable around 30c. per lb.

Salicylic Acid—The demand was inactive, but no further price revisions were named by producers. Quotations settled nominally at 40@45c. per lb. on the U.S.P. grade.

Solvent Naphtha—A firm undertone featured the market as the supply was inadequate and producers could not see their way clear to bring out larger supplies in view of the peculiar marketing conditions in coal-tar crudes. The water-white held around 27@32c. per gal., tank car basis, f.o.b. works.

Xylene—Some buying interest was reported in the pure material, but with offerings scanty, the market for spot goods was wholly nominal, ranging from 95c.@$1 per gal. On contract 75c. could have been done.

Financial Notes

Merck & Co. have declared a dividend of $2 per share on the preferred stock of the company, payable July 2 to holders of record June 16. This is the first dividend on the issue since July 1, 1921.

The Tennessee Copper & Chemical Corp. has declared a regular quarterly dividend of $25 a share, payable July 16 to stock of record June 30.

The Dominion Textile Co., Ltd., of Montreal, has declared the regular quarterly dividend of 1¾ per cent on preferred stock and $1 per share on common stock. Three months ago a dividend of 3 per cent was declared on the common stock.

The Vulcan Detinning Co. reports for the quarter ended March 31 last net profit of $67,705, after charges and taxes, against $21,442 in the first quarter of last year. Sales amounted to $544,143, against $308,460, and expenses $435,226, against $291,433.

Vegetable Oils and Fats

New Crop Cottonseed at 7c. f.o.b. Mills—Spot Linseed Lower—Palm Oils Decline—Soya Easier on Coast

PURCHASING AGENTS took the stand that the outlook favored buyers and with new crop developments in cotton and flaxseed gaining in importance as market factors operations during the week were held down to a minimum. Some speculative transactions in new crop cottonseed oil took place, but these did not assume large proportions and most traders were inclined to fight shy of this class of business. Spot linseed was easier on reports that several crushers have caught up on deliveries.

Cottonseed Oil—Trading in cottonseed oil options on the Produce Exchange was inactive. Early last week the July option firmed up on covering by shorts, but as soon as this demand was satisfied prices eased off. In futures the undertone was rather easy because of the uncertainty surrounding the new crop. The season is 2 weeks late throughout the South and reports on the new crop were not exactly encouraging. Private preliminary estimates on cotton production range all the way from 11,000,000 to 12,000,000 bales, a rather wide difference of opinion. Business in refined oil was moderate only, but with a tight statistical situation on old crop oil bears were inclined to go slow. Live hogs were unsettled on liberal receipts and Chicago reported the market at \$6.85@\$7.05 per 100 lb. Cash lard in Chicago held around 11.20c. per lb. In the opinion of some traders cheap hogs and lard tend to offset the bullish statistics on cottonseed oil. Trading in old crop crude cottonseed oil was limited because of the scanty supply and the market settled at 10c. per lb., buyers' tanks, f.o.b. mills. Transactions in new crop crude of a speculative character were few and far between, but some business did go through at 7c. per lb., f.o.b. Texas points, November-December-January shipment. New crop October oil was offered at 8¼@8½c. per lb., f.o.b. mills, Texas. Bleachable for prompt shipment from the South was nominally unchanged at 10½c. per lb., buyers' tanks, f.o.b. mills. Lard compound in New York held at 13@13½c. per lb., carload basis.

Linseed Oil—Several crushers were in a position to quote on prompt carload business and this resulted in lower prices for nearby oil. On futures, however, the market appeared to be a little firmer as crushers were not disposed to force the market until a better survey of the world's seed situation is possible. The crop outlook in the Northwest is regarded as favorable and according to reports received here late last week seeding in North Dakota is still in progress. One operator went so far as to predict that the acreage figures, when available, will make the best showing in several years. Where the new crop is above ground the condition is said to be good. Argentine shipments continue at a liberal rate, but covering last week by July shorts revealed that the supplies must be in pretty firm hands. Indian offerings are being absorbed by the United Kingdom. Demand for linseed oil during the week was moderate only. Distressed foreign oil on spot was purchased by a crusher and this steadied the imported commodity. Domestic oil sold for prompt shipment at \$1.10 per gal., cooperage basis. July was offered at \$1.06 per gal., with August forward at \$1.03 per gal. Linseed cake for export was quiet, but quotably unchanged at \$34 per ton.

China Wood Oil—The market was quiet and prices at the close were barely steady. July shipment oil was offered at 26c. per lb., in bbl., carload lots, with futures available at 22@23c. per lb. There was no buying interest in futures.

Coconut Oil—One tank car of Ceylon type oil sold for prompt shipment at 8½c. per lb. On the coast the market held at 8@8¼c. per lb. for Ceylon type oil, sellers' tanks, prompt and forward shipment. Demand was dull. Copra was nominally unchanged at 4⅝c. asked, Manila sun dried, c.i.f. coast ports.

Olive Oil Foots—Several parcels were pressing on the market all week and this imparted an easy feeling and held prices down. There were sellers of prime green foots on spot at 8c. per lb. On futures the market settled at 8⅜@8½c. per lb., c.i.f. New York.

Palm Oils—Importations were heavy, but most of the oil went directly to soapers. New business was inactive, due in part to the low position of tallow. Resale material on spot sold at 7c. on the Lagos grade, and at 6⅝c. on Niger. Lagos for shipment was nominal at 7½c. per lb., while Niger for forward delivery settled at 6¾@7c. per lb.

Sesame Oil—There was a little trading in spot at 11⅞@12c. per lb. Refined oil for shipment was offered down to 11c. per lb., c.i.f. New York.

Soya Bean Oil—There were sellers of crude for future shipment from the Pacific coast at 9⅝c. per lb., sellers' tanks, duty paid. One car of spot oil sold at 10c. per lb., f.o.b. New York. Several large shipments are about due here, which tends to unsettle the market.

Fish Oils—Crude menhaden oil was quiet at 50c. asked. Reports on the fishing operations along the Atlantic coast were unfavorable. Some traders look for a "lean" year. Newfoundland cod oil was offered in a small way and prices held at 70@72c. per gal.

Tallow and Greases—Extra special tallow closed at 7½c. bid, with the market for outside goods equal to extra at 7⅝c. sales. The undertone was a shade firmer. Yellow grease sold at 6c. per lb., Chicago. Oleo stearine was offered at 9c. per lb., carload lots, New York.

Miscellaneous Materials

Glycerine—The market for c.p. glycerine on spot was unsettled, but most refiners continued to quote on the basis of 17c. per lb., in drums, carload lots. Trading was inactive and this resulted in freer offerings from factors not so bullish on the general situation. In some directions c.p. glycerine might have been picked up around 16½c. per lb. In the middle-west dynamite was offered at 15½c. per lb., in drums, carload basis. No sales were reported in New York territory and prices at the close were nominal. Soaplye crude, basis 80 per cent, sold in the middle-west at 10½c. per lb., loose. Saponification, basis 88 per cent, held at 11½c. in the middle-west, while in New York 12c. was asked, carload lots, loose.

Naval Stores—The market advanced early in the week on a showing of business, but as soon as the inquiry fell away prices eased off. At one time scattered business in turpentine went through as high as \$1.10 per gal. Just before the close there were offerings at \$1.06 per gal., with the undertone easy. Receipts in the South were considered liberal. Export demand was slow. In rosins not much business came to light and prices went off from 10@15c. per bbl. The lower grades closed nominally at \$5.80 per bbl.

Shellac—The market was a shade firmer, on higher cables from Calcutta, but not much business developed. The arrivals were heavy and this brought out some ex-dock selling at concessions. Nominally the market for T.N. settled at 59c. per lb., with the superfine orange at 64c. per lb., and bleached bonedry at 72c. per lb.

Varnish Gums—The past week witnessed heavy importations of copals. Several shipments of damar also were noted. The spot offerings were liberal and it was possible to pick up supplies at concessions from the prevailing cost of import. Batavian damar settled at 27¾@28½c. per lb. Demand was routine.

White Lead, Etc.—Leading producers of white lead announced late last week that the guarantee against decline provisions in the sales contract would b extended until November 30. This new gave traders more confidence in the market and business held up well in all directions. Standard dry white lead held at 9¾c. per lb., in casks.

Zinc Oxide—The easier market for the metal had little or no influence upon prices for oxide. Producers appear to be well sold up and the old price schedule was maintained in all directions. American process, lead free, was traded in on the basis of 8c. per lb. French process, red seal, held at 9¾c. per lb.

London Tallow Auction

At the regular auction of tallow, held in London June 13, the offerings consisted of 1,685 casks. Sales amounted to 1,283 casks and prices realized were unchanged to 6 pence higher.

QUICKSILVER—26 flasks, Tampico, J. Elizondo; 30 flasks, Seville, C. L. Huisking, Inc.; 250 flasks, Seville, Du Pont de Nemours & Co.

QUEBRACHO—17,800 bg. extract, Buenos Aires, Tannin Corp.; 4,206 bg. Buenos Aires, Beekman, Winthrop & Chartman.

SAL AMMONIAC—88 csk., Hamburg, Philipp Bauer Co., 44 csk., Hamburg, Innis, Speiden & Co.

SHELLAC—50 bg. garnet lac, Hamburg, Irving Bank-Col. Trust Co.; 205 cs stick lac, Bangkok, Order; 163 csk. stick lac, Marseilles, Order; 300 bg., Calcutta, Chase National Bank; 232 bg., Calcutta, National City Bank; 1,225 bg refuse, Calcutta, Bank of the Manhattan Co.; 100 bg., Calcutta, London & Liverpool Bank of Comm.; 25 bg., Calcutta, Bank of America; 50 bg., Calcutta, Mechanics & Metals National Bank; 50 bg., Calcutta, Standard Bank of South Africa; 1,358 bg., Calcutta, Order; 112 cs., Calcutta, Order; 600 bg., Calcutta, First Nat'l Bank of Boston; 250 bg., Calcutta, Mech. & Metals Nat'l Bank; 200 bg., Calcutta, Br. Bank of So. Am.; 871 bg., Calcutta, Order; 30 bg., Hamburg, Kasebier-Chatfield Shellac Co.

SODIUM SALTS—300 bg. chlorate, Hamburg, Order; 110 bg. fluosilicate, Hamburg, Order; 49 cs chlorate, Venice, Order; 112 cs. cyanide, Marseilles, National City Bank; 120 csk hyposulphite, Marseilles, Order; 190 dr. caustic, Hamburg, A. Klipstein & Co.; 223 dr. sulphide, Hamburg, Order; 49 csk. fluoride, Hamburg, Order; 25 bbl. bicarbonate, Hamburg, K. A. Blank.

SUMAC—10 bg., Glasgow, American Dyewood Co.

TALLOW—500 pkg. vegetable, Hankow, American Linseed Co.; 190 tcs. beef, Vancouver, Van Iderstine Co.; 299 tcs. beef, Rio Grande do Sul, Swift & Co.

TANNING EXTRACT—700 bg., Beira, Cooper & Cooper.

TARTAR—39 csk., Naples, Tartar Chemical Works; 9 csk., Naples, C. B. Richard & Co., 578 sks., Marseilles. Tartar Chemical Co.; 110 pkg., Marseilles, C. Pfizer & Co.; 351 sk., Alicante, C. Pfizer & Co.

WAXES—600 bg. montan, Bremen, Order; 128 bg. bees, Antwerp, Order; 5 bg. bees, Santiago, Order; 79 bg. bees, Rio de Janeiro, London & Brazilian Bank; 150 bg. do., Rio de Janeiro; American Trading Co.

WOOL GREASE—100 bbl., Hull, Marden Wild Corp.

WHITING—1,000 bg., Antwerp, Bankers' Trust Co.

XYLENE—5 dr., London, Van Oppen & Co.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb.	$0 38	
Acetone, drums	lb	25 -	25½
Acid, acetic, 28%, bbl	100 lb	3 38 -	3 50
Acetic, 56%, bbl	100 lb	6 75 -	7 00
Glacial, 99½%, bbl	100 lb	12 00 -	12 50
Boric, bbl	lb	.10½-	
Citric, kegs	lb	.49 -	52
Formic, 85%	lb.	14 -	16
Gallic, tech.	lb	45 -	50
Hydrofluoric, 52%, carboys	lb	11 -	12
Lactic, 44%, tech., light, bbl.	lb	11½-	12
22% tech., light, bbl	lb	05½-	06
Muriatic, 18° tanks	100 lb	90 -	1 00
Muriatic, 20°, tanks	100 lb.	1 00 -	1 10
Nitric, 36°, carboys	lb	04½	05
Nitric, 42°, carboys	lb.	06 -	06
Oleum, 20%, tanks	ton	18 50 -	19 00
Oxalic, crystals, bbl.	lb.	.13 -	
Phosphoric, 50% carboys	lb	07½-	08
Pyrogallic, resublimed	lb	1 50 -	1 60
Sulphuric, 60°, tanks	ton	9 50 -	11 00
Sulphuric, 60°, drums	ton	13 00	14 00
Sulphuric, 66°, tanks	ton	16 00 -	16 50
Sulphuric, 66° drums	ton	20 00 -	21 00
Tannic, U S P, bbl	lb.	.65 -	.70
Tannic, tech., bbl	lb.	.45 -	.50
Tartaric, imp., powd, bbl.	lb	.35½-	36
Tartaric, domestic, bbl.	lb	.37½-	
Tungstic, per lb	lb.	1 10 -	1 20
Alcohol, butyl, drums, f o b works	lb.	.26 -	.28
Alcohol ethyl (Cologne spirit), bbl	gal.	4 75 -	4 95
Ethyl, 190 p'f U S P, bbl	gal	4 70	
Alcohol, methyl (see Methanol)			
Alcohol, denatured, 190 proof			
No 1, special bbl	gal.	41 -	
No. 1, 190 proof, special, dr	gal	35 -	
No 1, 188 proof, bbl	gal	42	
No. 1, 188 proof, dr	gal	36 -	
No 5, 188 proof, bbl	gal	40 -	
No. 5, 188 proof, dr	gal	34 -	
Alum, ammonia, lump, bbl	lb	03½-	04
Potash, lump, bbl	lb	02¾-	03
Chrome, lump, potash, bbl	lb.	.05½-	05
Aluminum sulphate, com., bags	100 lb	1 50 -	1 65
Iron free bags	lb	.02½-	03
Aqua ammonia, 26°, drums	lb	06½	.07
Ammonia, anhydrous, cyl	lb.	.30 -	.30½
Ammonium carbonate, powd casks, imported	lb.	.09½-	10
Ammonium carbonate, powd. domestic, bbl	lb.	.13 -	.14
Ammonium nitrate, tech, casks	lb.	10 -	11
Amyl acetate tech, drums	gal.	3 50 -	3 75
Arsenic, white, powd., bbl	lb	13½-	.14
Arsenic, red, powd, kegs	lb	.15½-	16
Barium carbonate, bbl	ton	70 00 -	75 00
Barium chloride, bbl	ton	80 00 -	83 00
Barium dioxide, drums	lb.	.18 -	18½
Barium nitrate, casks		.08 -	08½
Blanc fixe, dry, bbl	lb.	.04 -	.04½
Bleaching powder, f.o.b. wks, drums	100 lb.	1 90 -	
Spot N. Y. drums	100 lb.	2.40 -	
Borax, bbl.	lb.	.05½-	05¾
Bromine, cases	lb.	28 -	.30
Calcium acetate, bags	100 lb.	4 00 -	4 05
Calcium arsenate, dr.	lb.	.16 -	16½
Calcium carbide, drums	lb.	05 -	05½
Calcium chloride, fused, drums	ton	22 00 -	23 00
Gran. drums	ton	28.00 -	30 00
Calcium phosphate, mono, bbl	lb.	.06½-	07
Camphor, cases	lb.	.86 -	.88
Carbon bisulphide, drums	lb.	.07 -	.07½
Carbon tetrachloride, drums	lb.	.09½-	.10
Chalk, precip.—domestic, light, bbl.	lb.	.04½-	04¾
Domestic, heavy, bbl	lb.	.03½-	.03¾
Imported, light, bbl	lb.	.04½-	.05
Chlorine, liquid, tanks, wks	lb.	.05½-	.05¾
Cylinders, 100 lb., wks	lb.	.06 -	.06½
Cylinders, 100 lb., spot	lb.	.09 -	
Chloroform, tech., drums	lb.	.35 -	.38
Cobalt oxide, bbl	lb.	2 10 -	2 25
Copperas, bulk, f.o.b. wks	ton	20 00 -	21.00
Copper carbonate, bbl	lb.	.19 -	.20
Copper cyanide, drums	lb.	.47 -	.50
Coppersulphate, dom., bbl.,	100 lb.	5.75 -	
Imp. bbl.	100 lb.	4.75 -	5.00
Cream of tartar, bbl	lb.	.25½-	.26½
Epsom salt, dom., tech., bbl	100 lb.	1.90 -	2 15
Epsom salt, imp., tech., bags	100 lb.	.90 -	1.00
Epsom salt, U.S.P., dom., bbl	100 lb.	2.50 -	2.60
Ether, U.S.P., resale, dr	lb.	.13 -	.15
Ethyl acetate, 85%, drums	gal.	.80 -	.81
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 -	1.00
Formaldehyde, 40%, bbl	lb	$0 14½ -	$0 15
Fullers earth—imp, powd, net	ton	30 00 -	32 50
Fusel oil, ref, drums	gal.	-	
Fusel oil, crude, drums	gal	3 50 -	3 75
Glaubers salt, wks, bags	100 lb	1 20 -	1 40
Glaubers salt, imp, bags	100 lb	90 -	95
Glycerine, c p, drums extra	lb	.16½	17
Glycerine, dynamite, drums	lb	15½-	16½
Glycerine, crude 80%, loose	lb	10½-	11
Iodine, resublimed	lb	4 55	4 65
Iron oxide, red, casks	lb.	.12 -	18
Lead:			
White, basic carbonate, dry, casks	lb.	.09¾-	10
White, basic sulphate, casks	lb	09½	
White, in oil, kegs	lb.	.12½-	14
Red, dry, casks	lb	.11½-	12
Red, in oil, kegs	lb.	13½-	.15
Lead acetate, white crys, bbl	lb	14 -	14½
Brown, broken, casks	lb	13	13
Lead arsenate, powd, bbl	lb.	23 -	24
Lime-Hydrated, bbl	per ton	16 80 -	17 00
Lime, Lump, bbl	280 lb	3.63 -	3 65
Litharge, comm, casks	lb	10½ -	11
Lithophone, bags	lb	.07 -	.07½
in bbl	lb	07½-	.07¾
Magnesium carb, tech, bags	lb	.08½-	.08½
Methanol, 95%, bbl	gal.	1 18 -	1 20
Methanol, 97%, bbl	gal.	1 20 -	1.22
Nickel salt, double, bbl.	lb.	10½-	
Nickel salts, single, bbl	lb	11½-	
Phosgene		60 -	.75
Phosphorus, red, cases	lb	-	
Phosphorus, yellow, cases	lb	35 -	.40
Potassium bichromate, casks	lb.	.11½-	.11¾
Potassium bromide, gran, bbl	lb	19 -	.20
Potassium carbonate, 80-85%, calcined, casks	lb.	.06½-	.06¾
Potassium chlorate, powd	lb.	.07½-	.08
Potassium cyanide, drums	lb.	.47 -	.52
Potassium, first sorts, cask	lb.	.08½	.08¾
Potassium hydroxide (caustic potash) drums	lb.	.07 -	.09
Potassium iodide, cases	lb.	3 65 -	3.75
Potassium nitrate, bbl	lb.	.06½-	.07½
Potassium permanganate, drums	lb.	.17½-	.19
Potassium prussiate, red, casks	lb.	65 -	67
Potassium prussiate, yellow, casks	lb.	.31 -	.33
Salammoniac, white, gran., casks, imported	lb.	.06 -	.06½
Salammoniac, white, gran, bbl, domestic	lb.	.07½-	.07¾
Gray, gran., casks	lb.	.08 -	.09
Salsoda, bbl.	100 lb.	1.20	1 40
Salt cake (bulk)	ton	26.00 -	28.00
Soda ash, light, 58% flat, bags, contract	100 lb.	1.60 -	1.67
Soda ash, light, basis, 48%, bags, contract, f.o.b. wks	100 lb.	1.20 -	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb.	1.75 -	1 80
Soda ash, dense, bags, contract, basis 48%	100 lb	1.17½-	1.20
Soda ash, dense, in bags, resale	100 lb.	1.85 -	1 90
Soda, caustic, 76%, solid, drums, f.a.s	100 lb.	3.20 -	3.30
Soda, caustic, basis 60%, wks., contract	100 lb.	2.50 -	2 60
Soda, caustic, ground and flake, contracts	100 lb.	3.80 -	3.90
Soda, caustic, ground and flake, resale	100 lb.	3.72½-	...
Sodium acetate, works, bags	lb.	.05½-	.06½
Sodium bicarbonate, bbl	100 lb.	2.00 -	2.50
Sodium bichromate, casks	lb.	.08½-	.09
Sodium bisulphate (niter cake)	ton	6.00 -	7.00
Sodium bisulphite, powd., U.S.P., bbl	lb.	.04½-	.04½
Sodium chlorate, kegs	lb.	.06½-	.07
Sodium chloride	long ton	12.00 -	13.00
Sodium cyanide, cases	lb.	.21 -	.23
Sodium fluoride, bbl	lb	$0 08½ -	$0 10½
Sodium hyposulphite, bbl	lb	.02½-	.03
Sodium nitrite, casks	lb	.07½-	.08½
Sodium peroxide, powd., cases	lb.	.28 -	.30
Sodium phosphate, dibasic, bbl	lb	03½-	.04
Sodium prussiate, yel drums	lb	.14½-	16
Sodium salicylic drums	lb	47 -	52
Sodium silicate (40°, drums)	100 lb.	75 -	1.15
Sodium silicate (60°, drums)	100 lb.	1 75 -	2.00
Sodium sulphide, fused, 60-62% drums	lb.	.04½-	.04½
Sodium sulphite, crys, bbl	lb	.03½-	.03½
Strontium nitrate, powd, bbl.	lb	.12½-	.13
Sulphur chloride, yel drums.	lb.	04½-	.05
Sulphur, crude	ton	18.00 -	20 00
At mine, bulk	ton	16 00 -	18 00
Sulphur, flour, bag	100 lb.	2.25 -	2.35
Sulphur, roll, bag	100 lb.	2.00 -	2.10
Sulphur dioxide, liquid, cyl	lb.	.08 -	08½
Talc—imported, bags	ton	30.00 -	40.00
Talc—domestic powd, bags.	ton	18.00 -	25.00
Tin bichloride, bbl	lb.	.12½-	.13
Tin oxide, bbl	lb.	.48 -	...
Tin crystals, bbl	lb	.34½	.35
Zinc carbonate, bags	lb	.14 -	.14½
Zinc chloride, gran, bbl	lb.	.06½-	.06½
Zinc cyanide, drums	lb.	.37 -	.38
Zinc oxide, lead free, bbl.	lb.	.08 -	.08½
5% lead sulphate, bags	lb.	.07½-	......
10 to 35% lead sulphate, bags	lb	.07 -	......
French, red seal, bags	lb	.09½-	......
French, green seal, bags	lb.	.10½-	......
French, white seal, bbl	lb.	.12 -	......
Zinc sulphate, bbl	100 lb.	2.50 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb	$0.62 -	$0.75
Alpha-naphthol, ref., bbl	lb	.70 -	.80
Alpha-naphthylamine, bbl	lb.	.35 -	37
Aniline oil, drums	lb.	.16 -	.16½
Aniline salts, bbl	lb.	.23 -	24
Anthracene, 80%, drums	lb.	.75 -	1.00
Anthracene, 80%, imp., drums, duty paid	lb.	.70 -	.75
Anthraquinone, 25%, paste, drums	lb.	70 -	.75
Benzaldehyde U S.P., carboys	lb.	1 40 -	1.45
tech, drums	lb	75	80
Benzene, pure, water-white, tanks and drums	gal.	.27 -	.32
Benzene, 90%, tanks & drums	gal.	.25 -	.30
Benzene, 90%, drums, resale	gal.	.28 -	.32
Benzidine base, bbl.	lb.	.80 -	.85
Benzidine sulphate, bbl.	lb.	.70 -	.75
Benzoic acid, U.S.P, kegs	lb.	.75 -	.80
Benzoate of soda, U S P., bbl.	lb.	.57 -	.65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 -	...
Benzyl chloride, tech., drums	lb.	.30 -	.35
Beta-naphthol, tech., bbl	lb.	.21½-	.22½
Beta-naphthylamine, tech.	lb.	.80 -	.90
Cresol, U.S P., drums	lb.	.25 -	.29
Ortho-cresol, drums	lb.	.28 -	.32
Cresylic acid, 97%, resale, drums	gal.	1.15 -	1.20
95-97%, drums, resale	gal.	1.10 -	...
Dichlorbenzene, drums	lb.	.07 -	.09
Diethylaniline, drums	lb.	.50 -	.60
Dimethylaniline, drums	lb.	.41 -	.42
Dinitrobenzene, bbl,	lb.	.19 -	.20
Dinitroclorbenzene, bbl	lb.	.22 -	.23
Dinitronaphthalen, bbl	lb.	.30 -	.32
Dinitrophenol, bbl	lb.	.35 -	.40
Dinitrotoluene, bbl	lb.	.20 -	.22
Dip oil, 25%, drums	gal.	.25 -	.30
Diphenylamine, bbl	lb.	.50 -	.52
H-acid, bbl	lb.	.75 -	.80
Meta-phenylenediamine, bbl.	lb.	1.00 -	1.05
Michlers ketone, bbl	lb.	3.00 -	3.50
Monochlorbenzene, drums	lb.	.08 -	.10
Monoethylaniline, drums	lb.	.95 -	1.10
Naphthalene, flake, bbl	lb.	.08 -	.08½
Naphthalene, balls, bbl	lb.	.08½-	.09
Naphthionate of soda, bbl	lb.	.58 -	.65
Naphthionic acid, crude, bbl.	lb.	.55 -	.60
Nitrobenzene, drums	lb.	.10 -	.12
Nitro-naphthalene, bbl	lb.	.30 -	.35
Nitro-toluene, drums	lb.	.13½-	.14½
N-W acid, bbl	lb.	1.25 -	1.30
Ortho-amidophenol, kegs	lb.	2.30 -	2.35
Ortho-dichlorbenzene, drums	lb.	.17 -	.20
Ortho-nitrophenol, bbl	lb.	.90 -	.92
Ortho-nitrotoluene, drums	lb.	.10 -	.12
Ortho-toluidine, bbl	lb.	.13 -	.14½
Para-amidophenol, base, kegs	lb.	1.20 -	1.30
Para-amidophenol, HCl, kegs	lb.	1.25 -	1.35
Para-dichlorbenzene, bbl	lb.	.17 -	.20
Paranitroaniline, bbl	lb.	.70 -	.75
Para-nitrotoluene, bbl	lb.	.60 -	.65
Para-phenylenediamine, bbl.	lb.	1.45 -	1.50
Para-toluidine, bbl	lb.	.90 -	.95
Phthalic anhydride, bbl	lb.	.35 -	.38
Phenol, U.S.P., resale, dr	lb.	.42 -	.48
Picric acid, bbl	lb.	.20 -	.22
Pyridine, dom., drums	gal.	nominal	

Pyridine, imp., drums	gal.	$4 00 - $4.25
Resorcinol, tech., kegs	lb.	1.50 - 1 60
Resorcinol, pure, kegs	lb.	2.25 -
R-salt, bbl.	lb.	.55 - .60
Salicylic acid, tech., bbl.	lb.	.37 - .42
Salicylic acid, U.S.P., bbl.	lb.	.40 - .45
Solvent naphtha, water-white, drums	gal.	.27 - .32
Crude, drums	gal.	.24 -
Sulphanilic acid, crude, bbl.	lb.	.18 - .20
Thiocarbanilide, kegs	lb.	.35 - .38
Toluidine, kegs	lb.	1 20 - 1 30
Toluidine, mixed, kegs	lb.	.30 - .35
Toluene, tank cars	gal.	.30 - .35
Toluene, drums	gal.	.34 - .36
Xylidines drums	lb.	.49 - .50
Xylene, pure, drums	gal.	.75 - 1 00
Xylene, com., drums	gal.	.37 -
Xylene, com., tanks	gal.	.32 -

Naval Stores

Rosin B-D, bbl.	280 lb.	$5 80 -
Rosin E-I, bbl.	280 lb.	5 90 -
Rosin K-N, bbl.	280 lb.	6 10 -
Rosin W.G.-W.W., bbl.	280 lb.	6 25 - 7 25
Wood rosin, bbl.	280 lb.	5 90 - 6 00
Turpentine, spirits of, bbl.	gal.	1 06
Wood, steam dist., bbl.	gal.	.98 -
Wood, dest. dist., bbl.	gal.	.68 -
Pine tar pitch, bbl.	200 lb.	6 00
Tar, kiln burned, bbl.	500 lb.	- 13 00
Retort tar, bbl.	500 lb.	- 12 00
Rosin oil, first run, bbl.	gal.	.45 -
Rosin oil, second run, bbl.	gal.	.48 -
Rosin oil, third run, bbl.	gal.	.52 -
Pine oil, steam dist.	gal.	.70 -
Pine oil, pure, dest. dist.	gal.	.65 -
Pine tar oil, ref.	gal.	.48 -
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla.	gal.	.32 - .32½
Pine tar oil, double ref., bbl.	gal.	.75
Pine tar, ref., thin, bbl.	gal.	.25
Pinewood creosote, ref., bbl.	gal.	.52

Animal Oils and Fats

Degras, bbl.	lb.	$0 03½ - $0 04½
Grease, yellow, bbl.	lb.	.06½ -
Lard oil, Extra No. 1, bbl.	gal.	.90 - .92
Neatsfoot oil, 20 deg. bbl.	gal.	1.30 -
No. 1, bbl.	gal.	.92 - .94
Oleo Stearine		.09 -
Red oil, distilled, d.p. bbl.	lb.	.10½ - .10¾
Saponified, bbl.	lb.	.10½ - .10¾
Tallow, extra, loose	lb.	.07½ -
Tallow oil, acidless, bbl.	gal.	.94 - .96

Vegetable Oils

Castor oil, No. 3, bbl.	lb.	$0 14 -
Castor oil, No. 1, bbl.	lb.	.14½ -
Chinawood oil, bbl.	lb.	.28 -
Coconut oil, Ceylon, bbl.	lb.	.09½ -
Ceylon, tanks, N.Y.	lb.	.08½ .08½
Coconut oil, Cochin, bbl.	lb.	.09½ - .10
Corn oil, crude, bbl.	lb.	.12½ -
Crude, tanks, (f.o.b. mill)	lb.	.09½ -
Cottonseed oil, crude (f.o.b. mill), tanks	lb.	.10 -
Summer yellow, bbl.	lb.	.12½ - .13
Winter yellow, bbl.	lb.	.13½ - .13½
Linseed oil, raw, car lots, bbl.	gal.	1 10 -
Raw, tank cars (dom.)	gal.	1 05 -
Boiled, cars, bbl. (dom.)	gal.	1 12 -
Olive oil, denatured, bbl.	gal.	1 10 -
Sulphur, (foots) bbl.	lb.	.08 - .08½
Palm, Lagos, casks	lb.	.07 -
Niger, casks	lb.	.06½
Palm kernel, bbl.	lb.	.08½ - .08½
Peanut oil, crude, tanks (mill)	lb.	.12½ - .13
Peanut oil, refined, bbl.	lb.	.16½ -
Perilla, bbl.	lb.	.15½ - .16
Rapeseed oil, refined, bbl.	gal.	.83 - .84
Rapeseed oil, blown, bbl.	gal.	.88 - .89
Sesame, bbl.	lb.	.11½ - .12
Soya bean (Manchurian), bbl.	lb.	.12½ -
Tank, f.o.b. Pacific coast	lb.	.09½ - .09½
Tank, (f.o.b. N.Y.)	lb.	.10 -

Fish Oils

Cod, Newfoundland, bbl.	gal.	$0 70 - $0 72
Menhaden, light pressed, bbl.	gal.	.76 -
White bleached, bbl.	gal.	.78 -
Blown, bbl.	gal.	.82 -
Crude, tanks (f.o.b. factory)	gal.	.50 -
Whale No. 1 crude, tanks, coast	lb.	-
Winter, natural, bbl.	gal.	.76 - .78
Winter, bleached, bbl.	gal.	.79 - .80

Oil Cake and Meal

Coconut cake, bags	ton	$26 00 - $28.00
Copra, sun dried, bags, (c.i.f.)	lb.	.04½ - .05
Sun dried Pacific coast	lb.	.04½ - .04½
Cottonseed meal, f.o.b. mills	ton	36 00 -
Linseed cake, bags	ton	34 00 -
Linseed meal, bags	ton	36 00 -

Dye & Tanning Materials

Albumen, blood, bbl.	lb.	$0.45 - $0 50
Albumen, egg, tech., kegs	lb.	.90 - .95
Cochineal, bags	lb.	.33 - .35
Cutch, Borneo, bales	lb.	.04½ - .05
Cutch, Rangoon, bales	lb.	.13 - .13½
Dextrine, corn, bags	100 lb.	3 69 - 4.01
Dextrine, gum, bags	100 lb.	3.99 - 4.09
Divi-divi, bags	ton	38.00 - 39.00
Fustic, sticks	ton	30.00 - 35.00
Fustic, chips, bags	lb.	.04 - .05
Logwood, sticks	ton	26.00 - 30.00
Logwood, chips, bags	lb.	.02½ - .03½
Sumac, leaves, Sicily, bags	ton	70.00 - 72.00
Sumac, ground, bags	ton	$65 00 - $67 00
Sumac, domestic, bags	ton	40 00 - 42 00
Starch, corn, bags	100 lb.	2.97 - 3 07
Tapioca flour, bags	lb.	.06 - .06½

Extracts

Archil, conc., bbl.	lb.	$0 17 - $0 18
Chestnut, 25% tannin, tanks	lb.	.02 - .03
Divi-divi, 25% tannin, bbl.	lb.	.04 - .05
Fustic, crystals, bbl.	lb.	.20 - .22
Fustic, liquid, 42°, bbl.	lb.	.08 - .09
Gambier, liq., 25% tannin, bbl.	lb.	.08 - .09
Hematine crys., bbl.	lb.	.14 - .18
Hemlock, 25% tannin, bbl.	lb.	.04 - .05
Hypernic, solid, drums	lb.	.24 - .26
Hypernic, liquid, 51°, bbl.	lb.	.10 - .12
Logwood, crys., bbl.	lb.	.18 - .20
Logwood, liq., 51°, bbl.	lb.	.09 - .10
Quebracho, solid, 65% tannin, bbl.	lb.	.04½ - .05
Sumac, dom., 51°, bbl.	lb.	.06½ - .07

Dry Colors

Blacks-Carbongas, bags, f.o.b. works	lb.	$0 20 - $0 24
Lampblack, bbl.	lb.	.12 - .42
Mineral, bulk	ton	35 00 - 45 00
Blues Bronze, bbl.	lb.	.55 - .60
Prussian, bbl.	lb.	.55 - .60
Ultramarine, bbl.	lb.	.08 - .35
Browns, Sienna, Ital., bbl.	lb.	.06 - .14
Sienna, Domestic, bbl.	lb.	.03½ - .04
Umber, Turkey, bbl.	lb.	.04 - .04½
Greens-Chrome, C.P. Light, bbl.	lb.	.32 - .34
Chrome, commercial, bbl.	lb.	.12 - .12½
Paris, bulk	lb.	.28 - .30
Reds, Carmine No. 40, tins	lb.	4 50 - 4 70
Oxide red, casks	lb.	.10 - .14
Para toner, kegs	lb.	1 00 - 1 10
Vermilion, English, bbl.	lb.	1 30 - 1 32
Yellow, Chrome, C.P. bbls.	lb.	.20 - .21
Ocher, French, casks	lb.	.02½ - .03

Waxes

Bayberry, bbl.	lb.	$0 30 - $0 32
Beeswax, crude, bags	lb.	.20 - .21
Beeswax, refined, light, bags	lb.	.32 - .34
Beeswax, pure white, cases	lb.	.40 - .41
Candelilla, bags	lb.	.20½ - .21½
Carnauba, No. 1, bags	lb.	.42 - .43
No. 2, North Country, bags	lb.	.23 - .23½
No. 3, North Country, bags	lb.	.18½ - .19
Japan, cases	lb.	.15 - .16
Montan, crude, bags	lb.	.04½ - .04½
Paraffine, crude, match, 105-110 m.p.	lb.	.04 - .04½
Crude, scale 124-126 m.p., bags	lb.	.02½ - .03
Ref., 118-120 m.p., bags	lb.	.03 - .03½
Ref., 125 m.p., bags	lb.	.03½ - .03½
Ref., 128-130 m.p., bags	lb.	.03½ - .03½
Ref., 133-135 m.p., bags	lb.	.04 - .04½
Ref., 135-137 m.p., bags	lb.	.05 - .05½
Stearic acid, sgle pressed, bags	lb.	.12½ - .12½
Double pressed, bags	lb.	.13 - .13½
Triple pressed, bags	lb.	.14½ - .14½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3 25 - $3 30
F.a.s. double bags	100 lb.	3 85 - 3 90
Blood, dried, bulk	unit	4 00 -
Bone, raw, 3 and 50, ground	ton	27 00 - 30 00
Fish scrap, dom., dried, wks.	unit	3 75 -
Nitrate of soda, bags	100 lb.	2 45 - 2 52½
Tankage, high grade, f.o.b. Chicago	unit	3 60 - 3 70
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$4 00 - $4.50
Tennessee, 78-80%	ton	8 00 - 8 25
Potassium muriate, 80%, bags	ton	34 55 -
Potassium sulphate, bags basis 90%	ton	43 67 -
Double manure salt	ton	25 72 -
Kainit	ton	7 22 -

Crude Rubber

Para—Upriver fine	lb.	$0 28½ -
Upriver coarse	lb.	.26 -
Upriver caucho ball	lb.	.26½ -
Plantation—First latex crepe	lb.	.27½ -
Ribbed smoked sheets	lb.	.27½ -
Brown crepe, thin, clean	lb.	.25½ -
Amber crepe No. 1	lb.	.27½ -

Gums

Copal, Congo, amber, bags	lb.	$0.12 - $0 13
East Indian, bold, bags	lb.	.23 - .23½
Manila, pale, bags	lb.	.20 - .20½
Pontinak, No. 1 bags	lb.	.20 - .20½
Damar, Batavia, cases	lb.	.28 - .28½
Singapore, No. 1, cases	lb.	.34 - .35
Singapore, No. 2, cases	lb.	.23 - .23½
Kauri, No. 1, cases	lb.	.65 - .67
Ordinary chips, cases	lb.	.21 - .22
Manjak, Barbados, bags	lb.	.09 - .09½

Shellac

Shellac, orange fine, bags	lb.	$0.62 -
Orange superfine, bags	lb.	.64 -
A. C. garnet, bags	lb.	nominal
Bleached, bonedry	lb.	.72 -
Bleached, fresh	lb.	.60 -
T. N., bags	lb.	.59 -

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$500.00 -
Asbestos, shingle, f.o.b., Quebec	sh. ton	$65.00 - $85 00
Asbestos, cement, f.o.b., Quebec	sh. ton	20.00 - 25 00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 - 20 00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13.00 - 15 00
Barytes, floated, f.o.b. St. Louis, bbl.	net ton	28.00 -
Barytes, crude f.o.b. mines, bulk	net ton	10 00 - 11 00
Casein, bbl., tech.	lb.	.17½ - .18½
China clay (kaolin) crude, f.o.b. Ga.	net ton	7.00 - 9 00
Washed, f.o.b. Ga.	net ton	8.00 - 9 00

Lead, tea	3.50@ 3.7
Brass, heavy	6.50@ 6.7
Brass, light	5.75@ 6.0
No. 1 yellow brass turnings	6.75@ .70
Zinc	3.75@ 4.2

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	\$3.29	\$3.14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

Alabama

FLINT The Southern Rock Asphalt Co., recently formed with a capital of \$600,000, has plans under way for the construction of a local refining plant, estimated to cost in excess of \$100,000, with machinery. Equipment for asphalt mining will be installed on local property. L. D. Powell is general manager.

BIRMINGHAM—The Murray Tire Co. has work nearing completion on a new plant at 27th Ave. and 26th St. and plans to install machinery and place the works in service at an early date. The company recently increased its capital to \$200,000, for expansion.

California

LOS ANGELES—The French China Co, Sebring, O. has preliminary plans under consideration for the construction of a new pottery on site now being selected near Los Angeles, totaling about 100 acres. It will consist of a number of buildings, estimated to cost approximately \$1,000,000, with machinery. O. H. Sebring is president.

LONG BEACH—The Specialty Glass Co is having plans completed for the erection of a new plant on local site, recently purchased It will cost approximately \$45,000. The H. L. Dixon Co, Rosslyn Rd, Pittsburgh, Pa, is engineer

INDIO—The Interlocking Tile & Sewer Pipe Co, Ontario, Calif, is perfecting plans for the erection of a new plant in the vicinity of Indio, estimated to cost about \$75,000. J F. Gale and D. E. Bulger head the company.

Connecticut

MERIDEN—The Wolf New Process Abrasive Wheel Co, Inc., Hanover St, will break ground at once for the erection of a 1-story addition to its plant A general contract for the work has been awarded to Lewis A. Miller, Meriden

WINDSOR LOCKS—C H. Dexter & Sons, Inc, has broken ground for the construction of a new 4-story and basement building at its paper mill, 55x100 ft The general contract has been let to the R. G. Bent Co, 83 Ann St, Hartford, Conn Greenwood & Noerr, 847 Main St., Hartford, are engineers

Florida

TAMPA—The Roesch Paper Co., Hampton and Franklin Sts., has plans under way for the erection of a new 3-story plant. 100x150 ft., on South Florida Ave, to more than double the capacity of its present plant. It is purposed to remove the existing works to the new location and install considerable additional machinery. Henry Roesch is president.

LEESBURG—The Florida China Clay Co., recently organized, is planning for enlargements in its commercial clay plant to increase the present output of about 50 tons per day. Additional machinery will be installed. J. S Morris is president and manager, and L. A. Morris, secretary and treasurer.

LAKE CITY—The Lake City Dehydrating Co. is planning for the erection of a new plant, 42x100 ft. A. K. Purdy is president and manager

Illinois

CHICAGO—The American Linseed Oil Co., 2209 Lumber St., will soon commence the rebuilding of the portion of its plant recently destroyed by fire, to be 4-story, 70x100 ft., estimated to cost \$80,000. Francisco & Jacobus, 39 South La Salle St., are architects. R. H. Adams is president.

BLUE ISLAND—Fire, May 30, destroyed a portion of the vat department at the refining plant of the Consumers Oil Co., with loss estimated at \$22,000. It is planned to rebuild.

Kansas

COFFEYVILLE—The Sinclair Consolidated Oil Corp, 45 Nassau St., New York, will make extensions and improvements in its local refining plant, including the installation of additional equipment. Enlargements will also be carried out at the oil and gasoline refineries at Kansas City, Kan.; East Chicago, Ind.; Cushing, Okla., and other locations. A new refining plant is now being constructed at Marcus Hook, Pa., and is expected to be ready for service at an early date.

Louisiana

HAMMOND—The Louisiana Utilities Mfg. & Agricultural Co, recently formed with a capital of \$1,000,000, has preliminary plans under consideration for the construction of a commercial fertilizer plant, in connection with local utility properties. H. G. Hungate is secretary.

SHREVEPORT—The Henderson Cotton Oil Co. will commence the immediate rebuilding of the portion of its plant, recently destroyed by fire. It will cost close to \$25,000.

Maryland

BALTIMORE—The Cast Stone Products Co., 16 South Eutaw St., will commence the erection of a new plant at 3rd and Maryland Aves., Brooklyn district, for the manufacture of blocks, hollow tile and other cast stone specialties

Massachusetts

WEST SPRINGFIELD—The General Fibre Box Co., Circuit Ave., has awardede a general contract to the Samuel M. Green Co., 293 Bridge St., Springfield for the construction of a new 1-story building at its plant, 96x100 ft

Michigan

DETROIT—Berry Brothers, Inc., foot of Leib St., manufacturer of varnishes, oils, etc, has acquired property adjoining its plant, formerly occupied by the Detroit Heating & Lighting Co., and will raze two of the three buildings on the site for the erection of new plant additions. A 4-story extension will be built at once, to be equipped as a color-grinding works. Frederick L. Colby is president, and W. R. Carnegie, vice-president and general manager.

MONROE—The Monroe Board & Lining Co., Barberton, O., has work under way in the first unit of a new mill, 200x300 ft, and plans to occupy the structure at an early date for the manufacture of corrugated board and other paper products. The present Barberton plant will be removed to the new location and additional equipment installed. Other plant units will be built later. William G. Gutmann is president, and J. D. Miller, vice-president, treasurer and general manager.

Nevada

RENO—The Nevada Magnesite Products Co, recently organized, is planning for the construction of a plant for the production of artificial stone products, including tiles, blocks, etc., utilizing magnesite under a special process. A large raw material deposit has been secured about 8 miles from Reno. Charles H. McCarthy is president, and Paul Butler, vice-president.

New Jersey

BEVERLY—The Beverly Wall Paper Co. has plans in progress for the erection of a new 1-story building at its plant, 60x200 ft. Harry G. Aitkin, American Mechanics Bldg., Trenton, N. J., is architect.

LYNDHURST—The Century Cement Products Co. is planning for enlargements in its local plant, to include the installation of additional machinery. The company specializes in the manufacture of blocks, tile and kindred products under a special process. John H. McGuire, Passaic, N. J., mayor of that city, is president and David Slayback, vice-president and treasurer.

New York

PALMYRA—The Palmyra Packing Co., Inc., recently formed with a capital of $100,000, will operate a local plant for the manufacture of rubber, asbestos and other industrial packings. Plans are being arranged for early production. John N. Todd, Canandaigua St., heads the company.

NEW YORK—The American Smelting & Refining Co., 120 Broadway, has tentative plans under way for the construction of coke ovens and a byproducts plant in the vicinity of its properties in the Rosita coalfield, Sabines, State of Coahuila, Mexico. An appropriation of more than $2,500,000 has been arranged for this and other expansion work in that district. The coke production will be used at the company's smelting plants at Chihuahua, Monterey, Asarco and Calientes, Mexico.

PLATTSBURG—A new company is being organized by H. P. O. Newstrand, Greenwich, N. Y., to operate a paper mill at Plattsburg. The former Lezier mill has been acquired and it is purposed to construct a 1-story addition to cost about $75,000.

Ohio

CINCINNATI—The Mammolith Carbon Paint Co., Cincinnati, has been acquired by new interests, headed by J. H. Kresge, Pittsburgh, Pa., for a consideration said to be about $300,000. The new company has plans for extensions and improvements for larger capacity. The carbon mines in Arkansas, also purchased, will be expanded.

COLUMBUS—The Brocalsa Chemical Co. has plans in progress for extensions and improvements in its plant and properties at Syracuse, O., and vicinity. Additional equipment will be installed. The company is arranging for a bond issue of $500,000, a portion of the proceeds to be used for the expansion.

LOWELLVILLE—The Grasselli Powder Co. has plans under consideration for the rebuilding of the portion of its local plant, including press and corning mills, destroyed by fire, June 6. An official estimate of loss has not been announced. Headquarters of the company are in the Guardian Bldg., Cleveland, O.

NORTH INDUSTRY—The Stark Oil Refining Co., 1110 George D. Harter Bank Bldg., Canton, O., has plans in progress for the erection of a new local oil-refining plant, estimated to cost approximately $350,000, including equipment. Edward Keiser heads the company. Walter Cross, Kansas City, Mo., is engineer.

Oregon

SALEM—The Oregon Pulp & Paper Co. will take bids at once for the erection of a 2-story addition to its mill, 128x220 ft., estimated to cost about $100,000, including equipment. Knighton & Howell, United States National Bank Bldg., Portland, are architects.

Pennsylvania

BRISTOL—The Paterson Parchment Paper Co., Modena, Pa., has construction under way on a new local mill, to comprise about 5 acres of floor space, estimated to cost close to $2,000,000, with machinery. To provide for a portion of the work, the company is disposing of a bond issue of $1,500,000. A plant is now being operated at Modena, and a parchmentizing mill at Passaic, N. J. It is purposed to double the present output. William F. Brunner is president.

PITTSBURGH—The Pennzoil Co., Oil City, Pa., formerly known as the Oil City Oil & Grease Co., has leased a building at 1739 Penn Ave. for a term of years, for the establishment of a new oil storage and distributing plant.

Tennessee

CLEVELAND—The Manufacturers' Soap & Chemical Co., recently organized with a capital of $50,000, has plans under way for the erection of a new 3-story plant for the manufacture of soaps, washing powders, etc. George S. Hardwick, Sr., is president.

Texas

HOUSTON—The Board of Directors, Rice Institute, will soon take bids for the construction of a new chemical laboratory at the institution, to be 3-story and basement, estimated to cost about $375,000. Twelve large laboratories will be installed, and sixteen smaller laboratories and research rooms. William Ward Watkin, Houston, is architect.

FORT WORTH—The Texas Steel Co., lately formed with a capital of $5,000,000, to take over and operate the local plant of the Armstrong Steel Co., will remodel and extend the works, providing an electric furnace department, steel and iron casting plant and steel bar mill. John H. Kirby, Houston, Tex., heads the new organization.

Vermont

SHELDON SPRINGS—The Missisquoi Pulp & Paper Co. has commenced the construction of a new unit at its local mill for considerable increase in capacity. Additional machinery will be installed and a power plant erected. The expansion is estimated to cost in excess of $400,000. The company specializes in the manufacture of bristol board.

West Virginia

WELLSBURG—The Specialty Glass Co., recently organized with a capital of $100,000, has plans under way for the erection of a new plant for the manufacture of a line of glass products, for which a local site will soon be selected. It is estimated to cost about $65,000, and is expected to be ready for service by the close of the year. The new company is headed by A. L. Rowing, Wellsburg; John N. Dean and A. E. Bowlder, Wheeling, W. Va.

Wisconsin

MANITOWOC—The Manitowoc Portland Cement Co., a subsidiary of the Newaygo Portland Cement Co., Newaygo, Mich., has plans nearing completion for the erection of a new cement mill on local site, consisting of a number of buildings, equipped for a capacity of 3,000 bbl. per day. It is estimated to cost approximately $1,500,000. To provide funds, the parent organization is disposing of a bond issue in the amount noted. Clay H. Hollister is president.

New Companies

BADER CHEMICAL CO., Passaic, N. J.; chemicals and chemical byproducts; $100,000. Incorporators: John Bader, Hans O. Hirsch and E. J. Zillessen, 353 Van Houten Ave., Passaic.

FLORIDA EAST COAST FERTILIZER CO., Miami, Fla.; fertilizer products; $200,000. M. C. Alford is president, and Thomas B. Nuttall, secretary, both of Miami.

ATLANTIC INDUSTRIAL ALCOHOL CO., Richmond, S. I., N. Y.; industrial alcohol and kindred products; $400,000. Incorporators: G. R. Franklin, F. T. Davis and M. E. Muniz. Representative: Bush & Crawford, 30 Broad St., New York.

LEA OIL CO., Boston, Mass.; refined oil products; 1,000 shares of stock, no par value. Arthur F. Ray is president, and Charles F. Dutch, 4 Brook St., Winchester, Mass., treasurer.

CENTRAL STEEL TREATING CO., Detroit, Mich.; heat-treating and hardening metals; $10,000. Incorporators: Karl B. Goddard, James I. McClintock and L. C. Dunn, 5324 Burns Ave., Detroit.

CITIZENS WINDOW GLASS CO., New Bethlehem, Pa.; glass products; $1,000,000. H. E. Andrews, New Bethlehem, is treasurer.

CRESCENT OIL CO., Martindale, Tex.; refined petroleum products; $50,000. Incorporators: R. E. Martindale, M. E. Barrow and E. L. Crook, all of Martindale.

GABIS OIL & CHEMICAL CORP., Linden, N. J.; chemicals, oils and kindred products; $25,000. Incorporators: A. J. David, M. S. Graff and Hyman Rosenfeld, Linden. The last noted is representative.

NORTH AMERICAN CHEMICAL CORP., New York, N. Y.; chemicals and chemical byproducts; $7,500,000. Incorporators: Maurice E. Davis, Ernest G. Metcalfe and Gotthilf Lehmann. Representative: United States Corporation Co., 65 Cedar St.

SAGADAHOC FERTILIZER CO., Bowdoinham, Me.; fertilizers and chemical products; $150,000. Horace S. Dodge, president and treasurer; and C. L. Andrews, Bowdoinham, clerk and representative.

MEMPHIS OXYGEN CO., Memphis, Tenn.; industrial oxygen products; $75,000. Incorporators: C. H. Reynoll, L. B. Lovitt and R. S. Polk, all of Memphis.

MACARTHUR MFG. CO., Seattle, Wash.; oil products; $100,000. William MacArthur, 521 Lyon Bldg., Seattle, heads the company.

FLAMINGO SUGAR MILLS, INC., Philadelphia, Pa.; construct and operate sugar mills; $100,000. A. W. Howe, Jr., 2032 De Lancey St., Philadelphia, is treasurer.

PAPER MILLS CORP., Wilmington, Del.; paper products, cardboard, etc.; $5,000,000. Representative: Corporation Trust Co. of America, du Pont Bldg., Wilmington.

TROMITE CORP., Carteret, N. J.; soap and kindred products; organized. Plun[illegible] Wheeler and Louis Neuberg, Carteret, he[illegible] the company.

PIGMY CORP., Marion, Ky.; to oper[illegible] fluorspar properties and reduction mil[illegible] $20,000. Incorporators: George B. Fra[illegible] and F. H. Burgher, Washington, Ky.; a[illegible] C. S. Nunn, Marion.

CHEMICAL SUPPLY CO., 5 Mount Vern[illegible] St., Providence, R. I.; chemicals and che[illegible]ical byproducts; organized. Philip [illegible] Lown heads the company.

EAST COAST OIL CO., Jacksonville, Fl[illegible] refined petroleum products; $500,000. I[illegible]corporators: George B. Monroe and D. [illegible] Anderson, both of Jacksonville.

FREEDOM PAPER CO., New York, N. Y.; paper products; $45,000. Incorporators: Friedland and M. Schlanger. Represent[illegible]tive: Isidore Lowenbraun, 116 Nassau S[illegible] New York.

CREZOIN CHEMICAL CORP., Camden, N. [illegible] chemicals and chemical byproducts; $25,000. Incorporators: Francis J. D. Bar[illegible] William B. and J. Benton Childers. Re[illegible]resentative: Adam R. Sloan, 531 Fede[illegible] St., Camden.

TEXAS CARBON INDUSTRIES, INC., Wilmin[illegible]ton, Del.; carbon and oil products; $650,0[illegible] Representative: Corporation Trust Co. [illegible] American, du Pont Bldg., Wilmington.

ATBLAKE LABORATORIES, INC., Syracu[illegible] N. Y.; chemicals and chemical byproduct[illegible] $25,000. Incorporators: J. G. Blaken[illegible] H. V. Curtiss and J. S. Atkins. Represent[illegible]tive: George W. O'Brien, The Bastab[illegible] Syracuse.

Industrial Notes

THE HERCULES POWDER CO. announc[illegible] the removal of its San Francisco office [illegible] the New Standard Oil Bldg., Bush a[illegible] Sansom Sts.

THE B. F. STURTEVANT CO., Hyde Par[illegible] Boston, Mass., announces that due to i[illegible]creased business and the desire to be [illegible] greater service to its customers, it has pu[illegible]chased the plant of the Wisconsin Engi[illegible] Co., maker of Corliss pumping engines [illegible] Corliss, Wis. This new acquisition cove[illegible] nearly 10 acres and the buildings have a[illegible]proximately 150,000 sq.ft. of floor space. [illegible] full manufacturing and engineering sta[illegible] will be maintained and closer co-operati[illegible] given to Western customers. The new pla[illegible] will be under the same direction as t[illegible] other factories at Hyde Park, Galt, Sa[illegible] Francisco and Philadelphia, with ex-Gove[illegible]nor E. N. Foss as president. Harry V[illegible] Page has been selected as general ma[illegible]ager and will be in entire charge of t[illegible] Wisconsin plant.

THE PENNSYLVANIA CRUSHER CO., Phil[illegible]delphia, Pa., in order to provide more ad[illegible]quate facilities for its business in the Pitt[illegible]burgh district, has moved the offices fro[illegible] the Peoples Bank Bldg., to the Oliver Bldg[illegible] where operations will be continued und[illegible] the management of H. M. Hallett.

R. M. SISK, vice-president and assista[illegible] treasurer of the Sharonville Boiler Work[illegible] Co., Sharpsville, Pa., recently severed h[illegible] connection with that company and has n[illegible] yet announced his plans for the future.

Opportunities in th[illegible] Foreign Trade

Parties interested in any of the followin[illegible] opportunities may obtain all available in[illegible]formation from the Bureau of Foreign an[illegible] Domestic Commerce at Washington or fro[illegible] any district office of the bureau. The num[illegible]ber placed after the opportunity must b[illegible] given for the purpose of identification.

BLACK DECOLORANT for bleaching. Turin, Italy. Agency.—6792.

CHEMICALS, OILS AND GREASES. Valparaiso, Chile. Agency.—6765.

DYES. Valparaiso, Chile. Agency.—6765.

PAINTS AND VARNISHES. Valparaiso, Chile. Agency.—6765.

LINSEED CAKE. Hamburg, Germany. Agency.—6756.

CASEIN. Dublin, Ireland. Purchase.—6744.

COCONUT OIL. 100,000 lb. Manzanillo, Mexico. Purchase.—6720.

GLUCOSE. Saloniki, Greece. Purchase.—6755.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY and IRON & STEEL MAGAZINE

Competition for Natural-Gas Supplies

AS A RESULT of the intensive search for petroleum, one of the largest natural-gas fields which the world has ever known was discovered near Monroe, La. This field lies more than 200 miles away from New Orleans and not much closer to any other prospective municipal user. As a consequence it is not at all likely that this territory can ever be profitably developed for city gas supply, since experience in other parts of the country indicates that pipe lines of such length are highly unprofitable investments with local regulation of the prices charged for gas. The question has been, therefore, and still remains, Who will use this natural gas to best advantage?

The first large users of natural gas in the Monroe field have been manufacturers of carbon black. Almost for the first time in history this use of gas has been encouraged by the federal government experts as perhaps the only economic method for the early development of this natural-gas territory. Now comes the question, however, as to whether other industries should not be encouraged to come in and use this splendid cheap fuel supply instead of allowing it to be consumed at rather low efficiency in the production of carbon black. Those who urge a change from the present policy insist that a larger number of workers and a greater value of finished product would result from many other industries using equivalent quantities of the gas. Those who contend on behalf of the carbon-black producer say that the other man can have the gas any time he is willing to pay more for it than it is worth for the manufacture of gasoline and carbon black under conditions now prevailing. Thus the carbon-black industry stands upon the dollars-and-cents argument—namely, that he who can afford to pay the most is entitled to the gas.

At the present time this question is decidedly acute. In fact, it is of such importance that the different groups within the Democratic party in that state are making an important campaign issue of the question of what should be done by the Governor and other state officials to control carbon-black manufacture in that state. As yet, however, there is no direct competition between industrial use and municipal gas supply. There is much talk about a pipe line to New Orleans; but capital will undoubtedly be very chary of making so large an investment with uncertain prospect as to the price that will be realized for the gas after it is delivered over these long distances. However, so long as there is threat of use for city supply, all gas-consuming industries are equally chary of making investments in this district.

Altogether this is another case where the best interest of the public is not being served because of extravagant claims or unjustifiable promises for cheap city supplies of natural gas. Such claims and promises never give a city any better gas supply and they certainly discourage that industrial development which is most wholesome and valuable for the community as a whole.

It will be well if officials and gas producers of the country at large refrain from encouragement of the public in the expectation of natural gas supplies from fields far distant from the municipal center. The officials and the producers will do far better for themselves, as well as for the public, by the encouragement of industrial developments for use of the gas, aiding either carbon-black plants or fuel-gas users who give promise of the greatest economic contribution to the community.

Awaiting A Moses

HUMBLE and chastened by the trials of the past few years, the fertilizer industry stands today hesitant as to the further road, but willing to follow leadership toward better business methods and the observance of those economic principles essential to permanent industrial success. There can be no question as to these facts in the mind of anyone who participated in the recent convention of the National Fertilizer Association.

There are few industries that have suffered more through the post-war period of depression, and almost no other prominent industry has remained so long in the period of hard times. This has been the inevitable consequence of the financial difficulties that have confronted the agricultural community. Without ready money, with severely curtailed income, and with exhausted credit, the farm interests as a whole have been unable to buy fertilizer in quantities comparable with their needs. But increased buying power of the farmers alone will not save the industry. There is need also of constructive, idealistic leadership; and this leadership must be such as to inspire the industry to follow into the ways of progress.

In the past the business methods, particularly the price cutting and conditional sales practiced by the industry, have been inexcusable. The extension of credit by the industry has been far beyond that limit fixed by sound business. The industry now recognizes these facts. It will be the first to admit that change in business practices must be made. The response to recommendations of this sort made at White Sulphur Springs was spontaneous and apparently unanimous.

But someone must show the way. It is not enough that the industry know the destination. A Moses to lead out of the wilderness of hard times, bad business practices and mutual distrust and suspicion is sorely

needed. Let him arise and the industry will gladly and obediently follow into a period of assured business success. No one can deny that the welfare of the entire nation demands greater use of fertilizer than has ever been practiced in this country; all will profit by right leadership.

The Radioactive Appliance as a Cure-All

TECHNOLOGY is continually being bombarded with questions propounded by the laymen as to the probable value of radioactive appliances the ostensible purpose of which appears to be to remedy almost all the ills that flesh is heir to. A satisfactory answer is difficult to formulate. The value of radium in medical work is indisputable, provided it is used with caution and by those with experience and knowledge. It is not surprising, therefore, that its curative powers have been exploited by the unscrupulous and the uninformed, although it is extremely difficult to substantiate a charge of fraud.

For instance, an enterprising individual might purchase a sufficient number of those luminous appendages that are used to hang on the electric-light cords, incase each in a pad and sell the article for the cure of rheumatism. Radium cures; the pad contains radium; where is the sting? Our manufacturer proclaims that "This company guarantees the —— —— —— pad to contain a definite quantity of actual radium." If his statement is questioned, he might retort that one-billionth part of one milligram is a definite quantity. When it comes to safeguarding the public against danger of burns, little trouble would be involved in proving that the radium in most of these appliances exists in so minute an amount that the possibility of physical injury to the wearer may be discounted. But whether such a pad as the one we have in mind could improve one's state of health, other than by auto-suggestion, is a problem that could be solved only by expert testimony and extensive investigation.

When the manufacturer of the radioactive pad departs beyond an elaboration of the simple statement that his apparatus contains radium and that radium may cure disease, he is likely to provide food for doubtful thought, if not evidence for conviction. It is well known, for instance, among scientists that the rate of emission of radiation from radium and radioactive substances cannot be controlled or altered or checked by human intervention. One manufacturer in California sells an appliance in which the radioactivity, according to the prospectus, may be "further increased by exposing the pad to sunlight, for," we learn, "the pad also possesses the property of absorbing the rays and radiant energy of the sun." Such a statement prompts inquiry into the good faith of the manufacturer and provides justification for suspicion; for the man who can develop an apparatus to insure the absorption of the "rays and radiant energy of the sun," which afterward can be "distributed throughout the system by placing the pad in contact with the body," has achieved what is unknown to science.

Another type of radioactive apparatus, also manufactured in California, purports to energize drinking water. It consists of a stoppered bottle in which there is a perforated container or cylinder, apparently of zinc or aluminum. The inventor and his Maker alone know what is inside this. Instructions indicate that the patient should drink four or five glasses of the water per diem, filling up the bottle with plain water after each withdrawal. This may be a device to persuade people with simple complaints to drink more water, the beneficial effect of which might be sufficient to deflect fame toward the manufacturer of the apparatus; or it may be that the generator provides an efficient method of treating water for effective medicinal purposes. We confess we do not know. However, it is to be noted that the apparatus is constructed so that the metals or other materials of which the cylinder is composed and incases continually produce a small amount of a very fine flocculent precipitate, the formation of which suggests to the chemically uninitiated that something effective is happening within.

The opinions of the American Medical Association on the subject of radioactive appliances such as those to which we have alluded should be worthy of dissemination. There is a great deal of misconception current; and many sufferers, physical and financial, are wondering whether the sale of radium for medicinal purposes should not be placed under control.

A Danger to Scientific Progress

THE REV. ARTHUR T. ABERNATHY offers to bet the Rev. HENRY VAN DYKE or "any other Biblical infidel" $1,000 that he—i.e., Dr. VAN DYKE et al.—cannot prove "the materialistic evolution of man out of a lower order of species."

It is our good fortune to know Dr. VAN DYKE as a faithful minister of the gospel, for many years a professor at Princeton University, United States Minister Plenipotentiary to Holland during the war until the entry of the United States, when he resigned to put on a uniform and go with the troops as chaplain; president of the American Institute of Arts and Letters, author, poet, traveler, a gentleman and a scholar. We venture to predict that he will not enter the betting ring with this Abernathy preach-wallah. But the incident brings up a timely question.

ABERNATHY is one of a type of heresy-hunters and persecutors that has obtained a considerable foothold in this country since the war. It is a recrudescence of the witch-burning of Salem, of the holy Inquisition of Spain, of the championing of hatred, malice and persecution that seems to crop up whenever the morale of civilization is low. Its exponents press their gospel of the denial of the right of man to think for himself. They are all the same: Fundamentalists, witch-burners and holy inquisitors. The Ku-Klux Klan is the fruit of this same illusion of ignorance, grafted upon the lay mind.

They are not of the intelligentsia. In so far as they boast of being "100 per cent American" they are the left-overs, the shorts that develop in every race from imprudent matings in earlier generations. They are natural-born haters. Just now the philosophy of evolution is their target, but that is merely incidental. Anything that they cannot understand will serve them equally well.

ABERNATHY shows his character when he declares that his fight is "against Christian ministers and teachers who . . . violate every principle of spiritual and intellectual integrity by accepting pay to proclaim

a set of principles . . . and then . . . teach antagonistic doctrine." He can't see any further than the dollars, although the few that clergymen receive are usually contributed by the parishes which they serve.

Evolution, we repeat, is a great system of philosophy. Nobody claims inspiration or immutability for it. It seems to the learned and intelligent to be a dim vision of the process of creation. It is constantly undergoing transition, and it is in no sense considered as the frozen words of dogma. Just now a great change is in process in the evident eclipse of WEISSMANN'S theory that acquired characteristics are not transmitted. One may believe in special creation and still believe in evolution. One may accept the theory in whole or in part. It does not beget hatred and malice except among the inferiors who can't understand it, or among vindictive men who, owing to a defective social order, have been able to gain a cloak of authority and who fear for the security of their commands.

There are certain formulas that are designed to satisfy minds of a low order that lack the gift of understanding. Of such are six days of creation and a flat earth. Or man as a perfect creature designed for erect walking. But men like ABERNATHY or the Rev. JOHN ROACH STRATON or WILLIAM JENNINGS BRYAN can't understand these things, and so they are angry and want to destroy those that can understand them.

The Fundamentalists of today are cruel, un-Christian, vindictive, and they are the champions of ignorance. They behave according to their natures, and we can't change that. But when they proceed to write their vicious notions into the laws of the land it is time to recognize them as the pests that they are. They are entitled to life, liberty and the pursuit of happiness, but to allow them to rule or to dictate means the destruction of our liberties and the death of progress.

Selling the Ultimate Consumer

FROM the viewpoint of extending public appreciation of the importance of the chemical engineering industries it is most unfortunate that so few of the products of these industries are recognizable as such by the ultimate consumer. We may be thankful, perhaps, for the extent that our manufacturers are thus relieved of catering to the evanescent whims of the consuming public, but we should not lose sight of the fact that serious problems are sometimes involved in the marketing and advertising of even the few chemical products that do reach the consumer directly.

An indication of the nature of these problems can perhaps best be brought out by considering a condition that might easily arise in almost any industry. Markets being established through national advertising, keen competition results in which one manufacturer may find himself at a decided disadvantage as regards access to supplies of certain raw materials. In an effort to retain his business he may find it possible to take other, more expensive raw materials and compound them in such a way as to produce a product that will present a more attractive appearance, although in reality it may be inferior to the original product for the purpose intended. Through intensive advertising this manufacturer may develop a wide public demand for his new, more attractive product, with the result that competing manufacturers are practically compelled to bring out a similar line in order to retain their share of the business. Even though the public is supplied with an inferior product, this condition may pass unnoticed for an indefinite period—simply because there may be no standards by which the individual can judge the relative efficiency of such products. Who can say, for instance, how little sodium silicate or how much naphtha should be used in a laundry soap? Is it safe to leave this to the housewife's preference, influenced as it is by some of the chemically ridiculous ads that grace the present-day billboard or magazine cover? Or should we insist on a more scientific basis of valuation and see that the public is converted to that basis?

National advertising, when rightly used, is a powerful tool for convincing the ultimate consumer of the inherent merits of those chemical products that pass directly to him. If in the past advertising has been misused to establish false standards of quality and usefulness, the responsibility lies with our own industries.

Curtailment Of Education

AT INTERVALS during the past few years various states have undertaken to regulate the operations of schools conducting their courses in foreign languages. On June 4 the Supreme Court of the United States passed upon such legislation, ruling that any such state or municipal statutes are unconstitutional. But there is another form of curtailment which cannot be regulated by court degree, and it is almost equally deserving of criticism. It is the suppression of scientific information and technical knowledge regarding progress in the arts and industries that results from an unduly selfish management policy.

This sort of restriction upon general progress is all the more to be condemned because of its very insidious nature, being justified in the minds of many on the score of the right of the individual to the exclusive use of his own achievements. Fortunately, however, it is constantly becoming more and more clear that this undue restraint upon the distribution of technical information is far from profitable to the management following this practice. Industries are coming to see that the more persons they can encourage to begin investigation and development work in fields of peculiar interest to themselves the more rapid will be the advance of their industries and the greater will be the rewards that come to themselves and their individual companies. The day of the patent written to conceal rather than reveal has passed; the courts have been emphatic in their rulings that such patents are not valid. The day of secret processes is also rapidly passing; there are far too many competent investigators working in almost every field for any management to hope that it can long retain exclusively and secretly any outstanding technical developments that its own staff may make.

The time has come when industry must cease its efforts to curtail public knowledge of products or processes. The unrestrained acquirement of knowledge must be encouraged, with the sole restriction that the rights of the inventor or the owner of the patent shall be adequately and honestly conserved under the patent laws. Greater secretiveness than this is not alone contrary to public interest; it is inexpedient for industry itself.

"The fertilizer business is a material business, but it is not necessary that we who have charge of its conduct should all turn into materialists. Ideals are necessary in business as well as in life, and without them we cannot succeed. As I see it, the industry, in the last 2 or 3 years, has been conducted on about a hundred per cent selfish basis."

A Challenge to an Industry

The President of the National Fertilizer Association, Frankly Criticising Some Business Practices, Makes a Stirring Appeal for Farsightedness

THE ADDRESS of the president of the National Fertilizer Association has always been filled with business statesmanship. It is a document which the business and technical world may well anticipate with eagerness. Not only does it present the progress and position of a great industry but it holds up to the membership and the world methods, standards and ideals that must inspire to saner business thinking and cleaner business practice.

Everyone knows of the difficulties which the fertilizer industry has been through—difficulties not only of prodigious, heartbreaking liquidation, of unbelievable frozen credits, but difficulties of unstable prices during the reconstruction period. This instability was caused by the disorganized, selfish scramble after business by a few who not only disorganized the market but failed to help themselves materially.

So much by way of background. Hear then the president: "I asked a man close to the industry about the association. He replied that he thought there was a better feeling, a broader acquaintance and more real friendship among the members of the association than any association with which he had ever come in contact, but, he added, there is less real co-operation."

"The co-operation which the members have so generously given to the officers of the association, often at great personal sacrifice, declines, when it becomes a matter of business, to about the square root of minus one. Some evidence on this can be inferred from the report of the Federal Trade Commission dealing with an investigation of the industry. The report is a clean bill of health, but the correspondence attached is not particularly edifying. It was the old army game of 'passing the buck,' but to an extent almost never equaled. It was always the other fellow who was at fault, never the man who was writing.

"The result of this spirit of selfishness has been chaos in many departments of the industry. There has been more talk and discussion of conditions the last 3 years than

Gustavus Ober, Jr.
President of the National Fertilizer Association

probably there was in the whole previous history of the business. The result of these discussions, where the analysis was carried far enough, was a statement that the difficulties of the industry were brought about by a lessened consumption on the part of the farmer. There was every readiness by the individual to recognize this and admit it, but there was no willingness to admit that that particular difficulty applied to the individual himself. It was a bad situation that must be borne by the other man.

"It is my firm conviction that individual prosperity is and can only be measured by the prosperity of the industry itself, and without prosperity in the industry there cannot be individual success. It may possible to beat the game for one season or more, but not over a period of years. Until this is realized, understood and accepted, there will be no foundation for future prosperity in the business. The fertilizer industry is itself, as has been stated repeatedly, basic and fundamental. There is a place for it and we all long for the day when it will again take its place as one of the best managed in the country.

"It has been said that Boston was not a place but a state of mind, and I sometimes think the industry has lost its standing as a business and has become a state of mind, and until that state of mind is changed, the industry will not prosper.

"The needs of the association, as I now see them, are re-establishment of confidence of each one in his fellow man. This means the elimination of insincerity, and, in many cases, actual hypocrisy, and an honest-to-goodness desire to co-operate intelligently with one another. I am frank to say this last, I think, has largely been lacking. If this can be accomplished, we shall be a long way toward better business methods and practices, and until these are re-established upon a firm and sound basis, I, for one, believe that prosperity cannot be achieved.

"The industry, as a whole, has drifted without anchor and at the mercy of any opportunist wind that blew. This has been reflected in the lack of a definite policy of many of the individual companies.

"Many of the individual representatives of the fertilizer business have definite convictions as to business principles and economic theories, but most of us have without hesitation thrown these overboard and subscribed to policies that we know in our own hearts were unsound and unsafe. I ask for the re-establishment of our convictions and ideals, and I believe that with such to guide us, we cannot go far wrong."

Such enlightened leadership must ultimately have its effect. The enthusiasm with which this address was greeted had a spontaneity that was unmistakable. With leadership and enthusiasm the industry will shake itself free, but not until the individual can visualize himself as a part of the whole, successful in its success and growing with its growth.

Conventions of National Fertilizer Association and Southern Fertilizer Association at White Sulphur Springs, W. Va., June 12 to 14, 1923, Deal With Industry's Problems of Production and Distribution

EDITORIAL STAFF REPORT

MORE "high-analysis" fertilizers and better selling methods were the two ideas that dominated the discussion at all sessions of both the National Fertilizer Association and the Southern Fertilizer Association, which held their meetings in White Sulphur Springs, W. Va., June 12 to 14. Each of these organizations was responsible for one of the open sessions; special meetings for consideration of the work of the soil improvement committee of the National Fertilizer Association and for executive discussion of some of the N.F.A. problems filled the remainder of the convention time.

The attendance, though not as large as during many former years, was at least 20 per cent above last year's. This and many other factors indicated an increasing confidence throughout the industry that the future business would be greater and more profitable. Although the individual companies composing the membership of this association have not been prosperous during the past few years, the association itself continued to show a good financial condition. The treasurer's report at the 1923 meeting indicated disbursements of approximately $18,000 and a generous balance still in the treasury. The secretary's report showed a net loss of only one member during the past year, a great contrast with the results during the preceding year, when the decrease in membership was 76.

Officers and Executive Committee Elected

As the five members of the executive committee who had served for the term ending 1923 were not eligible for re-election, the following five gentlemen were elected to succeed them for the term ending in 1926: L. A. Bailer, Swift & Co., Chicago; R. S. Cope, Reliance Fertilizer Co., Savannah, Ga.; W. D. Huntington, Davison Chemical Co., Baltimore; E. E. Newhouse, Arkansas Fertilizer Co., Little Rock, Ark.; A. E. Sheldon, Federal Chemical Co., Louisville, Ky.

All four officers of the association were re-elected to serve again for the coming year. They are: President, Gustavus Ober, Jr., G. Ober & Sons, Baltimore; vice-president, Spencer L. Carter, Virginia-Carolina Chemical Co., Richmond, Va.; treasurer, Irvin Wuichet, Wuichet Fertilizer Co., Dayton, Ohio; secretary, John D. Toll, *The American Fertilizer*, Philadelphia.

Presidential Address

Gustavus Ober, Jr., president of the National Fertilizer Association, not only reviewed the present situation in the industry as a national organization but also sounded words of warning and gave recommendations for further progress which proved the keynote of the proceedings of the convention. He urged a much broader view for the future, with especial attention to the elimination of bad practices which the industry as a whole seems willing to admit to be wrong. The time is ripe, in Mr. Ober's opinion, for these reforms, because liquidation of the industry appears practically complete, and reduction of the industry's indebtedness and the reduction of bad debts of users seems to have progressed as far as it can go.

Mr. Ober discussed the important progress which had been made through the Washington office of the association in legislative matters and through the great advances of the soil improvement committee, which has brought about the adoption of standard formulas for "high-analysis" goods. In this connection, however, he pointed out that too rapid an advance to high-analysis

product must not be expected, for immediate adoption of high analyses to the exclusion of all other brands would undoubtedly make impractical the use of certain valuable raw materials which should not be altogether eliminated.

The permanent prosperity of the industry demands, in his opinion, a great reform which must include three things:

1. A re-establishment of mutual confidence within the industry as to the honesty and fair dealing of other members of the business.

2. The elimination of unsound business principles in sales and uneconomic practices with respect to price-cutting, credits and business methods generally.

3. The re-establishment in the mind and practice of each individual, as well as of each company, of high ideals and high principles of practice.

Among the ends for which the association should strive are greater co-operation and co-ordination in research; the extension of the period of fertilizer purchase over longer times both spring and fall; uniform standards of nomenclature and standard formulas for commercial fertilizers; and a trade code of ethics for the guidance of the business. The last of these recommendations was developed at considerable length by Mr. Ober.

The spontaneous and hearty applause which greeted Mr. Ober's recommendations indicated that the association as a whole was prepared to accept this plan and follow this leadership.

Mixed Fertilizers in General Farming

Prof. Firman E. Bear, of the College of Agriculture, Columbus, Ohio, presented the one technical address of the association meeting, discussing the subject "Using Mixed Fertilizer in General Farming." He answered the question naturally raised in the minds of economists by the demonstration that the policy of using mixed fertilizer for general farming is sound. Professor Bear's paper is reproduced in slightly condensed form elsewhere in this issue.

Responding to Professor Bear's recommendations, Horace Bowker, of New York, congratulated him on the more practical and valuable service the agricultural stations of the country are now doing in fertilizer work. He pointed out that under the present conditions the industry and the investigators are working on such common basis as to permit active exchange of information to their mutual advantage.

What the Soil Improvement Committee Does

Prof. William D. Hurd, director of the soil improvement committee, reported briefly at the regular session of the association on the purposes and scope of the work carried on by this agency. This committee also held a special evening meeting at which an illustrated lecture descriptive of some of the achievements and methods of work by the staff of the committee was given. The scope of this committee's activity is best explained in the form of a brief statement and statistical summary which it presented to the membership on this occasion, answering the question: "What does the soil improvement committee (N.F.A.) do?"

It maintains a staff which is constantly in the field gathering facts for "The Fertilizer Story," and it spreads this through all available channels for the benefit of the whole industry.

It co-operates with all existing agencies "in procuring and disseminating useful knowledge and information pertaining to the scientific and practical development of agriculture."

It keeps in contact with soil-fertility developments in twenty-six states.

Its staff attends the principal agricultural meetings and conventions, making contacts with the leaders in soil-fertility work, gathering material, and keeping the viewpoint of the fertilizer industry before these workers.

It is a service organization to its subscribers.

It maintains research fellowships at Vermont, Maryland, Indiana, Wisconsin and Iowa Experiment Stations, for the study of important problems affecting the fertilizer industry.

It assists in carrying on co-operative fertilizer tests with experiment stations, county agricultural agents and other agencies on important crops.

It issues a "News Bulletin" which goes monthly to 9,500 college and experiment station workers, county agricultural agents, representatives of the industry, bankers, railroad agriculturists and others.

It has waged an active campaign to eliminate low analyses and the wasteful multiplicity of brands. Sectional meetings have been held in Chicago, Boston and Baltimore. State meetings of salesmen held in five states—more to follow. Nineteen states now co-operating.

It furnishes educational material to colleges, county agents, vocational instructors and the industry; 1,200 sets of charts on commercial plant food, 1,026 sets of experiment station photo panels, 36 sets of lantern slides and 11 exhibits are in constant circulation and use by these agencies.

It operates a "News Service" to farm and other papers. More than 1,200 articles, picture strips, news items, etc., were sent out to and used by nearly 500 papers having a circulation of more than 58,000,000 readers.

It distributes literature to subscribers, education agencies, etc. More than 150,000 copies were sent out during the year.

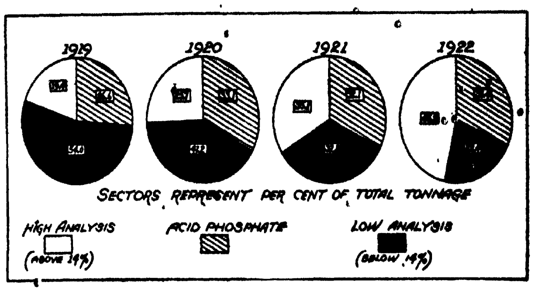

FIG. 1—PROGRESS OF HIGH ANALYSIS IN INDIANA
Prepared by soil improvement committee, National Fertilizer Association.

The outstanding achievement of the committee during the past year is unquestionably its work in securing the adoption of standard high-analysis fertilizer formulas in various districts of the country. This work, which has previously been reported in the news pages of *Chem. & Met.*, is illustrated by Fig. 1, showing the progress in adoption of high-analysis goods in Indiana during the past few years.

Cost Accounting Methods Recommended

On behalf of the cost accounting committee B. A. McKinney reported the great progress that has been made in the formulation of a system of cost accounting for companies that are engaged only in dry mixing. A system for companies manufacturing acid phosphate has not yet been developed, as this is a much more elaborate problem. The committee report on dry mixing is an elaborate text book of cost keeping and accounting methods. The committee felt this was essential since no simple outline of the classification of accounts would serve. The full report was not presented to the association in its general meeting, but was discussed in preliminary form at the executive sessions of the convention. It is planned that the changes and additions suggested as necessary by this executive consideration

be incorporated in the report and that it then be circulated in proof form for final comment before adoption. Pending this final criticism and revision, the report is not to be given out by the association except to members.

In the absence of C. F. Hagedorn, chairman of the chemical control committee, only a brief written communication describing this part of the association work was presented. During the past year the committee has been active in co-operation with the A.O.A.C. and the American Chemical Society in revision of methods of fertilizer analysis. The committee has recommended to the A.O.A.C. fertilizer referee certain definitions. Among these are a definition for basic phosphatic slag, which defines this as a material containing not less than 12 per cent P_2O_5, of which 80 per cent should be soluble; a definition for lime, providing that only oxide and hydroxide or equivalent magnesium compounds should be rated as available; and a definition of dry pulverized or shredded manure, which eliminates mixing other constituents.

The committee is giving particular attention to work on nitrogen availability. It urges further investigation on this subject as well as of methods for analysis of manure salts and for determination of ash.

Southern Fertilizer Association Meeting

One of the high lights of the convention week was the session on Tuesday, June 12, devoted to the mid-year meeting of the Southern Fertilizer Association. As members of this district association are also generally members of the national association, the attendance was excellent and the meeting was of great interest.

President J. Russell Porter, of the Porter Fertilizer Co., Atlanta, Ga., summarized the general feeling of the membership in his presidential address at the opening of the session. Distinct progress toward normal conditions and general encouragement of the industry was noted, with particular confidence because of the improved financial situation of most fertilizer users and the distinct progress that has been made by the soil improvement committee of the association. The president, however, cited two distinct notes of warning to the membership. The first was a warning against overproduction, an outstanding cause of curtailed profits; the second was an indictment of conditional sales, not alone because of their bad effects upon the industry itself but also because of the severe condemnation by others which these practices bring upon the industry.

As objectives for the coming year, Mr. Porter recommends abundant but not excessive production; sale at definite prices without undue extension of credit and without discounts; the increase in proportion of "high-analysis" goods; the elimination of as large a number of the unnecessary brands and kinds as possible; and encouragement of co-operative buying on a county basis rather than through state-wide contracts, which are impractical if not impossible of successful application.

Boll Weevil a Dominating Factor

The agricultural program of the South was discussed by Dr. J. M. Harper, the director of the soil improvement committee of the association. The respects in which this territory demands a different fertilizer program than the rest of the country was emphasized, with particular attention to the dominance of the boll weevil trouble in all phases of the subject. For real progress, Dr. Harper believes that the industry must encourage greater production per acre, and to this end he points out that "the intelligent use of fertilizer is the only answer to the problems of the industry." He prophesies that with the understanding of the boll weevil problems this pest can be controlled within a few years so that prosperity will return to the Southern agricultural territory. He estimates, therefore, an increased output of 500,000 to 1,000,000 tons per year for the eleven Southern states alone. On this basis, he forecasts an annual demand for not less than 7,000,000 tons of fertilizer in this territory within a period of approximately 5 years.

C. A. Whittle, boll weevil expert of the soil improvement committee, insisted that plowing under by Oct. 15 insures killing of at least 97 per cent of the boll weevil and that early use of poison, generally about June 15 to June 30, will adequately control the rest. Other systems of boll weevil control may be successful, but none of them has been proved sufficiently so to justify support by the fertilizer industry. In the practice of these two recommended methods, it should be understood that control on a community basis is essential, for migration from farm to farm offsets any advantage of control by the individual on his own land alone.

The growing belief that generous use of fertilizer for boll weevil control is a measure of value is somewhat justified; but the risk is too great for one to depend upon this, upon cultural methods, or upon other remedies without the use of calcium arsenate also. In the use of calcium arsenate, the most successful poison yet thoroughly tested, dusting is the best practice yet proved. Some liquid applications still in trial stages are probably going to be demonstrated to be of value, but

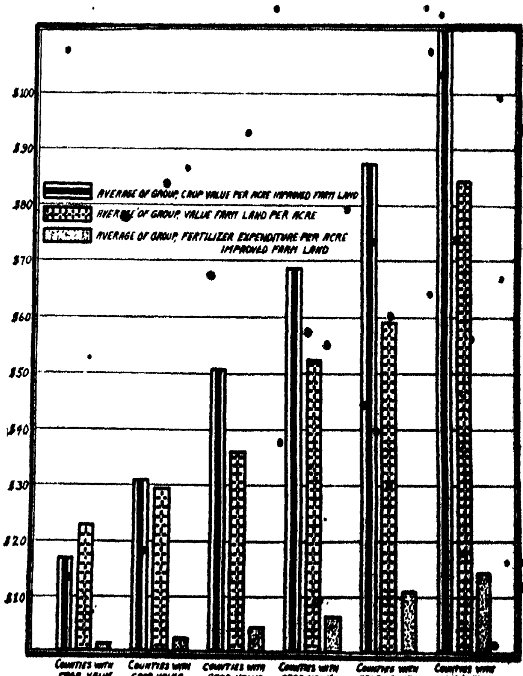

FIG. 2—CROP VALUES—FERTILIZER, EXPENDITURE—LAND VALUES

Showing relationship among these items for all counties of North Carolina, South Carolina and Georgia. Compiled from U. S. Census of 1920, by David D. Long, soil specialist, soil improvement committee, Southern Fertilizer Association.

one has yet reached the proved stage, in the judgment of Mr. Whittle.

With respect to the calcium arsenate situation in the South, Mr. Whittle pointed out that much delay had occurred in purchasing this year because of the belief that lower prices would follow and that perhaps the large quantities which were recommended for use might not be needed. He forecasts the crest of buying of calcium arsenate for about July 1. Until that peak of purchases is reached, it is difficult to tell whether the South will really experience a shortage.

Fertilizer Use and Crop Values

The diversification of crops in the South has long been urged as a means of improving agricultural conditions and protecting against the boll weevil. But D. D. Long, soil specialist and economist of the soil improvement committee, pointed out that this tendency to diversify agriculture was severely limited by economic facts. At present the South, considered on the basis of acreage, is really diversified in its agriculture, but the fact that cotton is valued at more than 50 per cent of all the crops shows that it is not well diversified in value of products. However, even with generous fertilization, it is difficult to substitute other crops for cotton, as the yield in dollars per acre is almost invariably much less. For example, oats, forage and other substitutes yield from $17 to $30 per acre, while cotton averages more than $80 per acre. Moreover, many of the substitutes suggested are not suited to the soil conditions of the South, and others, such as sweet potatoes and tobacco, which give high yields in dollars per acre and which are suited to much of the Southern territory, are crops of limited market demand.

From the standpoint of the fertilizer industry, the South must be sold its fertilizer on the basis of increasing crop value per acre and increasing market value of land, rather than upon any basis that the fertilizer will afford opportunity for much greater diversification of crops. To show the relation between fertilizer use and crop and land values, Mr. Long presented statistics in graphic form. Fig. 2, which groups all counties of the three states North Carolina, South Carolina and Georgia, the largest fertilizer using states of the country, shows most convincingly how both crop value per acre and land value per acre increase with increasing consumption of fertilizers. Similar charts which have been published recently in the *Fertilizer Green Book* show in detail for various other states and other crops that the same relationship holds—namely, that crop value and land value increase markedly with increasing fertilizer consumption.

Fertilizer Lowers Producing Costs

J. C. Pridmore, director of the soil improvement committee for the Shreveport district, discussed another phase of the relationship of fertilizer use to financial conditions at farm. Particularly he showed how the actual cost for lint cotton decreased per pound with increasing consumption of fertilizer and the attendant increase in yield. In one set of figures, an increase in yield from 100 to 300 lb. of lint per acre resulted in decrease from 30c. to 18c. per lb. as the net cost. Corresponding figures estimated for 1922 showed decrease from 25c. to 15c. as the net cost per pound of lint cotton.

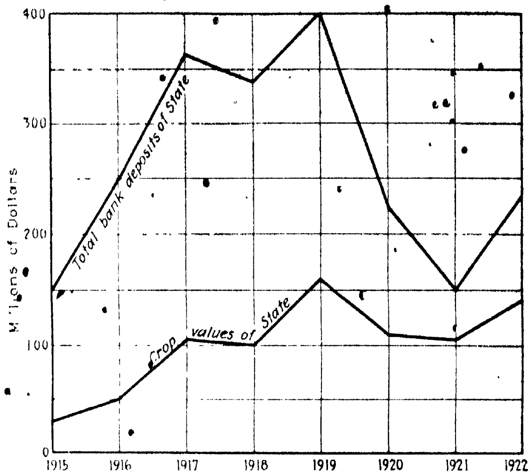

FIG. 3—RELATIONSHIP OF ARKANSAS CROP VALUE AND BANK ACCOUNTS

The increase in yields which produces this decrease in cost can be accomplished only by generous fertilizer application.

Financing Fertilizer Sales

Recognizing the criticism commonly made of the fertilizer industry for conditional sales and excessive credits in sale of fertilizers, Mr. Pridmore argued for a future development of credit by the local merchants and the local banks instead of by the fertilizer manufacturer. As evidence that the banks and merchants would be justified in granting such credit for fertilizer purchase, he showed the direct relationship between the value of crops, which of course depends upon quantity of fertilizer used, and the bank deposits of any season. Very striking figures are shown in Fig. 3, which applies to the entire state of Arkansas for the period 1915 to 1922, inclusive. In view of the great increase in prosperity resulting from fertilizer use, Mr. Pridmore argues that the banker would be amply justified in financing purchases of fertilizer if the industry would decline to give the large credits now afforded. In fact this willingness has already been shown in some districts, where improved conditions prevail.

Improved Selling Methods the Big Need

Discussing the industry as a whole, Mr. Ashcraft, of the Ashcraft-Wilkinson Co., Atlanta, urged in a vigorous manner an entire revision of the selling system of the Southern fertilizer industry. He pointed out as the great need of the present "the placing of really big men in the selling game." He urged, if no other way was found to accomplish it, that the cheap traveling salesman now employed be discharged and a limited number of high-caliber men who will take fair prices and stick to them be put in their place. At the present time the industry in the South "simply makes a price to cut it." As a consequence no one accepts seriously the prices quoted by the industry and the whole industry as a consequence is in disrepute.

The response to Mr. Ashcraft's arraignment of present practices indicates that the membership of the Southern Fertilizer Association is ready to accept this advice individually, if some means can be found for uniform practice of the methods proposed.

Calculation of Vapor Recompression Evaporators

By L. A. Pridgeon
Department of Chemical Engineering, University of Michigan

> **It is possible to calculate with a moderate degree of accuracy the heat economy and capacity of vapor recompression evaporators.**
>
> **The apparatus will come to equilibrium and establish its own temperature difference. This temperature difference is a direct function of the heat losses from the system.**
>
> **The power required is a direct function of the temperature difference.**
>
> **The economy is an inverse function of the temperature difference.**
>
> **Elevation of boiling point decreases the working temperature difference, and therefore decreases the capacity of a given heating surface.**

The essential organs of a vapor recompression evaporator are shown in Fig. 1. They are a preheater for heating the feed liquor with the condensate leaving the evaporator, an evaporator, and a compressor, which in this case is a motor-driven turbo-blower.

It should be noted that there are two parts to the fluid circuit, the high pressure, P_2, and the low pressure, P_1; also that any portion of the fluid traverses the circuit but once. The fluid enters the low-pressure circuit at the preheater as feed liquor, passes through the preheater into the body of the evaporator, vaporizes and leaves through the vapor line to the compressor. The fluid enters the high-pressure circuit at the discharge side of the compressor, passes to the steam basket, condenses, leaves the machine through the preheater and is collected in a trap below the evaporator.

The action of the machine may be studied to advantage in connection with the temperature-entropy diagram shown in Fig. 2. The vapor is drawn into the compressor through the suction pipe from the vapor space of the evaporator. It may be assumed that the vapor entering the compressor is in the saturated state at the temperature T_1, which may be taken equal to the temperature corresponding to the pressure P_1 in the vapor space of the evaporator. This state is represented by point B. The vapor is compressed adiabatically to a final pressure P_2, which is the pressure corresponding to the temperature T_2 of saturated steam in the steam basket. Adiabatic compression is represented by BC.

The superheated vapor in the state C is discharged into the steam basket, where heat is abstracted from it by the liquor in the evaporator. First the superheated vapor is cooled to the state of saturation; this process is represented by the line CD, and the heat abstracted by the area C_1CDD_1. Then heat is further removed at the constant temperature T_2 (and pressure P_2) and the vapor condenses. At the end of the process the fluid is in the liquid state. Its state is represented by the point E on the liquid curve, and the heat abstracted by the area D_1DEE_1. The condensate then leaves the steam basket and enters the preheater, where it is cooled to the temperature T_0 of the entering liquor. Its state is represented by the point F and the heat abstracted by the area E_1EFF_1.

The feed liquor enters the preheater at the temperature T_0, and its state is represented by the point F. In this theoretical case the temperature of the condensate leaving the preheater is taken as the temperature of the entering feed liquor. The reason for this is obvious from the discussion that follows. In practice, however, the temperature of the condensate leaving the preheater would be above that of the entering feed liquor. The temperature of the liquor entering the evaporator lies along the line FA. Assuming no elevation of boiling point, the liquor is raised to the temperature T_1, corresponding to the pressure P_1 of the vapor space. Its state is then represented by the point A, and the heat absorbed in raising its temperature from T_0 to T_1 is represented by the area F_1FAA_1. The temperature of the vapor in the steam basket being higher than that of the liquor, heat is absorbed by the liquor and it vaporizes at constant pressure P_1. This process is represented by the line AB and the heat absorbed from the vapor in the steam basket by the area A_1ABC_1.

The work done on the fluid is the difference between Q_1, the heat absorbed by the liquor, and Q_2, the heat rejected to the steam basket and preheater. We have then

$$Q_2 = \text{area } C_1CDEFF_1$$
$$Q_1 = \text{area } F_1FABC_1$$

The area F_1FAA_1 is common to both.

Therefore, if AW represents work expressed as heat units,

$$AW = \text{area } C_1CDEAA_1 - \text{area } A_1ABC_1 = \text{area } BCDEAB$$

In the cycle above described, the heat rejected to the steam basket and preheater is equal to the heat absorbed by the liquor, therefore $Q_2 = Q_1$ and $AW = 0$. In practice, a temperature difference must be maintained between the heating steam and the evaporating liquor, and a temperature difference consequently implies a pressure difference. Therefore AW cannot be equal to zero. Since work is done in maintaining this pressure difference, means must be provided for removing this work from the system in the form of heat. In this particular case this can be done in only two ways: heat removed by the thick liquor and by radiation. These being constant, AW is constant and therefore the temperature difference is constant and rather small.

The amount of heat added to any system in a given time must necessarily be taken away from the system in the same time if the initial condition of the system is to be maintained. So in our case if a specified temperature difference (which is a pressure difference) is to be maintained between the steam and boiling liquor by the compressor, the heat added by the compressor in the form of work must be removed. If the heat lost by radiation and through thick liquor discharge is not sufficient to remove all the heat added by compression.

Paper presented at the Wilmington, Del., meeting of the American Institute of Chemical Engineers, June 20-23, 1923.

it will be necessary to blow off steam from the vapor space. If steam were not blown off, the pressure of the vapor space would rise and thus decrease our temperature difference, thereby decreasing the work of compression and decreasing the heat added to the system in unit time. If the heat discharged from the system by radiation and through thick liquor is greater than that added by work of compression, heat must be added from some external source in order to maintain the specified temperature difference. If heat is not added from an external source, the temperature difference will increase until the work of compression is equal to the heat lost from the system by radiation and through thick liquor. With a given set of conditions it is impossible to maintain a predetermined temperature difference. The machine will come to equilibrium and maintain its own temperature difference. If no heat were lost from the apparatus, the boiling point would rise to that of the steam temperature, and there would be no temperature difference and consequently no evaporation. The temperature difference is a function of the net amount of heat lost from the apparatus per unit time.

Calculation of Work Required

The cycle of the vapor recompression evaporator transferred to the total heat-entropy plane is shown in Fig. 3. (This figure is a part of the Mollier diagram, which can be found in Marks and Davis' "Steam Tables and Diagrams.") The same letters in Figs. 2 and 3 denote the same states. Adiabatic compression is represented by BC, the point B lying on the saturation curve S'' (dry and saturated steam) at its intersection with the constant pressure line P_1. Line CE represents the cooling and condensation of the steam at constant pressure P_2, and line EF the cooling of the condensate in the preheater. The heat q_2 given up by unit weight of steam in the steam basket and by the condensate in the preheater is therefore the difference of thermal potential (total heat) between the states C and F:

$$q_2 = ic - if \quad (i = \text{total heat in 1 lb. of steam})$$

This heat is represented by the segment CF_1. Point E represents condensate at the pressure P_2 in the steam basket. Point A represents the state of the liquor in the evaporator. Point F represents the state of the condensate leaving the preheater and the state of the liquor entering the preheater. The process FA is the heating of the liquor in the preheater, and the process AB is the vaporization in the evaporator, during which heat q_1 is abstracted from the preheater and steam basket.

$$q_1 = ib - if$$

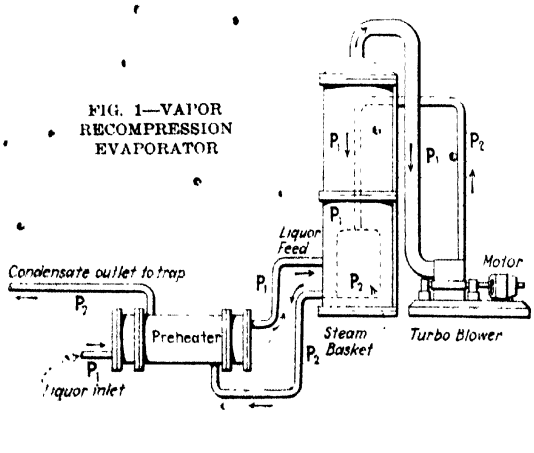

FIG. 1—VAPOR RECOMPRESSION EVAPORATOR

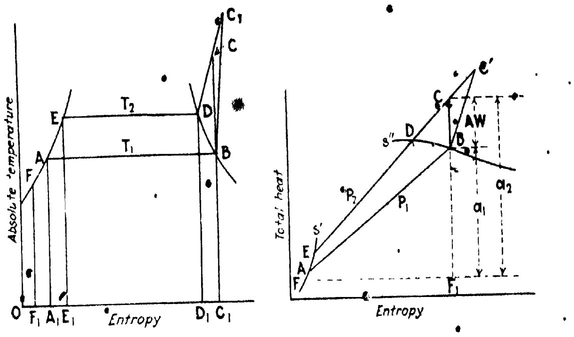


FIGS. 2 AND 3—TEMPERATURE-ENTROPY AND HEAT-ENTROPY DIAGRAMS

This heat is represented by the segment BF_1

$$AW = q_2 - q_1 = (ic - if) - (ib - if) = ic - ib$$

That is, the work required in thermal units is the change of thermal potential during the adiabatic compression.

If M equals the weight of liquid evaporated per hour, the work required per hour expressed in thermal units is $M\ (ic - ib)$, and the net power in kilowatts required to drive the machines $= M\ \dfrac{(ic - ib)}{3420}$

If n = efficiency of the compressor

$$\text{Gross kw.} = M\ \frac{(ic - ib)}{3420n}$$

The conceptions of steam compression differ from air compression in that adiabatic instead of isothermal compression is taken as 100 per cent efficiency. Steam compressors are not 100 per cent efficient. Internal friction between the moving parts and between the steam and its path through the compressor is converted into heat, which tends further to superheat the compressed vapor above that corresponding to adiabatic compression. This causes an increase in total heat, entropy and temperature without increasing the pressure.

If the compressor were water-jacketed this superheat could be removed at least in part. The work of compression for a given pressure difference would be decreased, thus increasing the efficiency of the compressor. The heat taken up by the water jacket is not available for evaporation, as it would be if allowed to remain as superheat in the compressed steam. Water-jacketing compressors is established practice in air compression. It might well be considered in connection with steam compression. In the following problems, however, the compressor is assumed to be not water-jacketed. Since the compressor is not 100 per cent efficient, compression is represented in Fig. 2 and Fig. 3 by the line BC' and not by BC.

Following are four problems representing hypothetical cases and are not to be taken as the conditions that actually exist but conditions that are assumed to exist.

Problem I

How much power is required to evaporate 10,000 lb. water per hour from a solution boiling at 212 deg. F., assuming heat losses by radiation, etc., are equal to the heat added in form of work to maintain the temperature difference of 18 deg. F.? Compressor and motor efficiency 60 per cent (based on adiabatic compression as 100 per cent).

***Solution*—A temperature of 230 deg. F. corresponds to a pressure of 20.77 lb. for dry and saturated steam. To**

find the total heat in a pound of steam which has been compressed adiabatically from 14.7 lb. to 20.77 lb., start on the Mollier (total heat-entropy) diagram at the intersection of the constant pressure line 14.7 lb. with the saturation curve and follow the constant entropy line vertically upward to the constant pressure line 20.77 lb. and read at the left of the diagram off the constant total heat line 1,177 B.t.u.

The power required is:

$$\frac{M(ic - ib)}{3420n} = \frac{10{,}000(1177.0 - 1150.4)}{3420 \times 0.60} = 129.5 \text{ kw.}$$

Problem II

From 12,000 lb. of solution fed to the evaporator per hour 10,000 lb. is evaporated. Boiling point is 212 deg. F., vapor dry and saturated. Liquor enters preheater at 60 deg. F. Condensed steam leaves preheater at 100 deg. F. Radiation 0.25 per cent (based on evaporation). Compressor efficiency 63 per cent (based on adiabatic compression as 100 per cent). Motor efficiency .95 per cent. Specific heat of solution leaving and entering is 1.

(a) What is the temperature difference?

(b) How much power is required?

(c) If the coefficient of heat transmission is 250 B.t.u. per hr. per deg. F. per sq.ft., how much heating surface is required in the evaporator?

Solution—To simplify calculations, use 60 deg. F. as a datum for calculating total heat entering and leaving machine.

Heat entering apparatus:

(a) Heat entering the apparatus as such equals 0, as the feed liquor enters at 60 deg. F.

Heat leaving apparatus:

(a) In condensate
10,000(100 − 60) 400,000 B.t.u.

(b) In thick liquor
2,000(212 − 60) = 304,000 B.t.u.

(c) By radiation
10,000 × 970.4 × 0.0025 24,260 B.t.u.

Total 728,260 B.t.u.

All of this 728,260 B.t.u. leaving the apparatus is added by the compressor in the form of work; therefore

$$\frac{728{,}260}{10{,}000} = 72.8 \text{ B.t.u. added to each pound of vapor by the compressor.}$$

1150.4 + 72.8 = 1223.2 B.t.u. total heat in 1 lb. of heating steam. If the compressor were 100 per cent efficient, use the figure 1223.2. Since the compressor is 63 per cent efficient, use 1150.4 + (72.8 × 0.63) = 1196.2. To find the pressure of the steam leaving the compressor enter the Mollier diagram at 1196.2 and move horizontally to right to a point on constant entropy line directly above the intersection of the saturation curve with the constant pressure line for 14.7 lb. This falls on the constant pressure line for 26.4 lb. The temperature corresponding to 26.4 lb. from steam tables is 243.1 deg. F. The temperature difference is 243.1 − 212 = 31.1 deg. F. Temperature differences are taken as the difference in temperature between dry and saturated steam at the pressure P_1 and the temperature of the boiling liquid. From steam tables steam at 26.4 lb. with a total heat of 1,223.2 B.t.u. is superheated 130 deg. F. The actual temperature of the steam is 243.1 + 130 = 373.1 deg. F.

(b) The power required is:

$$\frac{M(ic - ib)}{3420n} = \frac{10{,}000 \times (1196.2 - 1150.4)}{3420 \times 0.63 \times 0.95} = 229 \text{ kw.}$$

(c) The heating surface $= \frac{10{,}000 \times 1011.6}{250 \times 31.1} = 1300$ sq.ft.

Problem III

Conditions are the same as Problem II except vapor is wet. The qaulity is 99.

(a) From the Mollier diagram the total heat in a pound of vapor at 14.7 lb. and quality 99 is 1140.4. The total heat in 1 lb. of heating steam is 1140.7 + 72.8 = 1213.5 B.t.u.

If the compressor were 100 per cent efficient, use the figure 1213.5. Since the compressor is 63 per cent efficient, use 1,140.7 + (72.8 × 0.63) = 1,186.5. To find the pressure of the steam leaving the compressor, enter the Mollier diagram at 1,186.5 and move horizontally to the right to a point on the constant entropy line directly above the intersection of the constant quality 99 with the constant pressure line for 14.7 lb. This falls on the constant pressure line 26.8 lb. The temperature corresponding to 26.8 lb. from the steam tables is 244 deg. F. The temperature difference is 244 − 212 = 32 deg. F. From the steam tables steam at 26.8 lb. with a total heat of 1,213.5 B.t.u. is superheated 107 deg. F. The actual temperature of the steam is 244 + 107 = 351 deg. F.

(b) The power is the same as in Problem II.

(c) The heating surface $= \frac{10{,}000 \times 1001.1}{250 \times 32} = 1250$ sq.ft.

Problem IV

From 14,000 lb. of brine fed to an evaporator per hour 10,000 lb. of water is evaporated and 4,000 lb. of wet salt is drawn from the machine. Pressure in the vapor space is atmospheric. Elevation of boiling point is 15 deg. F., hence boiling point is 277 deg. F. Brine enters preheater at 60 deg. F. Condensed steam leaves preheater at 100 deg. F. Radiation 0.25 per cent (based on evaporation). Compressor efficiency 63 per cent. Motor efficiency 95 per cent. Specific heat of condensate taken as 1. Specific heat of wet salt taken as 0.30.

(a) What is the temperature difference?

(b) How much power is required?

(c) If the coefficient of heat transmission is 250, how much heating surface is required in the evaporator?

Solution—As in Problem II, use 60 deg. F. as a datum.

Heat entering apparatus:

(a) Heat entering apparatus as such equals 0, as brine enters at 60 deg. F.

Heat leaving apparatus:

(a) In condensate
10,000(100 − 60) = 400,000 B.t.u.

(b) In wet salt
4,000 × 0.3(227 − 60) = 200,400 B.t.u.

(c) By radiation
10,000 × 970.4 × 0.0025 = 24,260 B.t.u.

Total 624,660 B.t.u.

$$\frac{624{,}660}{10{,}000} = 62.5 \text{ B.t.u. added to each pound of vapor by the compressor.}$$

1150.4 + 62.5 = 1212.9 total heat in 1 lb. of heating steam. If the compressor were 100 per cent efficient, use the figure 1212.9. Since the compressor is 63 per cent efficient, use 1150.4 + (62.5 × 0.62) = 1189.8. Using the Mollier diagram as before, find the pressure of the steam leaving the compressor to be 24.4 lb. The temperature corresponding to 24.4 lb. is 238.7 deg. F. The temperature difference is 238.7 − 227.0 = 11.7 deg. F. From the steam tables, steam at 24.4 lb. with a total heat of 1212.9 B.t.u. is superheated 111 deg. F. The actual temperature of the steam is 238.7 + 111 = 349.7 deg. F.

(b) The power required is:

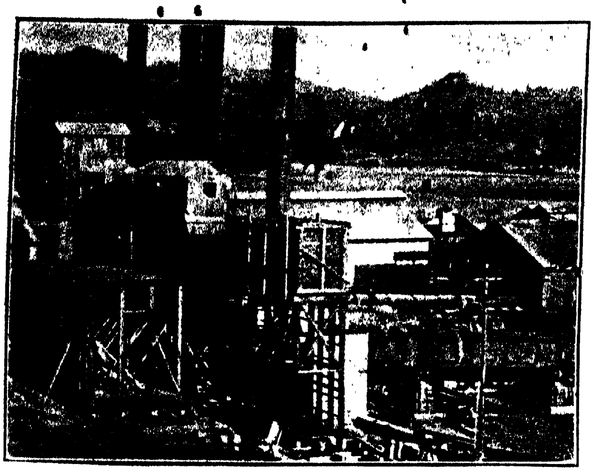
$$\frac{10{,}000 \times (1189.8 - 1150.4)}{3420 \times 0.63 \times 0.95} = 192.4 \text{ kw.}$$

(c) The heating surface is:

$$\frac{10{,}000 \times 1005.9}{250 \times 11.7} = 3340 \text{ sq.ft.}$$

Perils in Petroleum Production

At recent gatherings of oil men there was sounded a note of warning to the petroleum industry because of overproduction of crude and excessive stocks of gasoline. The members of the American Oil Men's Association have recently urged a vigorous buying movement by jobbers and distributors as a means of preventing imminent complete occupation of storage capacity. H. G. James, president of the Missouri Oil Men's Association, said that in some producing sections of the mid-continent field only 50 per cent of the companies' refining capacity is in operation and that many refiners were offering gasoline to jobbers at less than production cost. The cool weather is blamed for the condition.



Opening Up New Fields for an Industry

EDITORIAL STAFF REPORT

National Lime Association shows remarkable technical strength at its fifth convention. The development of quick-setting lime plaster, the manufacture of lime partition blocks and the extended use of lime in both asphalt and concrete roads are announced by the association's research organization.

THE National Lime Association sandwiched an open meeting between the executive sessions (which are open only to National Lime Association members) during its fifth annual convention in New York City, June 13 to 15. The effort was distinctly worth while. It gave a picture of the activities of the National Lime Association and of the excellent research work which is being carried out.

President Charles Warner presided, in the West Ball Room of the Hotel Commodore. In his opening remarks he pointed out that the Lime Association was not aiming to increase dividends this year or next year, but was working for the lime industry 10 years from now. The association can never be a trouble-shooter for the industry. It must have a long-time vision to be of any service. The president then introduced W. R. Phillips, general manager of the National Lime Association, who briefly outlined the work and the organization of the association. He enunciated the policy of the management of the association as being that of specializing in several of the most important problems and of making an intensive, rather than an extensive, survey. Naturally, all efforts cannot be confined along a few lines, but much better progress is made if problems are cleaned up and finished.

Four department reports were read by the men most closely associated with the various lines of activity. J. A. Slipher discussed the use of lime in agriculture. A survey of twenty states showed that, in spite of intensive campaigns on the part of universities and experiment stations, limestone has never been popular or widely used. Many reasons lie back of this unwillingness to adopt this material, the principal reasons being practical ones, in that the use of limestone does not fit in well with conditions of work on a farm. Mr. Slipher reported an increased use of burnt lime, pointing to a still greater use in time to come.

R. F. Brown discussed the work of the construction department, and interesting figures were read which showed an increase of 48 per cent in the tonnage of lime used in building in 1922 over 1921.

W. A. Freret took up the use of lime in highways—both in their construction, whether they be of asphalt or of concrete, and in the painting of objects along the side of the road and the borders on the roads, to make driving at night easier.

M. E. Holmes, chemical director of the association, outlined the activities of this department, including a brief résumé of the work done by the Fellows of the National Lime Association in the great institutions where these Fellows are located and by the central laboratory of the National Lime Association.

Following this, two papers were presented on manufacturing subjects. The first was by Oliver Bowles, mineral technologist, U. S. Bureau of Mines, and recently appointed head of the New Brunswick Experimental Station, which is to be devoted to non-metallic minerals. Mr. Bowles announced that one of the men at this laboratory would undoubtedly be placed principally on the utilization of limestone quarry waste.

Heat Losses in Limekilns

The second was by V. J. Azbe, on the heat loss in limekilns. A great deal of trouble in lime plants comes from the improper proportioning of fuel and air. CO_2 is a very significant figure in boiler gases, but it is even more significant in limekilns, for the percentage of CO_2 can be tied in very closely with the production of lime per ton of coal. For example, with 25 per cent CO_2 in the waste gases from the kilns a production of perhaps 3 tons of lime per ton of coal is indicated, whereas with 31 per cent CO_2 a 5 to 1 ratio is approached. Similarly, the loss of lime output can be determined by oxygen analysis, 2 per cent being about the optimum. An additional loss of heat, due to the withdrawal of hot lime, is accounted for and estimated from another chart, the temperature of the lime being variable and the amount of loss being due to the quantity of lime removed and the temperature. In addition to the losses already enumerated, there is an additional radiation loss which can also be estimated.

Lime Partition Blocks—A Remarkable Advance

The amazing story of the manufacture of lime partition blocks was told by Mr. Freret and W. E. Emley of the Bureau of Standards, illustrated with motion pictures of the machine in operation, taken in the plant of the International Clay Machinery Co., where the machines for manufacturing these blocks are being constructed. Investigation was started on March 3, 1923, and completed blocks were tested in the Bureau of Mines during April, so that the association can plead "guilty" of efficiency of the first order in conducting this interesting preliminary work. Thirty different types of blocks were manufactured, containing lime putty, lime hydrate, ground wood, wood shavings,

asbestos and other materials in widely varying proportions. The manufactured blocks will compete with gypsum blocks and with clay tile. In the test of the Bureau of Standards the lime blocks were found to be, in general, heavier than gypsum but lighter than clay, stronger than gypsum but again not as strong as clay, both in transverse and compressive strength. They have a greater absorption than clay but considerably less absorption than gypsum, and the permeability is so low that the block would probably have to be scored in order to hold plaster well.

Quick-Setting Lime Plaster

Perhaps the most dramatic story of all was that on quick-setting lime plaster. The investigation has been under way somewhat less than 6 months at the present time. What was wanted above everything else was a lime plaster that would set quickly and comparably with gypsum plaster. Lime plaster requires about 20 hours to set, whereas gypsum plaster sets in about 4 hours. The work was carried out along very comprehensive lines. One Fellow of the association working under R. T. Haslam at M.I.T. studied merely the compounds of lime, water and carbon dioxide. Another Fellow, under F. C. Mathers of Indiana University, undertook an Edison research to determine what materials, if any, would hasten the set of lime plaster. The third Fellow, under J. R. Withrow, of Ohio State University, studied the effect of burning conditions on time of set.

Professor Mathers' work met with a considerable measure of success, inasmuch as several methods of decreasing time of set were worked out. The first was by the addition of carbon dioxide to not over 5 per cent by weight. The second was by the addition of a water-soluble sulphate, ferric, magnesium and sodium sulphates being among the best. A mixture of 60 parts calcium oxide, 61 parts of water, 1 part of ferric sulphate and 3.6 per cent of carbon dioxide set in half an hour, as against 20 hours for a straight lime process. It is a simple matter to retard these quick-setting plasters as is done in the case of gypsum plasters, pure sugar being used in experimental work.

Professor Withrow reported that no relation between the time or temperature of burning and the set of lime plaster could be determined. Professor Haslam's report was an exceedingly interesting physical chemical study of the compounds that exist between calcium oxide and water, calcium oxide and carbon dioxide, and calcium oxide and carbon dioxide and water. Two general methods were adopted in carrying out this work. One was the study of a physical property of compounds or mixtures to see at what point a definite change of this particular property indicated a change in composition. The other method was to make the compounds themselves in several different ways, and then by analysis determine whether a new compound had been prepared.

Plotting data obtained from the literature on the solubility of lime, a transition point was noted at 60 deg. All attempts, however, to prepare a di-hydrate or a higher hydrate of lime failed, and on a redetermination of solubilities no transition point was noted. Also the vapor pressure plotted as the logarithm against the reciprocal of the temperature showed no breaks in the curve, indicating a single compound, the mono-hydrate. Similar results were obtained with calcium carbonate, only one compound being recognized. And, finally, the system CaO-H_2O-CO_2 was studied on both the acid and basic side of equilibrium and at absolute neutrality, three compounds being established.

Data on Quick-Setting Lime Plaster Summarized

In bringing together all the data related to the work on quick-setting lime plasters, G. J. Fink, research chemist of the association, stated that 2,000 mixtures had been investigated, using 220 addition agents in varying amounts and combinations. The tests made usually consisted of time of set, workability and tensile strength. Note was taken over the period of hardening, of shrinkage, water absorption, etc. The plaster was taken to be satisfactorily hardened when it showed a penetration of 2 cm. of the Gilmore needle.

The classes of substances tried out as addition agents include: oxides, with especial reference to those of lead and iron; oxidizing agents, such as calcium hypochlorite; acids; various siliceous materials, including infusorial earth, asbestos, etc.; greases and oils; and finally such unclassified materials as phenol compounds, sulphite waste liquor and carbon black.

Several materials were found to increase the strength of the plaster. Portland cement, calcined gypsum, cryolite and calcium chloride are included in this list. Carbonates in general impart the same property, while lead acetate affects plaster in this way to a remarkable degree.

The results with regard to those materials that reduce the time of set indicate that cement clinker, calcium aluminate, or a combined addition of inorganic sulphate with carbon dioxide, gives greatest promise in bringing about the effect desired. While a plaster containing 25 per cent of cement required 21 hours 35 minutes to set, the time was reduced to 5 minutes by the addition of $MgSO_4$ and CO_2 in relatively small proportion. In some cases the acceleration brought about was so great that the use of a retarder was found to be necessary. Gypsum or sugar in small quantities was found to be most satisfactory for this purpose.

The following combinations were suggested as being most likely to yield satisfactory results upon commercial development: Lime and calcined gypsum; lime and portland cement; lime and calcium aluminate; lime and cement clinker; hydrated lime and ground quicklime; lime and an inorganic sulphate (with the possible addition of CO_2); lime and a dry silicate; lime and an inorganic carbonate; lime and a soluble aluminate; lime and cryolite; lime and a substance containing tannin.

Lime in Agriculture

A bulletin, "Lime in Agriculture," has been prepared by the dominion chemist, Dr. F. T. Shutt, in response to many inquiries from Canadian farmers, respecting the application of lime and the relative merits of lime, ground limestone and other related substances. Dr. Schutt points out that there is a use and misuse of lime and that, unless rationally employed, the immediate advantages may be followed by decreased yields due to soil impoverishment. On the other hand, lime and carbonate of lime, if correctly used, are of much benefit, increasing crop production without impairing the soil's fertility. The author states that the exclusive and excessive use of the more caustic forms (quick and slaked lime) must inevitably lead to exhaustion of fertility, as they act as stimulants, setting free, but not adding to, the soil's store of plant food.

Abatement of Industrial Stenches by Means of Activated Carbon

A Review of Previous Efforts at Eliminating Industrial Stenches and a Description of an Installation Using Activated Carbon That Successfully Cured the Stench Nuisance in a Rendering Plant

By Arthur B. Ray and N. K. Chaney
Union Carbide & Carbon Research Laboratories, Inc., Long Island City, N. Y.

Industrial activity is egocentric and breeds forgetfulness and lack of consideration of the rights of others. Sometimes it becomes necessary for sluggish law to take a hand. So arose employers' liability and workmen's compensation. This other problem of industrial stenches has crept into that category too. Their economic elimination, whether on account of compulsion of law or as an expression of a more genial spirit, will be a great public gain. A technical problem that bears directly upon public happiness and comfort! This article discusses a suggested solution of wide application and great promise. It is a significant signpost.

THERE are many industrial processes which unavoidably give off objectionable odors or vapors. Many of us are familiar with the particularly obnoxious odors given off from the processes of rendering slaughter-house waste and other waste fats to recover tallow and have noted from time to time the publicity given to controversies between the health authorities and the operators of these processes. Other industries rather well known by reason of their odoriferous byproducts are the glue, fertilizer, soap, varnish and hide-treating industries. There are also numerous chemical plants which not only give out foul odors but in some cases more or less toxic vapors and gases.

In many cases, plants which give off particularly obnoxious odors and fumes are located in isolated sections as far away from habitation as possible. But obviously such an enforced isolation is rarely economical, so the operators of these plants have tried to satisfy the health authorities by various attempts at abating the nuisance.

Where these processes are operated and attempts are made to abate the nuisance, it is customary to cover or hood the containers and apparatus in which the processes are carried out, and by keeping a positive suction upon them by means of suction blowers to prevent the immediate dissemination of the objectionable odors and vapors. This protects the operators and persons in the immediate vicinity of the apparatus. The question then arises as to what disposal to make of the air laden with obnoxious fumes and vapors.

Various methods of disposing of this foul air have been suggested and tried. One of the simplest schemes is merely to pass the air into the tall stack from the boilers, the idea being that by mixing the foul air with the hot combustion gases from the boilers, some of the foul material will be destroyed and the rest disseminated in such a tenuous form as to cease to be a nuisance. Unfortunately, such a simple scheme does not satisfactorily solve the problem in the large majority of cases. Very little of the foul matter is destroyed in such a process and although the concentration is reduced, the nuisance is not abated, as many inhabitants of sections adjacent to rendering plants can and do testify vigorously. Putting the foul vapors into a stack really aids in their dissemination over wider areas.

Passing the air laden with foul matter through water sprays has been tried, but, except in certain cases where the objectionable matter such as acid fumes, etc., is readily soluble in water, this procedure is of practically no value. In some cases attempts have been made to mask or neutralize the foul odors given off from certain processes by injecting into the foul air a volatile material having a pleasant odor. Some of the volatile materials used are claimed to disinfect the air as well as mask the foul odors. In other cases, the foul air is passed over pots in which sulphur is burned or tar is boiled and thus is mixed with sulphur dioxide or tar fumes with the idea of reducing the obnoxiousness of the odor.

A recently developed process attempts to render the foul matters innocuous by causing them to react with chlorine. In the successful operation of this process, a careful adjustment of the proportion of chlorine and foul matter must be maintained, since either an insufficiency or an excess of chlorine is undesirable. It is obvious that such a process can be operated only under constant supervision. As a matter of fact, it was developed and intended to be employed in connection with large city garbage and waste disposal plants.

An Activated Carbon Installation That Proved Satisfactory

It is evident, therefore, that the methods discussed are either ineffective or too complicated for general use. If a rendering plant, for instance, could not by these known means cease to pollute the atmosphere with foul odors when ordered by the health authorities to do so, it had no alternative but to shut down. This was the situation exactly when we were asked by the officials of a rendering plant to devise some means that would permit the plant to operate without disseminating

Paper presented at the Wilmington, Del., meeting of the American Institute of Chemical Engineers, June 20-23, 1923.

the foul odors which had prompted the order to abate the nuisance or shut down.

It was an emergency, and we acted accordingly by hastily designing, with very little data to guide us, an installation which was rather crude from an engineering standpoint but which we thought would solve the problem. It did. The fumes and odors from the rendering kettles are caused to pass into a bed of activated carbon

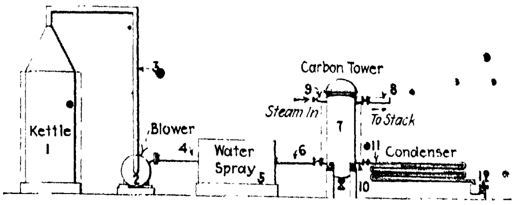


FIG. 1—DIAGRAMMATIC LAYOUT OF STENCH-ABATING INSTALLATION USING ACTIVATED CARBON

which absorbs them completely. When the carbon, after use for some time, becomes saturated with the impurities it is revivified *in situ* and used for another period.

After the erection of the installation in October, 1922, the plant officials and the town authorities expressed their perfect satisfaction with its operation.

Type of Activated Carbon Employed

The activated carbon successfully used in the installation is a granular, highly activated coconut charcoal of around 8 to 14 mesh. This carbon is the best for the purpose because (1) it has a high absorptive capacity for odors and vapors; (2) it selectively absorbs the organic and odoriferous substances in preference to water vapor; (3) it is mechanically strong and so resists crushing and abrading action; and (4) it is relatively dense so that a minimum volume has a maximum absorptive efficiency.

Operation of Installation

An elevation of the installation is shown in Fig. 1. Reference numeral 1 denotes a closed rendering kettle which is the source of the objectionable odors or fumes. Blower 2 draws the kettle fumes through pipe 3 and forces them through pipe 4 into chamber 5, where they are cooled by passage through a water spray. A draw-off pipe is provided at the bottom of this chamber and leads to a sewer. The cooled gases and fumes with or without drying then pass through pipe 6 to the purifying tower 7, which contains granular activated carbon. The gases from which all obnoxious matter has been removed by the activated carbon are then discharged in the air through pipe 8.

When it becomes necessary to revivify the carbon, it may be heated by any suitable means, but preferably by passing steam through it, to cause it to release the impurities it has taken up. In the installation shown, steam under 15 to 25 lb. pressure enters through pipe 9, passes downward through the carbon and out through pipe 10. The discharged steam is run to condenser 11 and the condensate trapped off into a sewer. Any uncondensed steam or other vapors and fixed gases are passed through pipe 12 into the firebox of the boiler used in generating steam for the plant or are otherwise readily burned under conditions to insure complete combustion. The revivified carbon is cooled by passing cold air or water through it and is then ready for re-use. If desired, the carbon may be dried by passing air through it while it is hot.

The details of construction of the carbon tower employed in the emergency installation are as follows: The cylindrical container of ¼-in. steel is provided with a horizontal partition in grid form in its lower portion. On the grid are placed a 4-mesh galvanized iron wire screen and a 20-mesh brass wire cloth to support the carbon. Similar screens are placed on top of the carbon to prevent particles of carbon from being carried upward by the ascending gas current. The top screens are weighted and freely movable so that they may follow the charge if it settles. Valves control the inlet and outlet of gases and are closed during the revivifying operation. Other valves control the inlet and outlet steam or hot water used in revivifying the carbon and are closed during the absorbing operation. A draw-off pipe with valve is also provided in the base of the tower. A 6-in. flanged pipe is provided for withdrawing the carbon at any time. The tower is jacketed with heat-insulating material to reduce radiation losses during revivifying operation. The tower as it appeared installed is shown in Fig. 2.

General Principles Applying to Any Installation

It is obvious that the dimensions and details of construction of the carbon container and the general arrangement of the apparatus may be varied to meet the needs of a particular installation. The amount of carbon used and the depth of layer may be varied. A number of small towers may be used in series or parallel. The foul air may be sucked through instead of blown through. The foul gases may be cooled by passing through coils externally cooled by air or water. If cooled by passage through a water scrubber, the gases may be dried by passage through a drying agent such as lime or calcium chloride. It is pointed out, however,

FIG. 2—ACTIVATED CARBON ABSORBER (CONTAINS 1,000 LB. OF GRADE 4 CARBON, 8-14 MESH)

that drying is not necessary, since the carbon selectively absorbs organic vapors and particles in preference to water vapor and will, therefore, effectively purify foul air which carries a large amount of water vapor.

The particular installation described was not designed for continuous operation, because the plant is not operated continuously. There is ample time at this plant for revivifying the carbon and getting it ready for re-use between the operating periods. However, if continuous operation is desired, the carbon tower may be duplicated and suitable connections and valves added so that one tower may be in operation while the carbon in the other is being revivified.

The length of time which the carbon may be in service before it becomes saturated with the foul substances and must be revivified will, of course, depend upon the amount of foul materials passed in per hour. The capacity of the carbon for absorbing and retaining the foul materials is very large. It will take up and retain more than 50 per cent of its weight of certain vapors. So, since the actual weight of foul materials in the air is usually very small, the carbon will remain effective for a considerable time. At the installation described, it has been the practice to revivify the carbon once a week, but the indications are that the carbon is not saturated by a week's use, and that the periods between revivifications could be longer.

No Attention Necessary

The installation requires no attention during operation. The only power required is that necessary for the operation of the suction blower which keeps a suction on the kettles, etc., and which forces the foul air through the bed of carbon. The resistance of the carbon to the passage of air is of course dependent upon the depth of bed and volume of air passed per sq.ft. per minute. It has been determined by actual plant operation that the pressure drop through a bed of 8 to 14-mesh carbon 5 ft. deep is approximately as follows:

2.25 lb. when 75 cu.ft. per sq.ft. is passed,
1.25 lb. when 50 cu.ft. per sq.ft. is passed, and
0.5 lb. when 25 cu.ft. per sq.ft. is passed

The passage of 150 cu.ft. of air per minute through a cylindrical bed of 8 to 14-mesh carbon 5 ft. deep and 3 ft. in diameter will require a pressure of around 0.5 lb. This rate is sufficient to keep a positive suction on several vats or kettles, for instance, and can be obtained by the use of a small Roots positive blower or other suitable blower.

The total cost of operation includes the cost of operating the pressure blower, supplying, if necessary, cooling water to cool the air and vapors before they enter the purifier, heating the carbon in the revivifying process by introducing steam or hot water or by other means, and cooling the carbon by passing cold air or water through it. Without going into details, it is obvious that the total operating cost is very small.

Conclusions

We have demonstrated that industrial stenches can be effectively abated by the use of a simple installation employing activated carbon as the absorbing medium. Highly activated granular coconut charcoal is the type of carbon successfully used. The original cost of the installation is not large and the operating cost is very small. The installation requires no attention except during the periodical revivification, which is carried out by simply heating the carbon *in situ* by steam or other means. The signal success of the installation now in operation leads us to believe that the principles employed in this case may be applied to solving similar problems at other plants and may be of real value to those industries which are so unfortunate as to have obnoxious fumes and odors for disposal. With such an installation available, there is no reason why any industrial process should be operated so as to pollute the atmosphere with foul odors.

The authors desire to express their appreciation of the engineering assistance given by H. D. Edwards, of the Linde Air Products Co.

Glass Wool Heat Insulation in Europe

Data on glass wool, a heat-insulating material practically unknown in this country but coming into intensive use in Europe, are given by A. D. Saborsky in an article in the May, 1923, *Journal of the American Ceramic Society*.

In the first machines developed for the manufacture of glass wool, the tips of a number of horizontal glass rods were melted by rotating them in gas flames and the drops thus formed were carried to the surface of a revolving drum upon which the threads of glass were wound. Breaks had to be renewed by an operator, of course, and the obvious improvement of supporting the rods vertically so that the threads would be self-renewing was delayed for a long time. The high cost of thin rods next directed efforts toward the use of scrap glass as raw material, and the present method is to melt scrap in a tank provided with a number of small openings in the bottom through which the glass flows to form threads which are wound up as before on drums. Drops are thrown off by centrifugal force so that only light wool accumulates on the drums. To insure steady flow, the openings may be heated with individual electric coils, or air pressure may be put above the molten mass. In a factory under construction in Dresden, Saxony, every furnace will feed three vats of 200 openings each. From present production figures it is estimated that about 6,500 lb. of wool will be produced in 24 hours. The help required would be two spinners, one melter and one helper per furnace, which would result in an output of almost 70 lb. per man-hour. The fuel consumption is 32 cu.ft. of artificial gas per pound of wool. Glass wool insulation is selling for 12c. per pound and the writer estimates the manufacturing cost at about 2½ to 3½c. per pound.

The product is cut off the drums, carded and loosened up by hand. It weighs about 13.8 lb. per cu.ft. as against an average of 156 lb. for solid glass, so that it contains approximately 90 per cent dead air cells by volume. It may be exposed to temperatures far above the melting point of the glass when used in insulating very hot pipes—for example, the exhaust pipes of heavy oil engines—and the only effect will be the baking or melting of a ⅛- or ¼-in. layer directly in contact with the heated surfaces, the rest of the wool being unaffected.

Glass wool may be applied in several forms, the most common being bands ⅜ to ½-in. thick and 2 to 10 in. wide. Larger pipe line and other objects are often insulated by first surrounding them with coarse wire mesh in a position representing the outline of the finished insulation. The space between is then simply stuffed with the wool. For locomotives, boilers, etc., where the insulation has to be removed periodically, mattresses are formed between two templets of fine wire mesh

Co-ordinating Colloid Data

First National Symposium on Colloid Chemistry at University of Wisconsin Affords Opportunity for Interchange of Views

FROM MANY ANGLES, the Symposium on Colloid Chemistry held under the auspices of the University of Wisconsin at Madison June 12 to 15 was unique among scientific gatherings in this country. Forces of attraction brought into play by the interest taken in colloid chemistry at Wisconsin and the presence of Professor Svedberg drew together more than a hundred enthusiasts normally dispersed throughout the country. For 4 days the theories and facts of colloids were discussed without interruption. Papers for the program had been carefully chosen and ample time was given for presentation and discussion, points that contributed in no small measure to the great success of the meeting. Papers were limited to 40 minutes, but discussion was unlimited and in many cases exceeded the time of presentation. It was recognized that one of the most valuable features of such a gathering lies in the free exchange of views among men of varied experience. The symposium attracted engineers and biologists as well as men interested in plastics and in agriculture, and the important thing is that each was able to help the other. In addition, there were the stimulating criticisms and suggestions by Professor Svedberg.

The University of Wisconsin is planning to publish the papers and all the discussions as a special monograph, copies of which may be reserved by notifying Prof. J. H. Mathews, chairman of the department of chemistry, University of Wisconsin. Further recognition of the important start made by Wisconsin is to be found in the decision of the colloid committee of the National Research Council to hold a second symposium next June at Northwestern University.

From what has been said it should not be inferred that the weighty deliberations precluded social features. Madison affords most delightful natural surroundings for such a gathering and the Wisconsin hosts provided an automobile excursion, launch ride, picnic supper and other entertainment. The total attendance was about 250.

Turning to the technical program, this was opened by Professor Birge of Wisconsin, who expressed the hope that through such meetings it might be possible to co-ordinate and simplify the facts of science, which are increasing at such a rapid rate. The papers presented are given in abstract in the following paragraphs:

Properties of Sols and Gels

Studying the thermochemistry of sulphur sols, F. L. Browne found that the heat effects of coagulation of colloids are due to interaction of ions, not to energy changes accompanying the changes of aggregation. Accurate measurements were made with an adiabatic calorimeter with NaCl, KCl, $MgCl_2$ and $AlCl_3$. They are particularly interesting because they are reversible With NaCl a greater heat was observed on partia coagulation than on complete coagulation. With AlCl no heat was evolved on coagulation for either large or small particles.

A study of precipitation of sols by alcohol led Prof W. D. Bancroft to suggest that our values for the singl potentials of metals may be in error by as much as 0.7 v in certain cases. Dr. Bancroft and J. B. Nichols als noted that camphor peptizes pyroxylin and has no effec upon its freezing point unless water is present.

H. N. Holmes advanced the "brush heap" structur for gels. An analogy is the "false gel" found by th crystallization of 4 per cent caffein from water, givin a mass of interlocking crystals and water which can b inverted without flow of the liquid. The fibrous stru ture of cotton still exists in guncotton and can b observed by precipitation with alcohol. Various meth ods of making gels were illustrated. A new silica ge precipitated by nickel chloride was found to adsorb 10 per cent of its weight of benzene vapor. This pape was followed by an experience meeting on gels. Late in the week H. B. Weiser outlined the factors influ encing the formation of inorganic jellies. Coagulatio

at proper rate was found to be important, although the H-ion concentration was not. In the majority of cases it is beneficial to mix cold and then raise the temperature.

Demonstration of Colloid Technique

Recent advances in colloid chemistry have been made possible by improved apparatus and technique, factors that were demonstrated Tuesday afternoon by Prof. The Svedberg. The ultra-microscope, sedimentation and deposition of gold on small colloid particles as nuclei are used in determining particle size. Distribution curves are established by the sedimentation balance and by photography. Shape is studied by X-ray methods and by polarized light. The charge on proteins is determined by cataphoresis experiments, using their fluorescence in ultra-violet light to follow the moving particles. A recent improvement in electrical methods for preparing colloids consists in inclosing the arc in a quartz tube and blowing through nitrogen. Professor Svedberg's apparatus was shown on slides and after the meetings his researches at the university were described in the laboratories.

> **In any field where a large number of workers are pursuing various lines of endeavor, nothing is more conducive to real progress than an occasional opportunity for free exchange of ideas. Such an opportunity was afforded those interested in colloid chemistry by the symposium on this subject held under the auspices of the University of Wisconsin and the results have so far exceeded even the most optimistic expectations that a second symposium has been arranged for next year. Accordingly, we may predict a rapid yet co-ordinated development of colloid chemistry in this country, a development which will reflect great credit upon the forward-looking originators of this plan.**

Problems of adsorption from the standpoint of catalysis were considered by Prof. H. S. Taylor. The heat of adsorption of hydrogen on nickel is calculated to be 13,000 calories, a value which agrees with calorimetric measurements. Since the heat of vaporization is 450 calories, something more drastic than liquefaction must occur during adsorption.

R. E. Wilson called attention to the importance in lubrication work of studies on solutions which give abnormal surface tensions and whose surface films may be considered as plastic solids.

It was pointed out by E. F. Burton that the Helmholtz double layer is not applicable to colloid systems in general, since the particles are charged and do not come in contact with one another. For concentrated colloid systems the calculation of Avogadro's number is not valid, because the particles exert a force on one another which is not considered in the equation. Charges are neutralized and Brownian movement slowed down before coagulation.

A new theory of emulsification was enunciated by Prof. J. Hildebrand. Emulsifying agents form a monomolecular layer at the interface with the polar part in the water and the non-polar part in the oil. The relative atomic volumes of the two parts determine the radius of curvature, which in turn determines whether the water or the oil is to function as the dispersed phase.

Lively Discussion on Protein Behavior

Thursday's program on protein behavior and allied subjects brought out some lively discussion, particularly that on the ionic theory which followed J. A. Wilson's review of the applications of the Donnan equilibrium. Other papers included were those of Dr. J. Loeb, on the relation between various properties and the H-ion concentration; J. H. Mathews and B. W. Rowland, on calorimetric studies to determine whether protein behavior on the addition of electrolytes is due to chemical action or adsorption; M. H. Fischer, on the theory of lyophilic colloids; David Klein, on the conditions necessary for the commercial production of enzymic and animal glandular products; I. I. Ostromuislenskii, on the relation of colloid chemistry, particularly adsorption, to medical therapy; A. W. Thomas and Lucille Johnson, on mutual precipitation which is caused by chemical reactions between ions adsorbed on the surfaces of the oppositely charged particles. R. H. Bogue discussed the conditions affecting the hydrolysis of collagen to gelatine. Digestion of various hides at different temperatures and different p_H values, followed by analysis for free amino groups throws light on the mechanism.

Of the papers presented on Friday, that of Jerome Alexander is already familiar to our readers through the series of articles on the "Colloidal State in Metals and Alloys" published in *Chem. & Met.* from Jan. 11 to Feb. 1, 1922. E. B. Spear discussed the many phases of the rubber colloid system, the influence of compounding ingredients on physical properties and milling studies made possible through rapid acceleration at low temperatures.

Experiments on photographic behavior were reported by S. E. Sheppard. Photographic emulsions of identical grain distribution behave differently. Svedberg's method of determining the percentage of developable grains has been of great service in this field. The development nuclei are scattered at random and it is important to know whether or not they exist prior to exposure, and if so, whether they are all of equal sensitivity. Apparently the nuclei are colloid particles distributed through the halide crystal rather than crystals distributed through the colloid gel. It is impossible to distinguish between the classical theory and the quantum of light from these experiments.

Agricultural applications were considered by R. Bradfield and R. A. Gortner.

Hardness of Very Hard Steel

An attempt has been made by the Bureau of Standards for the past 3 or 4 years to obtain a very hard steel ball which will carry the load of 3,000 kg. in a Brinell testing machine when working on very hard metal, but up to the present without success. Tungsten carbide has been suggested, but it has been impossible to obtain this material in suitable condition in either this country or Germany. Recently a very hard vanadium steel made at the bureau's laboratories has been tried and shows promise of success.

Steel Treaters Meet at Bethlehem

Regional Meeting Well Attended—Toughness of Steel Measured at Normal and Low Temperatures—Cracking and Bursting of Steel Tools Thoroughly Discussed—Comprehensive Study of Case-Hardening Practice

EDITORIAL STAFF REPORT

ANOTHER very interesting and successful meeting was held by the American Society for Steel Treating, at Bethlehem, Pa., June 14 and 15. Participating in this gathering were all the local organizations in the Eastern states, which sent about 100 of their members to enjoy the technical sessions and the inspection of the Bethlehem Steel plant. Five important papers were presented and discussed; space limitations permit us to summarize but three of these.

BRITTLENESS OF COLD METAL

Dr. F. C. Langenberg and his co-workers at the Watertown Arsenal have been engaged in a lengthy investigation of the impact strength of several steels, when tested at temperatures ranging from 80 deg. below zero, F., to 1,000 deg. He presented an account of this investigation as far as it compared the impact strength of steel at normal and cold temperatures. This is a matter of considerable importance. The behavior of rail steel and railroad axles in very cold weather has been exhaustively studied, but it is seldom realized that motor cars or trucks may be called upon to resist heavy shocks in the coldest weather, or that airplanes may hop off on a hot summer day and rapidly mount to a sub-arctic temperature.

A large Charpy impact testing machine was used. Specimens 3 cm. square with the usual round-bottomed notch were broken. Temperatures from 0 deg. to 50 deg. F. were obtained by working with windows open in winter; lower temperatures were had by immersing the sample in an acetone bath, to which CO_2 snow was added. When the specimen had maintained the desired temperature for some time, it was withdrawn quickly and tested; the operation required about 10 seconds, and the temperature of the specimen changed no more than ½ deg. F. during that time.

In general it is found that the impact resistance of steels, both annealed and heat-treated, is very low at low temperatures. With rising temperature, however, there comes a range when the toughness increases very rapidly, and at 200 deg. C. most of the steels that were heat-treated attain their maximum toughness. Annealing generally increases the brittleness at low temperatures, and the piece has small toughness until tested at a materially higher temperature than the same steel when heat-treated. This is only another demonstration that alloy steels should not be used except in the heat-treated condition. Or, said in another way, coarse-grained, banded ferrite will give considerably lower impact than finely disseminated ferrite.

A nickel-chromium steel (S.A.E. 3220) and a carbon steel (S.A.E. 1020) used for case-hardened parts and heat-treated to give the conditions existing in a toughened core, are compared as follows:

Temperature Deg. F.	Steels No. S.A.E. 3220	Steels No. S.A.E. 1020
—60	420	273
—40	450	400
0	470	800
+50	590	960
110	650	1,030

The alloy steel has higher impact resistance at low temperature, but the relation reverses at summer heat (although the carbon steel gave very erratic results under test). The alloy steel is varying in toughness at a rapid rate at room temperatures, so it is necessary to control this item in routine tests if they are to be consistent.

Medium carbon 3½ per cent nickel steel (S.A.E. 2335) and chromium-nickel steel (S.A.E. 3240) have quite similar impact properties when heat-treated; the latter, however, registers 230 ft.-lb. at —80 deg. F., considerably higher than the gun steel.

WHY DID IT CRACK?

A discussion of that ever-present question "Why did it crack?" was presented by F. R. Palmer of the Carpenter Steel Co. in his paper, "Equalization of Internal and External Strains in Tool Steel." Starting from the evident proposition that a steel cracks when the total of the internal and external strains exceeds the strength inherent to that piece of steel, he showed how many occurrences during manufacture of a tool cause cumulative internal stresses of unsuspected magnitude.

First, the steel may be defective when it leaves the maker—containing either internal bursts, pipe or segregated impurities. Such occurrences have happened. The chief danger here is the "internal notching" effect, which causes concentrations of stress in the region of the defect many times the average across the entire section. Such defects can be made apparent by cutting off a slab and pickling it in 1:1 HCl.

Second, even the best steel can be destroyed by a poor designer. Especially should he avoid sharp corners at the root of notches and keyways. Re-entrant angles and unbalanced sections (heavy masses adjoining light wings) are sometimes necessary, but then the designer must make every effort to relieve the stresses by proper proportioning of adjacent parts.

Third, the act of machining puts strains into the surface layers of the steel, especially if the cutting tool is not in first-class condition or is overworked.

These three effects may be cumulative and at times will crack the tool before it gets to the hardening bath. But if any tool is the least suspicious, it should be carefully annealed to relieve the internal stress as much as possible, so as to enter the hardening furnace in the best possible shape.

Hardening practice unavoidably introduces very severe strains in the metal. To minimize the danger, heating should be slow and uniform so the entire tool will expand at the same rate; special care should be exercised when passing the critical range, where a sharp contraction in volume occurs. In quenching it is obvious that heavy thermal and transformational stresses must occur, and it should be apparent that the steel must be in the best condition to withstand the punishment if disaster is to be averted.

When judging temperatures by eye, the tendency is

to overheat the steel. With pyrometric control, the operator is more often likely to withdraw the piece before it is hot enough. Water-quenched tools, cracked after underheating, have a quite characteristic appearance: the corners shell off and the piece parts along a surface which apparently was at equal temperature. The shelled-off corners are file-hard with good fracture, smooth and fine grained; the core, however, never having been through the critical range, is coarse grained and soft.

Appearances of cracked oil-hardened tools are somewhat different. If the steel is defective, the crack usually runs along the bar, following a segregated streak. If cracking is due to poor design, the cracks are regularly found in certain places and have regular directions and similar depths. If the tool shatters into a number of fragments it is usually a poorly hardened tool, reheated at too rapid a rate. Such a failure is an exaggerated grinding crack. The cracks originate during heating and oxidize, then split further during quenching. Such ruptured surfaces are partly oxidized, partly clean.

But suppose the tool to withstand successfully the quenching operation; it is obvious that the drawing operation should immediately proceed to remove as much of the internal strain as possible without removing any more of the hardness than necessary. A long, low draw is the way to effect this desired end. The maximum amount of softening caused by a tempering heat occurs in 15 minutes; it takes 5 hours or more to relieve quenching strains—draws of indefinite length do not damage the quality of the piece.

If any straightening is done, it should be done immediately after the drawing operation, while the metal is still warm. Any damage to the elastic properties caused by the overstrain of a straightening press will then correct itself while the metal is cooling. If cold straightening must be done, the damage to the elastic properties may be cured by a short stay in boiling water.

Finally, a perfectly sound tool may be cracked during grinding. Here Mr. Palmer distinguished two types of troubles, grinding checks and grinding cracks. Checks are only a few thousandths deep and are caused by too rapid grinding or rubbing against a dirty, dull wheel. (Wheels are rapidly fouled if they are working on pieces the skin of which has been decarbonized during heat-treatment.) Grinding cracks, however, are much deeper, and represent the deepened check which opens up in a badly strained tool.

Study of Carburizing

An exhaustive study of the carburizing process was presented by B. F. Shepherd, of the Ingersoll-Rand Co. Since a considerable portion of their carburized work goes into air hammers and drills where it must resist not only wear but very violent and repeated shocks, it is clear that their metallurgists must be able to control that hardening operation within close limits. Their general practice is to avoid the use of carbonized pieces if the part can be made satisfactorily of heat-treated alloy steel, despite the fact that it may be cheaper to machine the softer steel, carbonize and harden. Since carbonizing is a process that may be expected to magnify any defect in the original steel, it is good practice to keep the number of analyses at the minimum, obtain from the manufacturer whose metal gives greatest uniformity, and to inspect rigidly upon receipt of shipments.

Several different steels of first quality and analyses usually put into carburized work were studied by Mr. Shepherd, varying the type of cement, the time and the temperature. Carbon penetration was determined by analyzing successive shells, carefully machined from the surface. Most of the samples were carbonized 24 hours at 1,600 deg. F. The results were presented in a series of diagrams, and only the most general conclusions can be noted here.

Properties Which Should Influence Selection of Carbonizers

In general, it may be stated that a light compound and one which does not settle when packed is desirable, since it is sold by weight but used by volume. During heat, the compound should shrink very little, and quite uniformly. To avoid discomfort to workers and clogging small openings in the metallic pieces, the material should be reasonably free from dust. It should not be too heavily "energized," since such a compound will damage the finish of machined steel. Its thermal conductivity is always low, but the higher it is the less time is required to bring the work to heat.

Home-made carbonizers of wood charcoal and $BaCO_3$ are not to be recommended for miscellaneous work. Their shrinkage is high, they pack badly, and are very dusty and dirty. If they must be used, it will be found that a mixture with 40 per cent carbonate gives no better results than a much lower proportion.

Service is the real test of carbonized work; routine tests are quite indirect. Samples from each heat should be broken in a standardized manner and the depth of case and refinement of grain noted. Files and scleroscope may be used to test the hardness—the standard Brinell requires too much metal to be applicable to carburized work. Sclerscope tests are usually quite high until the carbon drops to 0.50 per cent. File tests vary with the files, the method of testing, and the operator, but notwithstanding this, file testing is the usual method.

Soft spots on hardened carburized pieces may be due to many causes. In good work on first-class metal they are quite rare. Mr. Shepherd said they had observed a few examples of the "abnormal structure" of carburized, unhardened metal, described by E. W. Ehn, of Timken Roller Bearing Co. and blamed upon oxidized metal. However, such abnormal structures as had been found at the Ingersoll-Rand plant hardened perfectly and uniformly.

Testing of Molding Sand

In the issue of *Chem. & Met.* for May 14, 1923, page 860, a report of the Foundrymen's meeting at Cleveland contained some misinformation on the testing of molding sand. It is reported that R. E. Kennedy of the University of Illinois reported these tests to the meeting, but as a matter of fact the gentleman who spoke was H. B. Hanley, chairman of the subcommittee on tests. Furthermore, the quoted dimensions of the molding box are in error. Mr. Kennedy informs us that the box finally recommended by the testing committee is designed to give a bar 2 in. wide and 16½ in. long, while the height varies according to the amount the sand compresses after uniform ramming.

What Is the Future of the Mixed Fertilizer?

Use of High-Analysis Mixtures Held to Be Sound Policy in General Farming and a Most Effective Supplementary Means of Increasing Crop Yields*

BY FIRMAN E. BEAR†
Agronomist

THERE is rather general agreement among those who have given consideration to national problems that increases in the acre yields of crops are essential to our welfare. That the use of a well-chosen mixed fertilizer will result in a marked increase in the productive capacity of almost any soil which has been under cultivation for 25 years or more has been amply demonstrated by experiment station tests. Even in Liebig's day the effects from the use of his chemical manures "excited the wonder of all who passed by." That the manure, clover, limestone and phosphate program can be made equally effective is not questioned. The fundamental error in many men's conception of the problem of unproductive soils lies in their assumption that its solution lies in the adoption of some *one* system of soil management. Undoubtedly it lies in the supplemental use of *several* systems, sometimes more of one, at other times more of another.

MEASURING FERTILIZER EFFECTIVENESS

A complete fertilizer is usually more effective in increasing crop yields than is acid phosphate or any other single ingredient of the fertilizer when used alone. This is rather generally accepted as a fact and is supported by a large amount of experimental and circumstantial evidence. Choosing an example from the long-continued and carefully conducted field tests on the experimental farm at Wooster, Ohio, the following data are presented as being of interest in this connection:

EFFECT OF FERTILIZERS ON CROP YIELDS—WOOSTER SILT LOAM SOIL

Rotation—Corn, Oats, Wheat, Clover, Timothy.
Twenty-five Year Average Acre Yields, 1894-1918.

Fertilizer Per Rotation	Lb.	Corn, Bu	Oats, Bu.	Wheat, Bu.	Clover, Cwt.	Timothy, Cwt.
None	0	28.0	32.0	11.4	16.3	25.4
Acid phosphate	320	35.5	42.0	19.6	22.3	30.6
Muriate of potash	260	33.2	35.4	12.6	19.4	27.9
Nitrate of soda	480	33.2	36.1	13.3	20.8	29.6
Phosphate-potash	580	43.7	44.9	20.9	25.9	30.7
Complete fertilizer	1,060	46.8	51.2	28.1	29.8	34.5

It is not a difficult matter to find objections to such a type of experimentation if its purpose is that of determining directly what the fertilizer practice should be. On the other hand, it is difficult to decide upon some scheme of field experimentation that will satisfy the requirements when one takes into consideration the fact that the economic factors involved are constantly changing. If the cost of each ingredient in the complete fertilizer continued to bear a constant ratio to the total cost of the fertilizer and if the selling prices of crops remain the same, the problem would be relatively simple. Yet even then it would be necessary to have in mind that if the productivity of the soil is increasing as a result of the fertilizer treatment the analysis that gave the best return per acre when the test was initiated would not be likely to be the one that would be the most effective 10 years later. The very exactness with which the experimental field test is repeated each year defeats in part the purpose for which it is ordinarily intended. The soil is dynamic and not static.

FLEXIBLE FERTILIZER PRACTICE

Having these points in mind, it seems desirable to examine somewhat carefully another type of field comparison of fertilizers in which the quantities and analyses applied are more in keeping with what experimental as well as circumstantial evidence indicates to be good fertilizer practice. Such a comparison is also available at Wooster, having been begun after some years of study of the results obtained from the tests previously mentioned. The data follow:

COMPARISON OF EFFECTIVENESS OF VARIOUS FERTILIZER ANALYSES

Corn, Oats, Wheat, Clover Rotation—Wooster Silt Loam Soil.
Eight-Year Average Acre Increases From 1,000 Lb. of Fertilizer.*

Analysis	Corn, Bu.	Oats, Bu.	Wheat, Bu.	Clover, Cwt.
0-16-0	9.2	2.5	7.2	8.1
0-12-4	10.0	6.5	7.7	8.3
2-8-2	11.0	2.4	11.6	4.7
2-12-2	12.9	4.8	13.6	8.6
4-8-4	13.1	4.1	12.7	7.9
Unfertilized yield	55.3	51.5	24.0	39.7

* Fertilizer applied half on corn and half on wheat

The soil was in a fairly high state of productivity, as indicated by the average yields on the unfertilized plots. The rotation included clover once in 4 years and enough limestone was applied to prevent its lack from being a limited factor for this crop. Comparisons were made among equal weights of the several analyses used in the tests. In almost every case the mixed fertilizers produced larger increases than the acid phosphate alone. Of the list employed, the most effective analysis seemed to be the 2-12-2.

The thing that impresses one most in the Wooster data is the fact that the increases in yield with the 2-12-2 fertilizer were so much larger than they were when the acid phosphate was used alone. Does it not seem remarkable that one can take 4 per cent of phosphoric acid out of a fertilizer, substitute for it an equal percentage of ammonia and potash and raise the increase in yield of corn 40, of oats 92, of wheat 89 and of clover 36 per cent? Figuring these increases on the basis of weighted averages according to the Dec. 1 farm prices for the period 1912-21, the increase for the rotation from the use of the 2-12-2 over the acid phosphate alone is 63 per cent.

It might be argued that the conditions of the test were not fair. The clover crop was not plowed under; no manure was applied. With reference to the former it is my opinion that the plowing under of clover at any

*From a paper presented before the meeting of the National Fertilizer Association at White Sulphur Springs, W. Va., June 12-14, 1923.

†Professor of Agriculture, Ohio State University, Columbus, Ohio.

place east of the Mississippi River, and before long even west of it, is not good business. What is the logic of growing a crop to plow under except as this is made necessary in intensive systems of farming where livestock cannot be kept? With reference to manure requirements for high yields should be satisfied with acid phosphate, limestone and the frequent growth of legumes. But supposing the field hasn't had manure! It is now time to plant corn or sow wheat! Shall we suggest the use of acid phosphate or of a well-chosen mixed fertilizer?

The low state of productivity of a considerable percentage of the land east of the Mississippi River is due to certain economic conditions which have obtained over which farmers have had no control. As a result of the demoralizing effect of the Civil War the farmers of the South have had more or less of a hand-to-mouth existence. Meanwhile farmers in the Eastern states have found themselves in competition with millions of acres of virgin farm land in the West which are being exploited for their resources. As a result of these conditions we are approaching what may be termed a "national soil emergency condition." In overcoming this emergency condition complete fertilizers rightly used have been found to be a valuable aid. By the time their use for this purpose is no longer required, the more intensive systems of farming now practiced in the Eastern states will have spread over most of the area east of the Mississippi River and the need for complete fertilizers will be greater than ever.

There is nothing fundamentally wrong with the practice of using high-analysis mixed fertilizers. Every one of the analyses included in the Ohio Standard Dozen and in the similar lists suggested by agronomists of other states will be found to be a good investment on most of the land which has been under cultivation for 25 years or more. Fertilizers are not intended to take the place of manure and clover on a livestock farm. But as long as they can be used with additional acre profit, why not use them? The mere fact that they have been misused cannot be construed as any very legitimate argument against the mixed fertilizer.

The arguments against the 2-8-2 and other low grades as well as low-percentage analyses no longer apply. No intelligent farmer need buy anything but high-analysis fertilizers, made up of materials of known availability. If the farmer desires or should move in the direction of more intensive livestock farming and a bigger and better manure program, why not suggest that he may be able to "arrive" more quickly by the use of a complete fertilizer? Of course a 2-12-2 will not supply an adequate amount of nitrogen to satisfy alone the needs of large yields of crops, but if by its use the farmer can get a greater acre profit, leave a larger amount of crop residue in and on the soil and at the same time produce more manure to return to the soil, why shouldn't he use it?

The question might be raised as to whether we have any guarantee that the 2-12-2 on the market will duplicate in its effect the 2-12-2 of the experiment stations. There is still abundant opportunity for manufacturers to use organic ammoniates of low availability in their 2-12-2 and lower analyses. However, each year finds more of the control chemists "checking up" the availability of this organic nitrogen. If the National Fertilizer Association desires to rid itself of a large share of the criticism that still is directed against complete fertilizers, we commend for its consideration the following proposal regarding the nitrogen in mixed fertilizers which might well be embodied in a resolution to be presented to the Association of Official Agricultural Chemists at its next annual convention:

> The active water insoluble nitrogen *found* must be equal to or greater than the inactive water insoluble nitrogen *found*, as determined by the alkaline permanganate method of the A.O.A.C., unless the percentage of water-soluble nitrogen is equal to 70 per cent or more of the total *guaranteed* if the fertilizer is to be *passed.*

Fortunately the ratio of the organic to the total ammoniates decreases with the increased consumption of fertilizers. Furthermore, a larger percentage of the organic carriers are being acidulated. There is reason to believe that acidulated ammoniates contain their nitrogen in as available a form as that of dried blood or perhaps sulphate of ammonia. The comparison of the commercial 2-12-2 and the experiment station 2-12-2 is reduced therefore largely to a comparison of sulphate of ammonia and nitrate of soda as carriers of nitrogen.

The opinion, based on the experimental work of Wagner, later supplemented by that of Wheeler and Hartwell, is that sulphate of ammonia has an availability on limed soil of 90 as compared to 100 for nitrate of soda. Comparative trials on the Ohio Experiment Station farm at Wooster, on limed soil, the data for which are given below, indicate for sulphate of ammonia as a relative effectiveness of 70 on corn, 53 on oats, 80 on wheat and a residual effect of 69 on clover and 55 on timothy as compared to 100 in each case for nitrate of soda. The weighted average for these crops based on relative Dec. 1 prices for the years 1912-21 would be about 70.

COMPARATIVE EFFECTIVENESS OF VARIOUS CARRIERS OF NITROGEN

Soil Limed and Treated With Phosphate-Potash Mixture*
Increase from Nitrogen Calculated on Basis of Nitrate of Soda at 100

Carriers of Nitrogen	Corn	Oats	Wheat	Clover	Timothy
Nitrate of soda..........	100	100	100	100	100
Oil meal.......	69	61	43	27	31
Dried blood	61	44	49	41	19
Sulphate of ammonia	70	53	80	60	55

* The analysis of the mixture after the addition of the carrier of nitrogen was approximately 4½-7-13. This was applied at the rate of 980 lb. per acre per rotation and distributed among the first three crops.

We must admit that the substitution of sulphate of ammonia and of organic ammoniates for nitrate of soda in a fertilizer tends toward a reduction in efficiency. This is true at the rates in which fertilizers are applied in general farming. It may not be true when large amounts are used, but probably in the latter case applications of the most available carriers of nitrogen from time to time through the season rather than in one initial application are to be preferred. On the other hand, it must be kept in mind that the farmer has a much better opportunity to make a profit from the use of fertilizers than the experiment station data indicate. An important reason for this is that he can vary his fertilizer from year to year or from crop to crop to fit the need, a thing which cannot be done in the fertilizer tests.

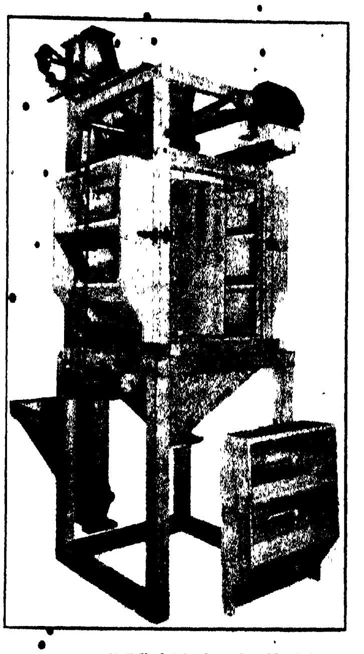
Materials and Accessories for Chemical Industries

New Bolting Reel

A machine that will sift finely powdered materials through a fine mesh, will at the same time aërate them, will prevent separation of the lighter and heavier ingredients and has a continuous large capacity is presented in the new vertical bolting reel made by the J. H. Day Co., Cincinnati, Ohio.

This reel has a vertical cylindrical bolting drum, inside of which are placed a series of disks and a fan. The shaft revolves at 1,200 r.p.m. The feeder, which is on top of the machine, allows the material to fall evenly upon these disks and the air current created by the fan blows the material through the screen.

A brush is caused to revolve inside of the screen against the surface of the mesh, thereby keeping it free from an accumulation of material. Around the screen is an expansion chamber inclosed by four doors. These doors are covered with muslin, which permits part of the air to pass out but retains the sifted material. This material slides down inclined surfaces on the doors and falls into the hopper below the screen. The majority of the screened material falls directly into the hopper. On the bottom of the hopper is placed a cylinder which acts in two capacities—one half of this cylinder is used to catch the dust from the air circulation between the outside of the sifter drum and inside and is connected to a cylindrical dust collector at the bottom, which has a spiral conveyor in the middle. All air passing through this drum and against the baffles in it deposits the dust in suspension, and it is conveyed to the discharge hopper. The material which falls to the middle of the cylindrical chamber, however, is carried by a conveyor running in the opposite direction to the tailing discharge. The air that passes through the muslin in the doors is replaced by air coming in through the intake, thereby reclaiming as much as possible of the material in suspension. A can or other container may be placed under the discharge valve and the sifted material removed from the hopper, if desired. This connection can vary, depending upon the installation requirements.



THE DAY VERTICAL BOLTING REEL

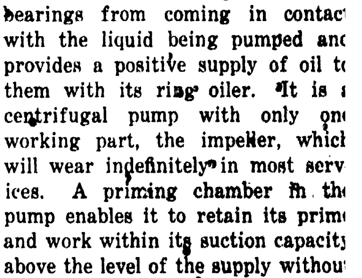
From the above description it can be seen that within the walls of this machine is a complete unit, capable of automatically feeding material into the sifter, accumulating all of the sifted material in the hopper, and discharging the material into a container. The advantages of this machine lie in the fact that the material is passed through the screen by the action of an air fan instead of by the ordinary method of gravity or vibration. The material is given a gyratory motion and is blown through the screen, which is stationary, around a cylindrical drum. It provides a continuous operation, which is very essential for large capacities. The capacity of this machine is four or five times greater than that of the ordinary bolting reel; it occupies less floor space and is very efficient in operation. These machines are motor driven from the top and the operation is comparatively quiet. It aërates the powder, thoroughly blending any materials of lighter or heavier density, and will even operate successfully where slight traces of moisture are present. The material passing through the screen has the appearance of a cloud, and the sifting of all powders can be taken care of.

A few of the users of this machine are: Pompeian Co., Cleveland and Toronto; the Armand Co., Des Moines, Iowa; Potter Drug & Chemical Co., Malden, Mass.; Andrew Jergens Co., Cincinnati, Ohio; Columbia Carbon Co., Charleston, W. Va.; Crown Chemical Co., Indianapolis, Ind.

New Chemical Pump

The Arrow Pump Co., Buhl Building, Detroit, Mich., has incorporated its ring-oiled packing gland feature in a motor-driven centrifugal pump. While it is an economical and effective unit for a number of various purposes, it is distinctly so in chemical industry service, where it is important that a pump be immune from injurious effects of the liquid being handled.

The construction protects the bearings from coming in contact with the liquid being pumped and provides a positive supply of oil to them with its ring oiler. It is a centrifugal pump with only one working part, the impeller, which will wear indefinitely in most services. A priming chamber in the pump enables it to retain its prime and work within its suction capacity above the level of the supply without the use of mechanical prime retainers such as foot or check valves which in service where liquid contains foreign matter are not dependable on account of such substance



ARROW CENTRIFUGAL PUMP

preventing valves from seating tightly.

The unit is compact. It requires no base and can be assembled for floor or side wall mounting. As both motor and pump bearings are ring oiled from large oil wells, they may be located in isolated places where little or no attention is given them over long periods.

Pendulum Hardness Tester

Edward G. Herbert, Ltd., of Manchester, England, has put on the market an interesting machine for testing hardness. As seen in the illustration, the instrument is unique and simple. A yoke, containing adjustable weights, is balanced upon a ball of ruby or of steel 1 mm. in diameter. By means of the adjusting nut immediately above its support, the position of the inclosed weights, and therefore of the center of gravity of the entire instrument, may be varied somewhat. For ordinary tests, these adjustments are so made that the center of gravity is slightly below the ball, the entire mechanism being equivalent to a pendulum 0.1 mm. in length.

If this instrument is placed carefully upon a surface, is tilted to one side until an attached spirit level comes to zero and is then released, it will swing pendulum fashion, the oscillations gradually decreasing owing to the fact that some energy is absorbed by the supporting ball rolling out or elongating the original indentation. Consequently the energy absorbed in thus displacing the metal is taken from the potential energy of the pendulum, and the swing is shortened. The position of the bubble on the scale at the end of the first swing shows the work done by the ball on the specimen and measures its hardness.

DETERMINING HARDNESS OF A MILLING CUTTER HELD IN A UNIVERSAL FIXTURE

SHRIVER DIAPHRAGM PUMP

Another useful method of conducting the test as recommended by the makers is to measure the time consumed in making ten swings. It is stated that tests taken either way are consistent among themselves and comparable each to each. An empirical relationship between hardness as determined by the pendulum hardness tester and the Brinell hardness scale has also been established.

Diaphragm Pump for Filter Presses

A pump designed with parts moving in the liquid pumped is liable to excessive wear when pumping liquids containing gritty solids in suspension, such as are encountered in filter press work. With this fact in mind, T. Shriver & Co., of Harrison, N. J., have designed and are now marketing a diaphragm pump for use in conjunction with this filtering equipment.

In this pump the diaphragm is moved by a series of concentric rings on the one side and by a crescent shaped disk on the other. It is supported at all points during the discharge stroke and should have a very long life. The diaphragm and liquid end can be removed for cleaning or replacing in a few minutes by taking out a few bolts. The liquid passages are oversize so as to minimize friction, and the ball valves are of the self-cleaning type. The moving parts run in a bath of oil.

The makers claim that this pump is very efficient, generates pressure up to 100 lb. and has a very good suction lift. It is of the duplex type and is fitted with a large expansion chamber. The pressure generated is steady and shows very little fluctuation. The liquid end, being a simple casting, can be made of suitable materials such as cast iron, bronze, lead, hard rubber, etc., and the pump can be used for handling acids and corrosive liquids by choosing a suitable liquid end.

Correction

To the Editor of Chem. & Met., Equipment News Department:

SIR—I note that you inserted, on May 28, an article on our C-22 brick under the heading of "High-Temperature Refractory." This is unfortunate, for our material is not recommended as a direct refractory except in certain cases, and we are anxious not to create an impression that might cause misuse of the material.

It is true, of course, that it will withstand conditions which in many cases would classify it as a refractory material. The material, however, is recommended and used as an insulating material and is very seldom exposed directly to the action of furnace gases, as is often the case with refractory materials.

We trust, therefore, that you will make this correction in an early issue of *Chemical & Metallurgical Engineering*.

Review of Recent Patents

Of Interest to the Ceramic Industries

Developments in Manufacture of Glass, Refractories and Electrical Insulators

WITH the development of continuous tanks, automatic blowing machines and traveling leers, the production of bottles has become almost automatic. There is a break, however, between the blowing machines and the leers, this transfer being made almost entirely by hand, although a great deal of thought is directed toward the elimination of manual labor at this point. For example, Michael J. Owens has offered a solution in patent 1,455,966, issued May 22, 1923, and assigned to the Owens Bottle Co. As the bottles or other objects are hot and somewhat plastic as discharged from the forming molds, means must be provided for preventing them from knocking against one another or coming in contact until they have cooled to a certain extent. For this reason, the bottles slide down an inclined chute from the forming machine to a rotating disk, from which they are delivered by means of a stationary deflector to a belt conveyor which extends into and across the feed end of the leer. It is evident that the disk will serve to space the bottles on the carrying-in belt and thus prevent contact. If desired, the disk may be perforated and air blown through to assist in cooling the ware. From the carrying-in belt, the ware is discharged periodically onto the leer conveyor by means of a cam-operated pusher bar.

Improving Structure of Bauxite Refractories

In order to destroy the cleavage planes present in natural materials such as bauxite used in the manufacture of refractories and at the same time obtain properties which will permit molding without the use of a bond, Louis P. Kraus, Jr., of New York, first mixes the material with twice its volume of ground wood. An aqueous bonding agent is added and the mixture formed into blocks, which are dried and then heated to within 300 deg. F. of the melting point of the refractory material. The blocks are then crushed to the desired extent. The refractory material thus formed is composed of refractory grains of highly irregular shape with rough surfaces well adapted to knit together under pressure and with a high percentage of voids, the material being of a highly spongy nature. It can be compressed and molded dry with no bonding material, and is then able to withstand burning in the kiln to a higher temperature than usual, thus giving a more serviceable product. (1,453,468; May 1, 1923.)

Slag Substitute for Magnesite Brick

Magnesite converter linings are subject to rapid deterioration and their renewal is frequently a matter of serious concern, for there are times and localities when and where it is practically impossible to obtain magnesite brick. Attention is called by Calvin Payton of Douglas, Ariz., in patent 1,453,993, issued May 1, 1923, to a substitute which is readily available wherever a converter is being run. This is nothing more than converter slag so prepared as to be high in magnetite and low in silica. Copper matte is blown in a converter without the addition of the usual excess silica and, as

American Patents Issued June 5, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,458,167—Method of and Apparatus for Feeding Molten Glass. S. Davidson, Hillsboro, Ill., assignor to Schram Glass Mfg. Co., St. Louis, Mo.

1,458,204—Pump. R. W. Tibbetts, Roxbury, Mass.

1,458,234—Separating Solids From Liquids. H. C. Miller, Bakersfield, Calif., assignor to Standard Oil Co. of California.

1,458,256—Cellulose Ether Composition. A. P. H. Trivelli, Rochester, N. Y., assignor to Eastman Kodak Co.

1,458,273-4—Welding Apparatus and Process. M. S. Clawson, Upper Montclair, N. J.

1,458 283—Furnace for Melting Metals. G. D. Faulds, Philadelphia, Pa.

1,458,291—Apparatus for Dehydrating Petroleum Oils. F. W. Harris, Los Angeles, Calif., assignor to the Petroleum Rectifying Co.

1,458,309-10—Method and Process of Making Sulphite and Bisulphite Liquors. G. A. Richter, Berlin, N. H., assignor to the Brown Co., Berlin, N. H.

1,458,322—Process of Manufacturing Abrasive Disks. S. M. Bullock and H. S. Lloyd, Chicago, Ill.

1,458,338—Height Indicator for Liquids. R. Grimshaw and C. J. Weis, Clyde, Ohio.

1,458,351—Method and Apparatus for Producing Carbon. C. Matlock, Brooklyn, assignor to Munroe-Louisiana Carbon Co., Munroe, La.

1,458,357—Apparatus for Extracting Volatile Matter. C. Postel, New York City, assignor to American Shale Reduction Co., New York City.

1,458,376—Method of Making Ceramic Products. Edward Anderson, Dayton, Ohio, assignor to the A. A. Simonds-Dayton Co., Dayton.

1,458 389—Manufacture of Viscose Silk. E Bronnert, Mulhouse, France.

1,458,403—Vacuum Dehydrator. C. E. Glessner, Portland, Ore.

1,458,410—Method of and Apparatus for Producing Charcoal and Byproducts. S. Hiller, San Francisco, Calif., assignor to Pacific By-Products Co., San José, Calif.

1,458,442—Method of Storing Salt. A. Schilling, San Francisco, Calif.

1,458,443—Process of Treating Hydrocarbons. A. Schwarz, Montclair, N. J., assignor to the Petroleum Sand Products Corp. of Delaware.

1,458,461—Process for Bleaching Barytes. L. K. Ayers, St. Louis, Mo.

1,458,467—Method of and Apparatus for Concentrating Ores. S. H. Dolbear, San Francisco, Calif., assignor of one-half to E. L. Oliver, San Francisco.

1,458,478—Process of Producing a Catalyst From Vanadium Pentoxide and the Product Thereof. H. D. Gibbs, Penns Grove, N. J., dedicated to the government and people of the United States.

1,458,491—Method of Making Oxidized Aromatic Substances. R. H. McKee, New York City, and H. C. Cooper, White Plains, N. Y., assigned to said McKee.

1,458,491—Apparatus for Mixing. P. L. Mathews and R. M. Willis, Newark, N. J.

1,458,493—Varnish Composition. L. Mauerhofer, New York City.

1,458,525—Process for Fixation of Atmospheric Nitrogen. F. Daniels, East Falls Church, Va., and O. R. Wulf, Norwich, Conn.

1,458,542—Process for the Manufacture of Dispersoids. H. Plauson, Hamburg, Germany.

1,458,543—Condensation Product and Method of Making Same. F. Pollack, Vienna, Austria.

1,458,568—Method of Producing a Rustless Iron Alloy. W. Bennett, Wellington, New Zealand.

1,458,595—Process for Utilizing Impure Gases or Exhaust Gases Containing Carbon Dioxide. F. Riedel, Essen, Germany, assignor to Riedel Fertilizing Process Co., Elizabeth, N J.

1,458,646—Process for Absorbing Ethylene and Its Homologs. R. Engelhardt, W. Lommel, A. Assenbeck, Cologne, Germany, assignors to Farbenfabriken, Leverkusen, Germany.

1,458,650-1—Process for Production of Calcium Chloride. V. M. Goldschmidt, Christiania, Norway.

1 458,670—Manufacture of Alkylized Derivatives of Hydrocupreine. H. Thron, Frankfort, assignor to Vereinigte Chininfabriken Zimmer & Co., Frankfort, Germany.

1,458,715—Process of Making Nitrobenzoic Acid and Intermediates. E. A. Lloyd, New York, and V. P. Gershon, Brooklyn, N. Y., assignors to W. M. Grosvenor, New York City.

1,458,723—Refractory Compositions. J. L. Ohman, Buffalo, N. Y., deceased, by C. A. White, assigned to Buffalo Refractory Corp., Buffalo.

1,458,858—Process of Producing Homogeneous Porous Materials. M. O. Sem, Christiania, Norway, assignor to Norsk Industri Hypotekbank, Christiania, Norway.

1,458,898—Registering Mechanism of Gas Analysis Apparatus. O. Rodhe, Stockholm, Sweden.

1,458,899—Refrigerating Apparatus. H. W. Wolfe, Philadelphia, Pa.

1,458,913—Non-Recrystallized Refractory Material. W. A. Farish, Buffalo, N. Y., assignor to the Buffalo Refractory Corp., Buffalo, N. Y.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

a result, a slag high in magnetic iron oxide and low in silica is produced, and this slag while molten may be poured into suitable molds and will upon cooling form bricks which may be employed for the purpose stated. In producing this magnetite slag, in the manner above pointed out, the temperature within the converter will rise as high as 2,600 to 2,700 deg. F., and it is at this temperature that the rapid oxidization of the iron content occurs and the magnetic oxide is formed. As the ordinary working temperature of a converter ranges from 2,200 to 2,350 deg. F., it will be understood that a lining of the magnetite slag will readily withstand this lower temperature. Of course the slag may be employed in various ways. It may, as stated, be molded in the form of bricks, it may be cast in lining sections of various shapes and dimensions, crucibles may be cast therefrom, and in fact the material may be employed as a lining or as a body material wherever the reduction of metals by fusion is to be accomplished.

Electrical Insulators From Powdered Talc

Massive or solid talc, when free from seams or fissures, is in itself highly di-electric and is especially adapted for use in insulating articles, but is impractical from a manufacturing standpoint owing to the difficulty of obtaining large quantities in block form free from fractures and uniform in texture. It has also been found almost impossible to mold powdered talc and subsequently treat it without minute fractures being formed. It has recently been noted, however, that phenol condensation products may be used as temporary binders for powdered talc with excellent results. The mixture is molded into the desired shape under pressure, which for spark plug cores may be 25,000 lb. per sq.in. It is also desirable to apply a vacuum to the mold just before compressing, in order to eliminate entrained air. Heating to 200-400 deg. F. puts the molded material in condition for machining to final shape and dimensions, allowance of course being made for the slight, very uniform shrinkage which occurs in the subsequent operation of heating to about 2,000 deg. F. In some cases, the di-electric capacity at high temperature may be increased by impregnating the ware with soluble metallic compounds, sulphates and chlorides of aluminum, iron and chronium being preferable. After this treatment, the ware is again heated. (1,453,726; Theodore C. Prouty, of Los Angeles, assignor to Proutyline Products Co., May 1, 1923.)

A Filter Press for Wax

The filtration of paraffine wax from chilled oil is in many ways an ideal filtering operation, particularly in the ease with which the filter cake can be removed from the press. High-pressure steam is normally used for the purpose of melting the wax away from the plate. Difficulties, however, are often encountered in completely removing the cake in this manner, and it is for the correction of these difficulties that George H. Fifield, of Culver, Ind., has been granted a patent, assigned to the Standard Oil Co. of Whiting, Ind. He provides a filtering apparatus, circular in form, having openings at least half the radius of the disks above their centers. On either side of the plate is mounted a disk of woven wire, provided with openings aligning with those in the plate.

In the process of removing the wax, steam is introduced through a small pipe in the inside of the larger filter openings. The heated pipe melts the wax surrounding it and enlarges the open passage for liquids through the press. Water, preferably at about 200 deg. F., is then introduced into this passage and rapidly melts the wax in the press. The relatively high position of the liquid passage through the press causes all the wax above the passage as well as below it to be melted. The melted wax drains through the filter cloth and out of the press, being separately collected for further treatment after separation of water from the melted wax by settling.

In many cases the introduction of steam for the purpose of melting the wax in the passageway may be entirely dispensed with, the hot water being directly introduced into the press and traveling through same channels as the oil and wax. (1,455,436, issued May 15, 1923.)

Book Reviews

Mechanical Preparation of Ores and Minerals

Authoritative Treatment of an Important Phase of Chemical and Metallurgical Engineering

BY A. W. ALLEN
Assistant Editor, *Chem. & Met.*

TEXT BOOK OF ORE DRESSING. By S. J. *Truscott.* 680 pp, illus. New York: The Macmillan Co. Price, $11.

In these days of too-frequent irresponsible publication it is a pleasure to welcome the appearance of a technical treatise that breathes the atmosphere of the operating plant, yet withal is characterized by the ease of scholarly presentation. The treatise under review is such; and there can be no doubt that it will be given front rank among text books on the subject, which is one that is so intimately connected with chemical and metallurgical engineering that no excuse need be made for the appearance of a review in these pages.

The inadequacy of existing text books is given in the preface as the principal reason for the compilation of the volume; to the contention that such inadequacy exists few will disagree. Professor Truscott modestly attributes his competence for the task mainly to the published work and experiences of others. Lest this should be taken too literally, it will not be amiss to point out that he achieved an international reputation as a successful engineer and technical writer long before becoming professor of mining at the Royal School of Mines in London.

All text books on ore dressing begin with a definition of the term, which, to Professor Truscott, comprises "that series of preparatory operations to which crude ore is submitted till any further work to extract the metalliferous content is best conducted metallurgically." The impossibility of limiting the scope of metallurgical operations permits considerable latitude in the definition. The present volume deals with comminution, sizing, gravity concentration, flotation, magnetic and similar types of separation. Other text-book writers have included amalgamation as an essential phase of ore-dressing operations. Almost all consider flotation outside of consideration, possibly because it is a comparatively recent art. There may be disagreement that its practice should now be considered as non-metallurgical. "A few years ago I endeavored to simplify matters by pointing out that "the various processes involved in the extraction and recovery of the valuable portions of an ore have specific designations," and that a clarification of ideas on the subject might result if ore dressing were considered as "covering the reduction or other mechanical handling of the ore, whereby one or more products are obtained in a condition to be treated for the isolation of their valuable contents by amalgamation, concentration, wet-chemical, smelting or other process of recovery." The disadvantage of Professor Truscott's classification is that flotation metallurgists and millmen may ignore the book, thinking that their specialty is not treated; others may be disappointed at the exclusion of what they have been accustomed to find in standard text books. However, these comments are by the way and of little moment. If fault can be found with

the book, it will be that the author has been generous in his interpretation of the scope of the subject, and readers will benefit accordingly.

Comminution is dealt with in a thorough manner. A discussion of the theory of crushing shows that the Kick-Rittinger controversy is by no means dead. Strong support for Kick's law is based on the fact that "if bodies of the same material and shape but of different mass be dropped separately from a height just sufficient to break them, it will be found that the height is much the same whatever the mass. Dropping from the same height the velocity factor in the energy developed remains constant, and that energy must vary as the mass; and since in each case the result is fracture, it may be assumed that the energy required to produce fracture varies as the mass or volume of the piece."

Chapters on sizing and what is termed water concentration are followed by a well-rounded account of the flotation process—methods, machines, agents, general aspects and theory. A feature of the book is the thorough manner in which magnetic, electrostatic, pneumatic and centrifugal separation has been treated. Final chapters discuss heat-treatment, the control of operations, ore-dressing systems and plants. Taken altogether, the volume gives evidence of careful and painstaking presentation, based on an intimate knowledge of the subject and an ability to present facts and theories with unusual clarity of expression. It will take its place in every technical library as an essential book of reference on the mechanical preparation and concentration of ores and minerals.

Elements of Agricultural Analysis

QUANTITATIVE AGRICULTURAL ANALYSIS. By *Edward G. Mahin, Ph.D.* and *Ralph H. Carr, Ph.D.* 329 pp. McGraw-Hill Book Co., Inc., New York. Price, $2.75.

The authors state in the preface, "We recognize the futility of attempting to train students for technical or professional careers by teaching them only the technical notions and processes of chemistry without the scientific development of fundamentals." They have then proceeded, with this thought clearly in mind, to produce an excellent small volume dealing with the chemical analysis of agricultural products.

Part I contains chapters on the theory and general principles of analysis of most interest to the student of agricultural chemistry, with methods for the determination of some of the more common elements.

Part II covers special measures—namely, density and specific gravity, heat of combustion, index of refraction, optical rotation and hydrogen-ion concentration. In Part II the authors have performed a distinct service in emphasizing the importance to every chemist of a knowledge of the instruments and methods used in industrial work. It is to be regretted that the size of the volume limits, in several instances, a more detailed description of some of the instruments employed in every well-equipped laboratory.

In Part III consideration is given to the materials and products of chief interest to the agricultural chemist, such as feeds, oils, fats and waxes, dairy products, soils, fertilizers, insecticides and fungicides. The methods given for the necessary determination of the constituents of these products are, as stated by the authors, official where practicable.

The book is so well gotten up and such a valuable addition to our text books on chemistry, it is hoped that its reception may be such as to induce the authors to prepare a larger and more comprehensive text along similar lines.

W. W. SKINNER.

Metals and Alloys

METALS AND THEIR ALLOYS. By *Charles Vickers.* Henry Carey Baird & Co., New York. 6x9 in., xix plus 767 pp., with 110 engravings. Price, $7.50.

Mr. Vickers has prepared a book that as a practical treatise on the non-ferrous metals and alloys is almost encyclopedic in its scope. Although conceived originally as a revision of Brannt's "Metallic Alloys," the necessary process of modernization has produced a work that is altogether unrecognizable as any kin of its acknowledged progenitor, and Brannt's name is preserved probably through sentiment on the part of its author. The book is comprehensive almost to a fault, including as it does nearly all that one would expect in the way of topics in a book on non-ferrous metals and several things—for example, a very casual chapter on iron, steel, cast iron, etc.—that could very logically have been omitted. Without the one chapter on iron the book would be 100 per cent non-ferrous. The one-book type of student turning to non-ferrous metallurgy would find this work a wonderful boon, because between its two covers is embraced something about almost everything.

One of several things that add value to this work is the fact that the author has drawn liberally from current technical journals and other more fragmentary sources for much of his material. This has given it an air of freshness and helped produce a volume that in matter is representative of modern conditions. Of course the specialist will find considerable that has been overlooked or that is slightly incorrect in reference to his own peculiar field, which will ever be the fate of general treatises.

One of the best chapters and by far the longest is the one on the history, production methods, properties and uses of the elements, especially those of metallurgical importance. Also the two chapters on the history, fundamentals, definitions and characteristics of alloy groups contain information of decided educational value to more than a few foundrymen and other metal workers. In the section on hardness and strength it is to be regretted that the important theories of Jeffries and of Rosenhain have not been included.

The chapter on alloying and melting is slightly too attenuated for so large a subject. Brasses and bronzes are treated quite fully in a half-score chapters on copper, aluminum bronze, copper-tin alloys, bell metal and other hard bronzes, phosphor and silicon bronzes, railroad alloys, steam metals and red brass, brass for rolling, brass for sand casting, manganese bronze and white brass. The industrially important light aluminum alloys receive a full chapter, but not nearly so much space as is given to the less important aluminum bronzes.

A noteworthy chapter, and one that our book literature has needed for some time, is that on nickel alloys, including Monel metal. Tin alloys and lead alloys each receive a chapter; and in the former the babbitt metal formulas of the Society of Automotive Engineers are missing; in fact the inclusion of the S.A.E. alloys in several other places in the book would have added considerable interest in this motorized age. Near the end of the book there is a chapter on the chemical analysis of babbitt metals—the only discussion of analysis in the whole book—that seems unnecessary in a work of this type.

The chapter on amalgams should be

Important Articles In Current Literature

More than fifty industrial, technical or scientific periodicals and trade papers are reviewed regularly by the staff of *Chem. & Met.* The articles listed below have been selected from these publications because they represent the most conspicuous themes in contemporary literature, and consequently should be of considerable interest to our readers. Those that are of unusual interest will be published later in abstract in this department; but since it is frequently impossible to prepare a satisfactory abstract of an article, this list will enable our readers to keep abreast of current literature and direct their reading to advantage. The magazines reviewed have all been received within a fortnight of our publication date.

THE COLLOID MILL. Anonymous. Current British practice in the use of Plauson's apparatus for producing colloidal solutions. *Engineering* (London), June 8, 1923, pp. 705, 706.

BULK MATERIALS HANDLING AND THE COMMON LABOR SHORTAGE. Matthew W. Potts. The various types of apparatus available and methods of operation described from the labor-saving standpoint. *Industrial Management*, June, 1923, pp. 338-345.

SEPARATING THE GASES FORMED IN THE *n*-BUTYL ALCOHOL-ACETONE FERMENTATION PROCESS. E. W. Blair, T. S. Wheeler and J. Reilly. Investigation of a fractional solution method for separation and collection of carbon dioxide and hydrogen. *J. Soc. Chem. Ind.*, June 1, 1923, pp. 235T-240T.

RECENT DEVELOPMENTS IN CHEMICAL PLANT. Arthur B. Scover. (*a*) Details of an acid-resisting centrifugal pump with equivalent height of lift 100 ft., delivery 4,500 gal. per hr., sp. gr. 1.7. (*b*) A new type of gas scrubber. *J. Soc. Chem. Ind.*, June 1, 1923, pp. 240T-242T.

THE SORPTION ACTIVITY OF CARBON. J. B. Firth. Method of activation, factors affecting activity and theory of mechanism. *J. Soc. Chem. Ind.*, June 1, 1923, pp. 242T-244T.

PROFIT AND LOSS METERS FOR STEAM PLANTS. S. H. Childs. Application of a standard cost system to the paper mill. *Paper Trade Journal*, June 14, pp. 57-59.

very welcome, since it contains considerable matter of not very common knowledge. Another chapter valuable for the same reason is the lengthy one on the alloys of the precious metals. Fusible alloys, along with cadmium and bismuth, receive such recognition as is due.

Other subjects treated in separate chapters are magnesium alloys, zinc alloys, die castings and their alloys, soft solders and brazing alloys, and miscellaneous alloys. The chapter on the surface coloring of alloys is well worth while. The closing chapter is a general miscellany of the usual nondescript data that is more or less typical of foundry handbooks. This chapter ends with a rather anemic glossary which needs careful revision. For example, "binder" in many foundries means something quite other than a mechanical clamp for molds; nor is "air-hole" a correct definition for "blow-hole"; also if "facing" is defined, why is "parting" omitted? and lastly we do not believe that many authorities will agree that an alloy may be defined always as a solid solution of two or more metals.

The book has the great advantage of having been written by an experienced technical writer whose English is clear and facile. For this reason as well as for its wealth of material and for its freshness this book is to be recommended. G. K. ELLIOTT.

New Publications

DIE ENTWICKLUNG DER CHEMISCHEN TECHNIK, BIS ZU DEN ANFÄNGEN DER GROSSINDUSTRIE. By Gustav Fester. Published by Verlag von Julius Springer, Berlin, Germany. Price $1.80 A comprehensive history of chemical technology from the time of the early Egyptians to the beginning of the nineteenth century

COLUMBIA UNIVERSITY has published Engineering and Scientific Paper 12, April, 1923, on "Comparative Tests of Clay, Sand-Lime and Concrete Brick Masonry," by Albin H. Beyer and William J. Krefeld, of the department of civil engineering

THE UNIVERSITY OF MINNESOTA has issued Bulletin 2, from the Engineering Experiment Station, on "The Manufacture of Portland Cement From Marl," by Raymond E. Kirk.

THE BUREAU OF STANDARDS has revised the Mollier chart of the properties of ammonia, which is available as Bureau of Standards Miscellaneous Pub 52.

AMERICAN SOCIETY FOR TESTING MATERIALS, twenty-sixth annual meeting, Chalfonte-Haddon Hall Hotel, Atlantic City, June 25 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (NINTH), New York, Sept. 17-22.

NATIONAL SAFETY COUNCIL, twelfth annual safety convention, Statler Hotel, Buffalo, Oct. 1 to 5.

Men in the Profession

KENNETH E. BELL has resigned his position with the Lewis Recovery Corporation to accept one as chemical engineer for the A. C. Lawrence Leather Co., Peabody, Mass.

C. F. CARRIER, JR., general manager of the Carrier Chemical Co., Charleston, W. Va., will address the annual convention of the West Virginia State Pharmaceutical Association. His topic will be "Contact Points."

EDWARD B. DURHAM has accepted the position of engineer for the Mammoth Plant of the U. S. Smelting, Refining & Mining Co., at Kennet, Shasta Co., Calif., and will take up the work there before July 1. He was formerly maintenance engineer for the Standard Chemical Co. at Canonsburg, Pa., and since March 1, 1923, has been with the Koppers Co. of Pittsburgh, Pa.

F. M. FEIKER, formerly vice-president of the McGraw-Hill Co., Inc., and more recently on leave of absence as special agent to the Department of Commerce at Washington, will, after his return from Washington, be associated with the staff of the Society for Electrical Development, New York City. Mr. Feiker will retain a consulting relation to the McGraw-Hill Co., Inc., and he will continue in a similar capacity his relation to the problems of personnel and organization of the Department of Commerce.

P. J. FREEMAN, for the past 7 years engineer of tests at the Pittsburgh Testing Laboratory, has opened offices for private practice as a consulting engineer at 311 Ross St., Pittsburgh, Pa.

DR. E. C. GANGLOFF, formerly research chemist with the National Aniline & Chemical Co., is now chief chemist with Dextro Products, Inc., Buffalo, N. Y.

J. H. HILDEBRAND, professor of chemistry at the University of California, has been appointed dean of men—an office recently instituted by the president-elect, Dr. W. W. Campbell. The appointment is a popular one, especially among the young men of the campus, by whom Dr. Hildebrand is held in high esteem.

JOHN F. KELLER of Purdue University gave an interesting address on the subject of steel and treatment of steel before a meeting of Columbus, Ind., manufacturers, at the Columbus Chamber of Commerce rooms, June 12.

A. R. KEMP, a graduate of the California Institute of Technology, arrived at Pasadena, Calif., recently, to undertake chemical and engineering work in connection with the laying of two telephone cables between San Pedro and Catalina Island. Mr. Kemp left the Institute in 1918 to accept a position as research chemist with the Western Electric Co. in New York. He has given particular study to the development of an insulating material for submarine cables.

PROF. G. N. LEWIS, dean of the college of chemistry of the University of California, has been granted leave of absence from July 1 to Dec. 31, 1923, to serve as a representative of the United States at the International Union of Pure and Applied Chemistry in England.

WILLIAM H. PIERCE has been elected vice-president of the American Smelting & Refining Co., New York, in charge of refinery operations at Baltimore, Md., Perth Amboy, N. J., and Omaha, Neb.

FRANK N. SPELLER, metallurgical engineer of the National Tube Co., Pittsburgh, Pa., received the honorary degree of Doctor of Science from the University of Toronto at its convocation, June 7.

GERALD SWOPE, president of the General Electric Co., Schenectady, N. Y., received the honorary degree of Doctor of Science at Rutgers College and State University of New Jersey, New Brunswick, at commencement, June 12.

CHARLES P. VAUGHAN of Philadelphia, Pa., president of Dungan, Hood & Co., Inc., manufacturer of glazed kid, and also president of the Philadelphia Chamber of Commerce, has sailed for Europe, where he will make a study of conditions in the leather industry in twelve different countries. He will be absent for 3 months.

DR. W. R. WHITNEY, director of the research laboratory of the General Electric Co., was recently elected a member of the corporation of the Massachusetts Institute of Technology for a term of 5 years. He was graduated from M.I.T. in 1890 and has for some time been a non-resident professor of theoretical chemistry at the institution. WALTER HUMPHREYS, '97, of Brookline, and CHARLES R. MAINE, '09, a prominent consulting engineer of Boston, were also elected to the corporation, these three succeeding PAUL W. LICHFIELD, ARTHUR D. LITTLE and EBEN S. STEVENS.

Obituary

PAUL SCHNORIENBERGER, general manager of the Heller & Merz Co., New York and Newark, N. J., died suddenly of heart disease, June 11, while seated at his desk. He was 74 years of age.

CHARLES F. WELLS, of Pittsburgh, Pa., vice-president and treasurer of the National Lead & Oil Co., died June 11, at Cedarville, Mich., where he had gone about 2 weeks previously. He was 62 years of age.

Industry and Trade

Current News and Market Developments

Summary of the Week

Oil litigation involving $800,000,000 under way in San Francisco court.

Chemical Foundation suit, adjourned for week, makes little progress.

Society for the promotion of engineering education holds important meeting at Cornell.

German financiers announce founding of factories in this country.

United States Bureau of Standards will be asked to evolve standard test for imported coal-tar products.

Rhineland High Commission places June 30 as latest date for filing applications for import and export trade with the Ruhr.

Casein probably will be first of chemical items to be granted hearing by Tariff Commission.

Leading sellers of soda ash and caustic soda announce that prices will be quoted hereafter on flat basis.

Bureau of Census report on cottonseed products shows stocks of cottonseed oil smaller than a year ago.

Lack of funds may restrict personnel of customs service throughout coming year.

Demand for calcium arsenate has not become active and prices are irregular.

Trading in cottonseed meal futures will be opened up at Memphis on July 1.

Department of Commerce will issue import and export statistics simultaneously, having caught up on import figures.

Imported copper sulphate has recovered from recent price weakness.

Arsenic is unchanged on spot, but futures were lower in price.

Foreign makers of prussiates appear eager to hold American trade and prices are weak under this selling competition.

Poduction of coke from byproduct ovens amounted to 3,328,000 net tons in May, which was an increase of 3.8 per cent over April.

High protective tariff on sulphur proposed in Spain, in order to stimulate activity in the industry.

U. S. General Appraisers give decision, holding that tankage is subject to import duty of 10 per cent ad valorem, as waste.

Consumption of Cottonseed Oil in May Estimated at 128,871 Bbl.

Bureau of Census Report Shows Light Stocks—Visible Smaller Than Last Season—Demand Less Active

THE DISTRIBUTION of refined cottonseed oil into consuming channels during the month of May, according to an analysis of the Bureau of Census report on cottonseed products for the 10 months ended with May 31, amounted to 128,871 bbl. This compares with 151,233 bbl. in April and 179,770 bbl. in May a year ago. In view of the low position of lard and the inability to export, because of the high prices, the consumption for the month of May was considered good. The report revealed nothing new to traders and the tight statistical situation was offset, as a market factor, by the less favorable condition of the vegetable oil trade.

The visible supply of refined oil on the last day of May, converting the stocks of crude oil and seed at the plants into refined, was placed at 627,000 bbl., which compares with 707,000 bbl. on the corresponding day a year ago. Seed not yet accounted for will produce approximately 38,000 bbl. of refined oil, against an actual production of 25,000 bbl. for the last 2 months of the 1922 season.

The crop year officially ends with the last day of July, but new oil will not come on the market in a large way before late September. Refiners must hold enough old crop oil in reserve to meet the regular trade requirements and, from present indications, the carry-over, on July 31, will be even smaller than last year, when the total was estimated at 434,325 bbl.

Consumption of refined cottonseed oil for the 10 months ended with May 31, reached the total of 2,040,000 bbl., which compares with 1,975,000 bbl. for this period a year ago.

Average monthly consumption of refined oil for the 10 months ended with May 31 amounted to 203,750 bbl., as against 19 500 bbl. a month for the first 10 months of the previous season. Actual monthly consumption for June and July a year ago was 144,300 bbl. Reports on the condition of trade for the first half of June this year were not encouraging, and operators do not expect so good a showing for the entire month as for June a year ago. The action of competing oils, such as soya, corn and sesame, may have some bearing upon the market. Old crop crude cottonseed oil, during the past week, held at 9c. bid and 9½c. asked, f.o.b. mills, tank car basis. New crop crude (Nov.-Dec.-Jan.) was nominal at 7c. per lb. f.o.b. mills.

Receipts of cottonseed at the mills from Aug. 1, 1922, to May 31, 1923, according to the official report, amounted to 3,208,085 tons, against 2,889,002 tons for the corresponding period a year ago. The amount of seed actually crushed for the 10 months ended with May 31 was 3,193,524 tons, which compares with 2,862,849 tons a year ago.

Production of crude cottonseed oil for the 10 months ended with May 31 amounted to 982,756,658 lb., as against 916,025,098 lb. a year ago. The production of refined oil for the 10 months period amounted to 873,994,702 lb., as against 815,116,501 lb. a year ago.

The output of cottonseed meal for the August-May period was reported at 1,462,327 tons, as against 1,335,373 tons a year ago.

The stocks of seed at the plants on the last day of May amounted to 23,098 tons, which compares with 23,880 tons on the corresponding date a year ago. The stocks of crude oil on May 31 were estimated at 24,195,802 lb., which compares with 23,703,854 lb. a year ago. The stocks of refined oil on hand on May 31 amounted to 222,863,042 lb., as against 254,518,251 lb. on the last day of May a year ago.

Text for Rhineland Order Authorizing Sale of American Owned Goods

Proceeds of Sale Less Expenses Will Form "Consignment Account"—Owner Will Be Reimbursed in Francs

THE TEXT of the order of the Rhineland High Commission, which authorized the sale of goods owned by Americans and also the sale of other merchandise held by the railway lines, was received a few days ago by domestic importers. Translation of the order is as follows:

The Interallied Rhineland High Commission regarding Order No. 149—Considering the fact that, as a result of orders given by the German Government, considerable merchandise remains standing on the railway lines of the occupied territories, and that this fact is such as to affect the interests of the population and to block public service which has been taken over by the Administration of the Railway Lines, it has been necessary, therefore, to take measures in order to remedy this situation.

Article 1—On and after June 10, 1923, cars which remain standing on the railway systems operated by the Administration of Railroads may be unloaded; and the merchandise, whether on the cars or in the warehouses, may be sold under the hereinbelow stated conditions:

Article 2—The Administration of the Railroads in the occupied territories will turn over on June 10 all loaded cars and all merchandise stored in warehouses to the Franco-Belgian Restitution Services, which will have charge of their liquidation.

An official report will be made out for each transfer made by operation of the present article.

Article 3—All claims relative to stalled freight cars or merchandise will have to be forwarded before June 10 to the Franco-Belgian Restitution Services. These will see that they are delivered to the consignees or to the shipper of the merchandise when claimed, and will sell all merchandise whose owners cannot be identified, or which has been refused, or which cannot be forwarded to its destination owing to the refusal of the German Railroad Administration to provide for uninterrupted transportation.

Article 4—Before each sale an official report will be made out, giving as far as possible all particulars which might help to identify the merchandise and subsequently enabling the owners to establish their rights to be paid the proceeds.

This official report will be completed after the sale by stating the price received and expenses reimbursed to the Administration of the Railways and to the Restitution Services.

Article 5—The proceeds of the sale of the merchandise, after deducting the expenses incurred by the Administration of Railways and the Restitution Services, will be entered by the Restitution Services in a special account, to be known as the "consignment account."

During the period of one year the owners of merchandise sold, or their assigns, may obtain, after establishing their claims, reimbursement in French francs of the sums entered in this account.

They will be entitled to no other indemnity, either from the Railway Administration or from the Restitution Services, but all their rights will be reserved as against the German departments whose default shall have caused them injury.

At the expiration of the period of one year, as provided above, the proceeds of the sale will be turned into the treasury of the administration.

Article 6—By derogation of Article 5 above, the Administration of the Railways is authorized immediately upon the expiration of the period fixed in Article 1 to use itself the fuel and generally all other material fit for use in operating the railroads which have been left standing on the tracks.

The value in French francs of this merchandise will be determined by experts appointed by the French-Belgian Restitution Services.

The Restitution Services will make out an official report covering the delivery of such fuel and material.

Article 7—The value of merchandise so utilized by the Administration will be entered in a special account to be kept by the Restitution Services.

Within one year the owners of this merchandise, or those having a right to the same, may, after establishing their rights, claim reimbursement of this value from the Restitution Services.

The Restitution Services, after verifying the rights and the identity of the claimants, will furnish them with a certificate, on the presentation of which the Railway Administration will pay them the amount in French francs of the value indicated in the special account, upon their waiving all future claims against it.

Article 8—The Railway Administration in the occupied territories cannot be considered, in any case, as responsible for damages, losses, diminution in weight or value of merchandise the liquidation of which is directed by this order.

Article 9—Judicial actions relative to differences which might arise from the enforcement of this order will be referred to arbitration commissions, the membership and functioning of which will be governed by an order of the High Commission.

Steel Men to Meet With Ordnance Officers

The board of directors of the American Iron and Steel Institute has accepted the invitation of the Army Ordnance Association to meet with it next fall at the Army Ordnance Proving Grounds, Aberdeen, Md. For this reason the next general meeting of the Institute is to be held at Hotel Commodore, New York City, a day in advance of the date previously set—that is, Thursday, Oct. 25, instead of Friday, Oct. 26. Special train accommodations are to be provided to make the journey on Thursday night so that Friday may be spent at the proving grounds.

Iodine Combine Active

The Iodine Combine, which under its former organization was to have terminated on March 31 last, has extended its time of existence as such to June 30. The object of this association of Chilean producers is to centralize sales and to market their product under terms of mutual agreement. It is now desired to introduce modifications in the statutes of the society, and the extension of the existing system has been made to afford time for study.

The proposed reforms in the statutes have now been drawn up and will be submitted to those interested in the industry. Under these new regulations, the old Iodine Combine will become the Association of Iodine Producers of Chile.

As outlined at the present time the program of the association will include encouragement of the consumption of iodine throughout the world, the consolidation of the industry by uniting all the iodine producers and stockholders of the country, the marketing of the product, the framing of agreements with producers in other countries as to the sale and supply of iodine and finally the defence and progress of the industry.

Thomas Meal Advances in Price in Switzerland

The price of "Thomas meal," a basic slag fertilizer extensively used in Switzerland, has advanced recently because many blast furnaces of the Ruhr district of Germany have been idle on account of the occupation, according to a report from American Vice-Consul William H. Mathee at Zurich.

Authentic reports are quoted by the vice-consul indicating that the production of "Thomas meal" is being reduced daily and that the lack of new stocks will be felt seriously as soon as the demand in Switzerland reaches the peak this summer.

The situation is described as similar to that of the spring of 1922, when, on account of dininished production, the price of this fertilizer rose within a short time from 40 to 48 centimes per kilogram. Today "Thomas meal" is still obtainable f.o.b. Basel for 42-43 centimes per kilogram.

News Notes

Natural clays possessing desirable properties for use in paints, stains, water colors and toilet articles have been discovered by G. C. Carver in the vicinity of Tuskegee, Ala. He claims to have used this clay with marked success in the manufacture of all these articles.

Zinc has recently been supplied to Japan by the Electrolytic Zinc Co. of Tasmania in successful competition with American producers. Japan uses approximately 40,000 tons of the metal annually. Several shipments are reported to have been made from Tasmania.

Three fellowships in the engineering experiment station of Ohio State University at Columbus are being offered jointly by the Department of the Interior and that institution. College graduates who have had sufficient training in metallurgy, pottery or chemistry to carry on ceramic work are eligible. The object in creating these fellowships is to solve definite problems confronting the pottery industry.

A new Spanish glass factory is reported. The company behind the new enterprise has been formed under the auspices of the Compagnie Internationale pour la Fabrication de la Verre, with a capitalization of 3,000,000 pesetas. According to the Reuter dispatch, the Libbey-Owens system is to be employed in manufacture.

An oxy-acetylene welding course has recently been outlined by the American Welding Society. The Federal Board of Vocational Education and the National Research Council have co-operated in the work of preparing this course, which covers the subject from the viewpoint of the person choosing and training candidates. Copies of the course may be obtained by writing the society at 29 West 39th St., New York City.

The iron ore resources of British Columbia are to be surveyed by Dr. G. A. Young of the Canadian Geological Survey. This work was begun last year by Dr. Young, who has made similar surveys in Eastern Canada.

The American Cotton Oil Co., New York, is arranging for curtailment at its different plants. The fourteen mills of the company in the South devoted to crushing will be closed gradually, and will be kept inactive until conditions in the industry improve. The oil and fertilizer plants at Gretna, La., will also be discontinued temporarily. A number of the refining plants of the company will remain on the active list.

Twenty-seven cement-producing mills represent the cement interests in Canada, according to a list just published by the Mines department. These vary in capacity from 200 bbl. per day to 12,000, the greater proportion having a capacity of from 1,000 to 4,000 bbl. daily. The Canada Cement Co., at its Montreal mill, has the maximum capacity of 12,000 bbl.

Copper and brass consumption in England is to be promoted by a new organization formed along much the same lines as the Copper and Brass Research Association in this country. In that country the organization is to be known as the Extended Uses Council. The use of solid brass hardware in place of brassed steel goods is to be particularly promoted.

Another serious oil fire occurred in Pittsburgh on June 15, when a tank at the Atlantic Refining Co.'s plant was struck by lightning. Eighty persons were injured, more than 100,000 bbl. of oil was burned and a damage of upwards of $1,000,000 was done before the flames were controlled after 26 hours of fighting.

The United States Glass Co., Pittsburgh, has taken over the mold-making establishment operated for nearly half a century by the late W. S. McKee. According to present arrangements a complete line of tableware molds and general ware molds will be produced.

The Canadian Salt Company, Ltd., has had to double the capacity of its liquid chlorine plant, which it put into operation last October. The company is also erecting a new caustic finishing building with the latest improvements which will considerably increase the capacity of that department.

Big Oil Suit Starts

Litigation between the Standard Oil Co. of Indiana and the Universal Oil Products Co. is now under way in San Francisco courts. The litigation is said to involve $300,000,000. The patent rights in question are those covering the Dubbs process, which is employed by the Universal company, and the Burton process, used by the Standard Oil Co. of Indiana.

The Universal Oil Products Co. contends, through its attorney, United States Senator James Reed of Missouri, that its patents control the basic procedure for the manufacture of high test gasoline by cracking crude oil. The Standard Oil, disputing the Universal claims of infringement, is represented by Russell Wiles of Chicago.

Approximately half of the world's production of gasoline is said to be manufactured by cracking higher boiling distillates. For that reason the sum involved is enormous. The case is being heard by Federal Judge Holmes Hall, of Sedalia, Mo.

Italy Building Celluloid Industry

Italy is trying to build up a domestic celluloid industry. The decree now before the Parliament carries a duty of 24 cents on the raw material, but an effort is being made to secure a higher rate. A large plant is under construction in the Province of Como.

Mining Engineers Planning Elaborate Fall Meeting

Final announcement of the August meeting of the American Institute of **Mining and Metallurgical Engineers** has been issued. **It is planned to gather** at the Entrance Hall of the Parliament Buildings in Toronto **Monday morning**, Aug. 20. Late **that night the party will start on a tour in a special train, visiting the** nickel operations **at Sudbury** on Tuesday, the silver mines **and mills in the Cobalt region on Wednesday and Thursday. Friday will find the members** in the Kirkland gold district, **Saturday** and Sunday **in the Porcupine district, where is located the Hollinger,** probably the most important gold **mine** in the world that is now operating.

Tuesday, Aug. 28, the party will spend sightseeing in Quebec, Wednesday will be spent at **the asbestos mines** and dressing plant at Thetford. On Thursday and Friday the **technical sessions** and banquet will be held in Montreal. **Cost of the entire excursion, starting** at Toronto and ending at Montreal, is estimated at $200, and includes transportation, pullman accommodations, meals, hotel **rooms and automobile** excursions. Reservations **must** be made prior to July 20.

Fall A.E.S. Meeting Planned

Dayton, Ohio, will be the scene of activities for the fall meeting of the American Electrochemical Society, which is to be held Sept. 27 to 29. An innovation at this meeting will be a round-table discussion of electric furnace brass foundry practice, organic electrochemistry, chlorine and electroplating.

The plans for the meeting also include two symposiums, one on electrochemistry of gaseous conduction, which is in charge of Dr. Duncan MacRae, Research Laboratory, Westinghouse Lamp Co., Bloomfield, N. J. and another on recent progress in electrolytic refining; chairman, F. R. Pyne, U. S. Metals Refining Co., Carteret, N. J.

Trips and social events will be announced later.

Larger Candelilla Wax Shipments From Nuevo Laredo

Exports of candelilla wax from Nuevo Laredo, Mexico, from Jan. 1 to April ' were 82,233 lb., which is more than the grand total for the 4 years preceding.

The practically sudden demand for the candelilla is attributable to four or five factors, but the chief explanation is unquestionably found in a low price combined with the fact that the candelilla and its uses are becoming more widely known. The present movement is probably for the account of European factories, since all of the shipments through here have been consigned to commission houses of New York City. The current prices in Nuevo Laredo average 18.5c. per pound, which is the record low quotation for the local market.

Washington News

Slow Release of Imports May Continue Over Next Year

With imports pouring into the country in quantities far surpassing any previous period, officials of the Treasury Department are confronting a problem of rendering service to the business interests involved, with a personnel smaller than the force of the Customs Division before the world war and which has just been given the additional duty of enforcing the regulations prohibiting vessels entering American waters from carrying intoxicating liquors.

Drastic reduction of the customs force in the last half of June because of an approaching illegal deficit was avoided only by the intercession of President Harding, who authorized a $60,000 deficit. The appropriation available for the fiscal year 1924, beginning July 1, for collection of customs revenues with all the duties placed upon that division of the Treasury Department, is less than $12,000,000.

Treasury officials frankly confess that unless there is a very decided decrease in imports, the appropriation available for the new year will not provide sufficient personnel to handle imports expeditiously and at the same time protect the revenue of the government. It has been difficult to hold a force of laborers at the government piers because of a limitation of $1,080 a year on the wages paid such workers. This condition has been relieved by a special law removing the limit but without providing additional funds for payment.

Congestion at New York has been relieved to a large extent, customs officials report, by dock inspections of imports, thus avoiding transfer to the appraiser's stores, and by inspecting one case as a sample of a shipment of a number of cases. They do not feel, however, that this system sufficiently protects the revenues.

With prohibition work put upon the Customs Division, thus diverting the activities of part of the force, conditions after July 1 threaten to be more serious in delaying imports than they have been unless some remedy not yet discovered is worked out.

Heavy Lac Exports From India

During the first 3 months of 1923 the exports of lac from India to the United States totaled approximately 96,000 chests of 164 lb. each. Exports to the end of April are expected to bring this figure up to 125,000 chests, which, for the 4 months, will represent about one-half the normal annual shipments to the United States. The principal lac crop comes in May and June, with heavy exports to America usually taking place in the fall, so that the figures for shipments during the early months of this year appear quite large.

Standards Bureau Giving Dyes Much Attention

Problems of dye standardization are receiving intensive attention at the Bureau of Standards of the Department of Commerce. One chemist is devoting exclusive attention to this subject and it is hoped to add to the facilities after the new fiscal year starts July 1.

Standardization is being approached through methods of identification of species, determination of color strength and determination of quality. Other problems, such as a method of assuring matching of colors in textiles, are to be taken up.

A report on dye standardization work at the bureau was submitted June 1 by Dr. C. E. Waters, chief of the Chemical Division, and W. D. Appel, dye specialist, to the main advisory committee of the Textile Division, composed of representatives of the larger textile trade associations. The advisory committee voted to request each textile trade association to appoint a committee of from one to three members to co-operate with the Bureau of Standards in its dye work.

I.C.C. Recommends Lower Rates on Acid and Feldspar

The Seaboard By-Product Coke Co. should be awarded reparation on various shipments of sulphuric acid from Grasselli and Brills to Seaboard, N. J., in the opinion of Burton Fuller, an Interstate Commerce Commission examiner. He finds that unreasonable rates were assessed on 39 carloads of sulphuric acid.

As a result of a complaint brought by the Ceramic Traffic Association, Paul O. Carter, an Interstate Commerce Commission examiner, has reported that the rates on feldspar from producing points in Maine, New Hampshire and Connecticut to New Jersey and Pennsylvania destinations are unreasonable. He suggests a series of lower rates on crude and ground feldspar which he asks the commission to prescribe for the future.

Prohibitive Tariff on Sulphur Proposed for Spain

The United States continues to supply a large proportion of the sulphur used in Spain, but an effort now is being made by the producers of sulphur in that country to secure a prohibitive tariff in the hope that their properties may be restored to their war-time activity. The proposal of the producers to place a high tariff on imported sulphur is actively opposed by the agricultural interests. The use of sulphur in connection with fertilizers and in the protection of grape vines makes it an important item in their costs.

Chilean Nitrate Sales Larger Than in Preceding Year

A survey of the Chilean nitrate trade as made by George A. Mackinson, consul at Valparaiso, states that the industry has almost completely recovered from the disastrous speculative slump of 1921. Sales effected during the first three-quarters of the present nitrate year, which began on July 1, total 21,851,078 metric quintals. This is only 15 per cent less than the quantity sold in the same nine-month period during prosperous war years and represents nearly triple the quantity disposed of during the first three-quarters of the past nitrate year.

March sales announced by the Producers' Association amounted to 1,966,331 metric quintals, as compared with 1,685,403 quintals in February and 1,960,742 in January. Sales effected by the association up to the end of March totaled 19,655,346 metric quintals, while "outside" sales, including 1,010,084 quintals credited to the two American companies, amounted to 2,133,762 metric quintals. The delivery dates of the association sales are as follows:

Month of Delivery 1922	For Export Metric Quintals	For Consumption Metric Quintals	Total Metric Quintals
July	2,407,565	1,016	2,408,581
August	1,639,599	7,586	1,647,185
September	1,809,657	9,428	1,819,080
October	1,991,361	17,289	2,008,655
November	1,618,407	5,042	1,623,449
December	109,798	1,609	111,407
1923			
January	1,977,716	508	1,978,224
February	2,701,970	3,058	2,705,028
March	2,051,595	2,032	2,053,627
April	611,124	508	611,632
May	1,016	....	1,016
June	2,687,456		2,687,456
Total	19,607,264	48,076	19,655,340

The March production of the fifty-nine plants now working amounted to 1,452,644 metric quintals—an increase of 733,031 quintals over the output of the thirty-one plants operating during the corresponding month of 1922.

Exports from the various ports of Chile during the past month totaled 2,226,017 metric quintals, as compared with 2,705,979 quintals in February and 2,225,139 quintals in January. Total exports for the first 3 months of the previous year amounted to only 1,036,480 metric quintals. Approximately 50 per cent of the 1923 exports has gone to the United States.

Stocks on the coast are being steadily reduced and at the close of the month amounted to less than 10,000,000 metric quintals, as compared with 15,713,140 at the end of the third quarter of the last nitrate year.

Tankage Held Dutiable

The claim of Gallagher & Ascher, of Chicago, for the free entrance of tankage has been overruled by the U. S. General Appraisers. Their decision is that it is dutiable at 10 per cent ad valorem as waste, not specifically provided for, under paragraph 384 of the tariff act.

Chemical Foundation Has Peaceful Week

The past week has been very quiet in the courtroom at Wilmington, Del., as far as the government's suit against the Chemical Foundation has been concerned. An adjournment was declared on June 15 for a week. Thus both sides gained an opportunity to catch second wind. The defence, with William D. Guthrie and Isador J. Kresel as leading attorneys, is expected to open its side of the case within a few days. Up to the present writing they have held the floor of the court only long enough to carry out their examination of the witnesses presented by the government. It is thought in some quarters that the entire case of the defence will be presented before dismissal is asked for. That the asking of such dismissal is regarded as likely by the court is evident from Judge Morris' question addressed to Kresel as to whether he might not take this step.

As the case stands, practically none of the evidence introduced by Colonel Anderson, attorney for the government, is held to be directly applicable. Although it is not understood at the time of going to press that Judge Morris has announced a definite decision to that effect, it is known that he has frequently questioned the right of the court to pass on acts of executive discretion carried out by the President.

The question of recompense is in dispute. The government's contention that $250,000 was entirely inadequate payment for the 4,800 patents is met by the argument of the defence that while the sum paid was not extremely high, still the Foundation has made use of these patents for the greatest good of the people and the industry at large.

Chemists Achieve New Victory Over Disease

The economic development of Africa has been greatly hindered by the prevalence there of sleeping sickness. A new compound developed by the Rockefeller Institute has recently been used successfully in combating this disease. Experiments covering a period of nearly 10 years have been required to develop the compound, which is the sodium salt of N-phenylglycineamide-para-arsenic acid. The *Journal* of the American Medical Association in a recent number outlines the history of the new drug.

Sicily Increases Exports of Sulphur Oil

The United States is taking more and more of Sicily's sulphur oil. During the first 3 months in 1923 exports to the United States from that island aggregated 1,280,011 lb. The Sicilians are in a position to offer particularly low prices on sulphur oil from the fact that it is obtained from treating the carbonate of sulphur after it has been used in extracting the residue of oil from olive pulp.

Canada Likes Idea of City Coke Plants

To Make an Extensive Survey of the Possibilities of Domestic Heating With Byproduct Coke

The possibilities of coking bituminous coal for domestic heating in Canada and some idea of the plans that are likely to materialize in that respect very shortly are given in the following extracts from the interim report of the Dominion Fuel Board, which has just been tabled in the House of Commons at Ottawa:

"The board is convinced of the importance of an investigation into the feasibility of establishing byproduct recovery coking plants in the larger centers of population. Not only are there the Nova Scotia and New Brunswick coals to draw upon but, as stated before, there are immense reserves of United States bituminous coal that could be imported for coking. Briefly, the plan would be to establish coking plants at large well-situated centers of population like Montreal and Toronto, where the coke could be manufactured and shipped to tributary territory, and the gas used at the point of manufacture.

"Other valuable byproducts, such as tar, ammonium sulphate and benzol, are obtained, and the success of such an industry depends on the disposal of these.

"The chairman of the board investigated a plant established by the cities of St. Paul and Minneapolis for the manufacture of this coke, and found that not only were the two cities above referred to being supplied but that shipments were being made to Winnipeg. More recent investigation by the board in other part of the United States, where coke is being manufactured and used for domestic purposes, have confirmed the conclusion that this should be a very fruitful field for further investigation. The board considers that developments in this connection hold out so much promise that it has by resolution placed on record its decision to employ a competent expert to report upon the matter.

Commerce Department Catches Up on Import Statistics

The Department of Commerce has issued an announcement to the effect that the delays in compilation of the import and export statistics due to the greatly increased number of items required under the last tariff act have been overcome, and the import and the export figures are again issued coincidently at the usual time.

Manila Using More Paint

A recent cable from Trade Commissioner J. A. Fowler of Manila says that paint sales in that section show still further improvement. The market for red lead remains slow. The overstocked condition of the white-lead market has been relieved and sales continue fair.

Advocate Lower Freight Rate on Nitrate of Soda

The New Orleans Joint Traffic Bureau has attacked the freight rate applicable to nitrate of soda. A large portion of the nitrate of soda imported comes through the port of New Orleans. The New Orleans Traffic Bureau contends that a reasonable rate on nitrate of soda cannot exceed the rates applying on other fertilizers. In its arguments before the Interstate Commerce Commission, it attempts to establish that nitrate of soda is not an explosive and that fires that have resulted from the shipping of nitrate of soda have been negligible. It admits that twenty-four fires during the 11-year period from 1910 to 1921 have resulted from the shipping of that commodity, but that the resulting losses did not exceed $60,000. For that reason it is contended that the fire hazard is negligible. It also is argued that the railroads themselves would benefit by charging fertilizer rates on nitrate of soda, since it would stimulate its use, thereby increasing the yield of crops, which in turn would augment the tonnage available to the railroads.

Vegetable Oil Residues Used in Netherlands Soap Trade

Vegetable oil foots and other byproducts of the refining of vegetable oils are being extensively used at present by the large soap and candle factories in the Netherlands.

The soap and candle factories are using comparatively little of the inedible tallows and inedible grease stearine which is usually the first choice in soap and candle materials. Vegetable oil residues, together with fish and whale oil, are under present conditions receiving most attention from Dutch users.

The candle and soap factories in the Netherlands, particularly the former, have very modern plants and are equipped to acidulate and concentrate these oily byproducts. The grease or acid oils resulting from this process are split again for the separation of glycerine and fatty acids, which are distilled once, twice, or three times, depending on the quality of the material and the lightness of color desired in the distilled fatty acid. The refined vegetable, whale and fish oils are also hydrogenated and used in the manufacture of soap. At present the candle factories are using to some extent a combination of any or all of these hydrogenated oils with paraffine.

German Textile Industry Quiet

The depression in the retail and wholesale textile trade of Germany which began last February has shown improvement recently, according to a report from Dresden. However, the general condition of the textile industry in that country is described as uncertain. This is shown by the refusal of buyers to enter into obligations for the future.

Casein May Be First of Chemical Items for Tariff Hearing

Investigation of This Material Has Progressed Further Than Other Chemicals Under Consideration

CASEIN probably will be the first of the seven chemical items being investigated by the Tariff Commission with a view to possible changes in duty under the flexible tariff to be docketed for public hearing. The investigation into costs of production of casein at least has progressed further than that into any of the other items of the chemical schedule into which inquiries are being made.

F. W. McSparren, one of the Tariff Commission's chemical experts, has returned from Argentina, where he spent 6 weeks investigating the costs of producing casein, regarding which coated paper manufacturers of the United States have applied to the commission for a reduction in duty. Carl R. DeLong, chief of the Chemical Section, and two assistants conducted investigations into this product in Europe at the outset of their work on a number of chemical items there. Mr. DeLong will return in July with the data secured up to the time of his departure, which are expected to include all of those relating to casein. The inquiry into costs at domestic plants is well in hand.

No date has been fixed for a public hearing on casein, but it is probable that the subject will be considered by the commissioners soon. Thirty days' notice must be given of the hearing date.

C. H. Penning, a chemist of the Tariff Commission, is visiting domestic plants securing costs of logwood extract and barium dioxide in connection with the commission's inquiries into these items. Costs of production of logwood extract in Haiti have been secured, but are to be checked by a personal visit of an agent of the commission, while figures from Europe also will be secured before the hearing on this item is set.

German Plants Coming Here

German patents and processes applied by German workmen, mechanics and chemists may be used for the development of foreign-owned factories in this country. Three prominent German bankers arrived in this country last week, who, according to press dispatches, intend to manufacture cosmetics, mouth wash, soaps, toothpaste and chemical products in the United States.

The three bankers in question are Rudolf Rosenheim, of Düsseldorf, formerly a chief executive of the banking firm of Fester & Co., a Stinnes concern; Martin Sternberg, of Sternberg & Co., a bank having headquarters in Amsterdam, and Curt Sorbeim, director of the Commercial and Private Bank in Berlin. These men have intimated to a press representative that they will not seek the support of American bankers.

American Progress to Be Reflected in Exposition

The greater number of American chemicals and the fewer foreign items being used in the United States as compared with conditions a year ago will undoubtedly be reflected in the Chemical Exposition. Early estimates indicate that the line of "Made in America" chemicals which will be shown this year will cover a broader field than even during the most active period of the war. Equipment developments in America during the year have not been affected to such a degree as the chemicals by changed conditions in Europe, although the strides forward, which will be exhibited in September, have been large.

During June the demand for chemicals in the United States has been smaller and permitted the gradual accumulation of imported stocks here, although in practically all cases American goods are commanding a premium in price over the foreign. At the exposition in September, a birdseye view of the recent developments in the American industry which have made this condition possible, considered impossible 10 years ago by all the leading authorities, will be presented. The spirit of the new chemical America will be epitomized in the 1923 show.

Paint Trade of Yucatan

There are no paint manufacturers in Yucatan, and the paints and varnishes used there are almost exclusively of American origin. Oil paints are used for interior and exterior finishes in both the better stone and wood houses. Water paints have a comparatively large field owing to their cheapness, ease of application and adaptability to stone interior and exterior walls.

American weights and measures are used, except in the case of products sold in bulk, such as powder, oil and other like commodities, which employ the metric system. Tins of a gallon and less are desirable for the general retail trade. There is no preference as to their shape. Containers are of the same type as those used in the United States, but the lettering should be in Spanish. No complaint has been made as to rusting of tins or other deterioration. Good packing, including waterproof lining, is desirable to withstand rough handling in the port of Progreso, and also to avoid injury to tins through accidental wetting with salt water in the unprotected harbor. There are no government regulations as to the composition and marking of paints and varnishes.

Trade Notes

The Lyon Engineering & Construction Co., 225 Fifth Ave., New York, has issued schedules in bankruptcy with liabilities placed $16,447 and assets $26,000.

H. D. Whittlesey, vice-president and director of sales of Sherwin-Williams Co., was elected to the office of vice-president of the National Association of Sales Managers.

Production of olive oil in Italy in 1922-23 amounted to 2,891,140 quintals. Average production of oil per 100 kilos of olives was 19.18 kilos.

While the hog industry in Denmark and Poland shows complete recovery, the number of hogs in Germany is approximately 1,000,000 less than it was a year ago and about 33 per cent below the pre-war figure.

Potash salts to the extent of 4,616 tons were produced during March at the mine at Kalusz, Galician Poland.

Charles M. Mason and Henry M. Miner have been appointed temporary receivers for Wood Oils, Inc., Blanchard St., Newark, N. J. The company specializes in the production of linseed oil, with main plant at Sidell, La. New York offices are at 19 West 44th St. Edmund W. Brown is president, and Frederick T. Snyder secretary and treasurer.

Cottonseed meal trading in spot and futures will be resumed by the Memphis Merchants' Exchange Clearing Association, beginning July 1.

The annual meeting of the International Association of Seed Crushers was held in Scheveningen, Holland, June 15 and 16.

Fertilizer Men to Gather at Storrs

Round-table discussion of fertilizer problems, especially as met in New England, is to be carried out at the second annual conference of fertilizer manufacturers and dealers. This meeting is to be held at the Connecticut Agricultural College, Storrs, Conn. Accommodations for those who spend July 11 and 12 at Storrs, the two days of the meeting, may be obtained in the quarters of the college.

The program as officially announced includes the following subjects: "Fertilizer Problems of Connecticut," E. H. Jenkins; "Significance of a Survey of Connecticut Soil Possibilities," W. L. Slate; "Economic Use of Commercial Fertilizers," J. G. Lipman; "How Can Scientific Workers and Fertilizer Men Co-operate Better to Serve the Farmer?" S. B. Haskell; "How the Farmer Looks at the Fertilizer Problem and How He Should View It," A. W. Manchester; "Field Crop Fertility Problems," J. S. Owens; "Present-Day Problems of the Industry," speaker to be announced.

Ruhr Licenses Must Be Applied For Before July 1

The State Department has received notice from the Rhineland High Commission that American firms planning to ship goods from occupied Germany must make application for export licenses before July 1. Firms wishing to ship goods into the Ruhr also must make application for license by the end of June.

The decision of the High Commission states: "The interallied authorities may authorize the foreign seller to take the place in the application for the importation license of the defaulting German importer, in cases where the sale is the object of an order placed before Feb. 1, 1923, and more particularly where the goods have been totally or partly paid for. In cases where one of the above-mentioned conditions cannot be filled the interallied authorities may authorize special importation by way of exception."

In order to enjoy the benefit of the measures indicated the foreign seller must address an application to the interallied services concerned, as follows:

To the executive committee of licenses of the High Commission for merchandise consigned to firms located in the occupied territory, with the exception of those located at the Düsseldorf and Duisburg bridgehead and the basin of the occupied Ruhr district.

To the license department of the Factory and Mine Control Mission at Essen for merchandise consigned to firms located at the Düsseldorf and Duisburg bridgehead and in the basin of the occupied Ruhr district.

The application must be accompanied by a certificate vouching for the date of the order and the total or partial payment, if any, of the goods before February 1.

This certificate must be issued:

(*a*) If the seller belongs to one of the nations represented in the High Commission, or the interallied license department, by the representative of this nation therein.

(*b*) If the seller does not belong to one of the nations represented in the High Commission, or the interallied license department, by the diplomatic representative of his government or one of the governments represented in the interallied department.

The time in which applications will be received expires June 30, 1923, inclusive.

Engineering Educators Convene at Cornell

Three Hundred Leaders Gather to Decide Lines of Endeavor

Engineering leadership and educational research were leading topics at the annual meeting of the Society for the Promotion of Engineering Education at Ithaca, N. Y., on June 20 to 23. More than three hundred leading educators from all sections expressed an enthusiastic desire to carry forward the educational research project formulated by 2 years' work of the committee of investigation and co-ordination. This calls for the investigation of the objects of engineering education and the best curriculum to attain the desired ends. A director is to be appointed, with an advisory board, and Dr. H. S. Pritchett of the Carnegie Corporation has recommended to his directors and to other foundations the expenditure of $108,000. Action is to be taken immediately by appointing a faculty committee at each school to co-operate with the director.

At the opening meeting on Wednesday afternoon Dean D. S. Kimball gave a notable address on training for leadership. He said that precedents were lacking whereby legal leadership in the nation could codify past experiences and that the present epoch utilized pure and applied science so greatly that the engineer was needed. The fundamental curriculum, he thought, should not be changed, as such a practice would undermine the standing of the engineer which has been built up over many years. Hope for solving present problems lies in the application of engineering principles by the industrially intelligent, and the present era calls for universal well-being, not private, state or corporate profits. In the opinion of Dean Kimball, the chief trouble with the present curricula as regards training leaders is that they afford no historical background. There is also an insufficient number of inspiring teachers.

Excellent arrangements were made for caring for visitors in the Cornell University building, and many entertainment features were provided for the visiting ladies. On Wednesday night President Farrand of the university, welcomed the members of the society, and President C. F. Scott of the society responded, after which an informal reception was held.

Financial Notes

The Joseph Dixon Crucible Co. has declared a regular quarterly dividend of 2 per cent, payable June 30.

Darling & Co., of Chicago, have made a bond issue loan of $1,250,000 for 20 years at 6½ per cent, for defraying construction expenses of the new grease-distillation plant at 46th and Cook Sts., Chicago.

The Ohio Leather Co., of Youngstown, O., has declared a quarterly dividend of 2 per cent on its preferred stock. This is the first dividend to be declared on the preferred stock since the financial reorganization of the company.

The A. E. Staley Mfg. Co., Decatur, Ill., manufacturer of corn products, is disposing of a bond issue of $3,000,000, a portion of the proceeds to be used for general expansion and financing. Plans are now nearing completion for the construction of a 3-story addition to the local grinding and refining plant. A. E. Staley is president.

The Pennsylvania Salt Mfg. Co. has declared a regular quarterly dividend of $1.25. An extra dividend of 50c. was declared 3 months ago.

For the first 3 months of the current year sales made by the Atlas Powder Co. were $4,901,751, an increase of about 40 per cent over same period of 1922, when sales were $3,570,833. It is estimated that business for 1923 will total more than $20,000,000, compared with $16,723,735 in 1922.

The Certain-teed Products Co. has declared regular quarterly dividends of 1¾ per cent on first and second preferred stocks, both payable July 1 to stock of record June 19.

The American Cyanamid Co. declared an initial dividend of 1 per cent on the common stock and the regular quarterly dividend of 1½ per cent on preferred stock, both payable July 2 to stock of record June 26.

Earnings of Corn Products Refining Co. for 6 months ended June 30 are unofficially reported as showing substantial improvement over those of first half of 1922. Plants are grinding at approximately 68 per cent of capacity.

Coke Production Rising

Coke production figures for May, just published by the United States Geological Survey, indicate that during that month 3,328,000 net tons were pushed from byproduct ovens. This was an increase of 122,300 tons, or 3.8 per cent, over April. Beehive production also increased, the net output amounting to 1,829,000 tons. Sixty-three of the sixty-nine plants in the country are producing at present.

Babassu Nuts in Demand

Advices from Brazil state that there is great activity in the babassu market in the northern states of Maranhao and Piauhy. Exports of babassu nuts from Maranhao during the first 4 months of 1923 amounted to 8,500 tons, as compared with 2,000 tons during the corresponding period of 1922. The babassu nut produces a vegetable oil very similar to coconut oil but somewhat higher in free fatty acid.

Oil Men Will Meet in Chicago

At an executive meeting of the Oil Men's Association, held in Chicago last week, it was decided to hold the annual convention of the association at the Congress Hotel, Chicago, on Oct. 2 and 3. Walter G. Willard, formerly field secretary of the Western Petroleum Refiners Association, was chosen to succeed Melville C. Hill as secretary of the organization. Mr. Hill recently tendered his resignation in order to return to the practice of law. The change becomes effective July 1.

Facts and Figures That Influence Trade in Chemical Products

Market Conditions

Current Prices Imports and Exports The Trend of Business

Consumers and Distributors Restrict Operations in Chemicals

Speculative Buying of Minor Importance and Manufacturing Trades Are Interested Only in Nearby Positions

THE index number shows a material decline for the week. This represents a lower price level for some chemicals, but allied products, such as cottonseed oil, linseed oil and glycerine had considerable to do in bringing down the total from the level of the preceding week.

Some of the large consuming trades are not working at capacity and this seasonable condition is felt in a diminished call for raw materials. The movement of important chemicals against contracts is very good, in fact June deliveries in some cases are larger than the totals for May. It is in new business for home and for export that the falling off in demand is most noticeable. This is especially true with reference to forward positions, as present trading is almost entirely for spot and nearby goods.

One of important features noted in the market was an announcement by a leading alkali producer that prices for soda ash and caustic soda would be on a flat basis. For many years it has been the universal custom to quote these chemicals on a basis price—48 per cent Na_2O for soda ash and 60 per cent Na_2O for caustic soda. The flat quotation simplifies quotations and they will be more readily understood by buyers. Attempts have been made, at intervals, to depart from the basis method of quoting, but nothing definite resulted until the present change was adopted.

Price changes were in evidence in numerous cases. Calcium arsenate, which is one of the items followed very closely at present, was disturbed by reports of offerings considerably below the levels previously held. This was in sharp contrast to views of sellers who had expected an increased demand and a hardening in prices. However, the low priced offerings were said to be restricted to a few cars and it is still too early to express a decided opinion on values for delivery over the next month. Arsenic was lower for distant positions with practically no change on spot. Nitrite of soda was easier and the same was true of nitrate of soda. Imported cyanide of soda weakened likewise. Low-priced offerings of imported copper sulphate were less in evidence and the market was firmer. Permanganate of potash also was steadier.

Acetic Acid—Buying has been active enough to take up the output of some sellers and stocks of the lower tests are reported to be light. Production has not been at full capacity and this has been a factor in holding supplies on a parity with consuming needs. Prices have undergone no change in the period and are quoted at \$3.38@\$3.63 for 28 per cent; \$5.48@\$5.75 for 80 per cent; and \$12@\$12.75 for glacial.

Citric Acid—Sales of imported were reported at 51c. per lb. and the asking prices ranged up to 52c. per lb. Advices from primary markets abroad indicate firm conditions there and shipment prices are about on a parity with the spot market. Domestic acid is still quoted at 49@50c. per lb., but the sold up condition of some producers makes their quotations purely nominal.

Caustic Soda and Soda Ash Now Quoted on Flat Basis—Calcium Arsenate Easier—Arsenic Lower on Futures—Metal Salts Easy—Nitrite of Soda Declines—Imported Copper Sulphate Firmer—Permanganate of Potash Steadier—Prussiates Dull and Weak

Formic Acid—Domestic grades are not prominent on the market as the quoted prices of 16@17c. per lb. are too high to interest buyers. Domestic production is said to be greatly curtailed owing to the low prices at which foreign material has been offered. Current quotations for imported are 12@14c. per lb. Demand has shown some improvement.

Muriatic Acid—The market is in a very firm position with some sellers using their output to take care of old orders. Others have only small surplus stocks. Most consumers are covered by contracts and spot business is mainly for moderate sized lots. Prices are repeated at 90c.@\$1 per 100 lb. for 18 deg., and \$1.75@\$2 for 22 deg.

Nitric Acid—Under a quiet trading movement the market has worked into an easy position and while no open change in prices has been announced there are reports that quotations can be shaded. Asking prices are on a basis of \$4.50@\$5 per 100 lb. for 36 deg.; \$4.75@\$5.25 for 38 deg., and \$5.25@\$5.50 for 42 deg.

Oxalic Acid—The market has been easier and importers were offering freely at 13c. per lb. Domestic material also was easier and 13c. per lb. at works was the asking price. Demand is fair for small lots. Domestic production is said to be on a smaller scale.

Sulphuric Acid—There is not the stringency in supplies which characterized the market recently. Lessened demand has enabled producers to accumulate small stocks but good deliveries continue on contracts and values are holding on a steady level. Quotations are \$15@\$16 per ton for 66 deg. in tanks at works.

Tartaric Acid—Buying has failed to gain in volume to the extent importers had expected and prices are easy. Bids under quoted price levels are said to have been accepted. Quotations for imported are 35½@36c. per lb. No change has been made in domestic acid and sales are said to be going through at 37½c. per lb.

Potash

Bichromate of Potash—The quiet position of the textile and leather trades has been reflected in a slower demand for bichromate. Most first hands are holding prices at 11¼@11½c. per lb. but reports are heard to the effect that sales have been made at 11c. per lb. and it is said this is the actual trading level.

Carbonate of Potash—While some grades are in light supply, there is sufficient material on hand to fill buyers' wants and total sales are said to be very small. Only small lots are changing hands and with buyers out of the market, prices are not inclined to advance. Quotations are 6½@6¾c. per lb. for 80-85 per cent; 7½@7¾c. per lb. for hydrated 80-85 per cent, and 7@7½c. per lb. for 96-98 per cent.

Caustic Potash—Some sellers are holding prices on a firm basis and report a strong market for imported. Buying, however, has been quiet and this has caused some holders to grant concessions and 7¾c. per lb. is still quoted. Asking prices range up to 8c. per lb. with grade and seller as the reasons for the difference in quotations.

Permanganate of Potash—Sales of odd lots were put through at 16¾c. per lb. Distressed lots have been pretty well taken from the market and toward the close 17c. per lb. was the lowest price at which many holders would accept orders. Shipment prices are reported to be above the spot price and

this had some influence in steadying values.

Prussiate of Potash—Continued slow demand is reported and buyers look for concessions before taking on stocks. Views of sellers vary, but 31c. per lb. is still given as a trading basis despite the fact that others are quoting 34c. per lb. as their inside price.

Sodas

Bichromate of Soda—Withdrawals against existing orders have been less persistent and this is especially true with reference to consumers in the leather industry. New business is largely restricted to small lots. Occasional lots are offered in the spot market as low as 8½c. per lb. but first hands are maintaining quotations at 8½c. per lb. at works, with the usual premiums for smaller amounts.

Caustic Soda—This market has been featured by an announcement by one of the largest sellers that quotations hereafter would be on a flat basis. This supersedes the method in vogue for many years of quoting on basis 60 per cent. The new method of quoting is said to meet with favor of buyers as more or less confusion has arisen at times because of the basis price in quoting. All sellers have not adopted the flat quotation method but it is thought that the lead as set by one of the largest factors will be followed by others. The prices as now quoted are: 76 per cent solid caustic soda in 700-lb. drums, \$3.16½ per 100 lb.; 76 per cent ground caustic soda in 475-lb. drums, \$3.60 per 100 lb.; 575-lb. bbl., \$3.85 per 100 lb.; 76 per cent flake caustic soda in 400-lb. drums, \$3.00 per 100 lb., 525-lb. bbl., \$3.85 per 100 lb.

Cyanide of Soda—Some nearby material was available at 20c. per lb. This price was for imported and shows an easier tone due to eagerness of sellers to effect sales. Demand has been rather quiet although some sellers of domestic report a good call for their product on which they quote 22@23c. per lb.

Nitrate of Soda—The spot market has been easy for some time. It is natural to look for a falling off in buying at this time of year and prices fluctuate according as stocks are in strong or weak hands. Recently spot offerings have been pressed for sale. The asking price is \$2.45@\$2.50 per 100 lb., but sales have been made under the inside figure and the market has not improved enough to hold prices steady and it is a question how much under \$2.45 per 100 lb. sellers will go in order to close transactions. Some shading of the schedule price also has been noted in the case of futures especially for shipments through December.

Nitrite of Soda—Selling competition has been very keen with imported grades leading in price declines. Sellers of domestic generally have met the low prices quoted and have openly quoted at 7½c. per lb. works. Imported offerings were quoted at 7¼@7½c. per lb., and on this basis the delivered price to some consuming centers favors the home-made product.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	175.39
Last week	177.88
June, 1918	272.00
June, 1919	229.00
June, 1920	2?4.00
June, 1921	1?7.00
June, 1922	157.00

The index number went off to the extent of 249 points. Lower prices for cottonseed and linseed oils, together with a decline in glycerine, were important factors.

Prussiate of Soda—Unsold stocks of imported appear to be ample and sellers on the other side are reported to be eager to make regular shipments to this market. This keeps the tone easy and it is difficult to give any price as representing sellers' views. In most quarters 15c. per lb. is said to be an inside price. Domestic grades are quoted at 16c. per lb. but are receiving scarcely any attention.

Soda Ash—As in the case of caustic soda, the most important occurrence in the market was the abolition of the basis price and the establishing of flat quotations by one of the largest sellers. Flat quotations are: 58 per cent light soda ash in bulk, \$1.33 per 100 lb.; 300-lb. bags, \$1.45 per 100 lb.; 150-lb. bags, \$1.50 per 100 lb.; barrels, \$1.69 per 100 lb.; 58 per cent dustless dense soda ash in bulk, \$1.42 per 100 lb.; 430-lb. bags, \$1.51 per 100 lb.; 430-lb. bbl., \$1.95 per 100 lb.

Miscellaneous Chemicals

Arsenic—The spot market shows very little change. Demand while improving a little is not heavy for this season and under the circumstances it is difficult to maintain higher price levels, although sellers seem to be more reserved. Prices heard ranged from 13½c. to 15c. per lb. depending on sellers. Futures, however, were easier and as low as 10c. per lb. was heard for the last half of the year.

Calcium Arsenate—While a better tone is noted in the market as a result of some improvement in demand, it is stated that orders are not coming to hand in volume sufficient to place the market in an active position. Just at present the main feature is furnished by the irregularity of prices.

Quotations heard have ranged from 12c. per lb. to 17½c. per lb. The 12c. quotation appears to have been a bona fide offer on the part of a seller who had a limited amount to sell but it is generally discredited as a real indication of the prevailing market price. However, it is stated that Southern buyers can shade 14c. per lb. delivered. Most sellers give 16c. per lb. as the open quotation. Impartial views hold prices are a matter of private negotiation between the 14c. and 16c. levels with this condition depending on the buying movement to bring about a decided price trend.

Copper Sulphate—Several orders for imported material at old prices could not be filled. At the close there were buyers of foreign sulphate at 4⅞c. per lb., with sellers apparently firm at 5c. on spot and nearby parcels. The season of increased consumption is near at hand and this tends to support the market. Domestic material was unsettled in some directions because of the foreign competition. Prices heard ranged from 5⅛@5⅜c. per lb.

Formaldehyde—Producers generally maintained prices on the 15c. basis, but comparatively little business was put through. Scattered lots could have been picked up through second-hand channels at 14½c. per lb.

Tin Oxide—The market for the metal was easy and this naturally led to some talk of lower prices for tin oxide. But up to the close operators continued to quote the market at 48c. per lb. Trading was confined to small lots only.

Sal Ammoniac—There were offerings of the imported material at 6½c. per lb. The market was quiet and barely steady. Domestic gray, in casks, held at 8c., with the white at 7½c. per lb.

Barium Chloride — Offerings from abroad have increased and this unsettled prices here. There were offerings at \$80@\$82 per ton, carload lots.

Fusel Oil—The market was virtually bare of supplies and dealers refused to name a flat price. A little trading in crude developed recently around \$3.75 per gal. Several small shipments arrived from abroad during the week.

Alcohol

While trading was conducted along routine lines only, producers expect that business will soon pick up, and, with stocks not burdensome, prices were firmly maintained. In denatured alcohol producers offered the special No. 1 formula on the basis of 35c. per gal., in drums, and 41c. per gal., in barrels, carload lots. Ethyl spirits, U.S.P., 190 proof, held at \$4.70@\$4.75 per gal., in barrels. Butyl spirits closed unchanged at 26@27c. per gal. With production curtailed over the summer months, the market for methanol ruled steady, first-hands quoting \$1.18 per gal. on the 95 per cent, and \$1.20 per gal. on the 97 per cent grade.

Italy Eases Export Bans

Export restrictions governing Italian products have been considerably relaxed since June 3, so that licenses are now required for only the following commodities: Hemp and flax waste, rags, excluding tow; wooden railroad cross ties; iron ore, except pyrites; copper, brass and bronze scrap, except turnings; iron and steel scraps; wheat, oats, and uncleaned rice; cattle and fresh beef; asses; bones and metallic money. This information is contained in a report just received by cable from Commercial Attaché N. C. McLean.

For some time quite a number of commodities have been on the list of goods which are prohibited from exportation.

Coal-Tar Products

Benzene Unsettled in Dull Market—Synthetic Phenol Offerings Increase—Naphthalene Easier—Solvents Firm

PRODUCERS of coal-tar byproducts reported a quiet week. With the exception of solvent naphtha the market seemed to favor buyers. An easier undertone prevailed in benzene, phenol, naphthalene and the salicylates. First-hands announced no price changes, but admitted that considerable shading was possible in outside channels. Scattered lots of benzene sold at concessions, and with no improvement in the motor fuel situation, either here or abroad, supplies on hand were considered more than ample for current needs. Offerings of synthetic phenol are increasing, but the output has not yet reached the stage where producers are willing to meet the views of larger consumers, with the result that virtually no round-lot transactions are being placed. There were willing sellers of synthetic phenol for future delivery at 40c. per lb. "Regular" buyers could have obtained the natural product around 30c. per lb. deferred delivery. On spot resale parcels were offered at prices ranging from 42c. to 50c. per lb., the top figure obtaining on small lots. Crude naphthalene was offered for shipment from abroad at concessions, but so far as could be learned no buying interest developed. Refined naphthalene on spot was unsettled and slightly lower prices prevailed on odd-lot transactions. Solvent naphthas were in scanty supply and first-hands reported the market as firm with prices more or less nominal. Pure zylene was in moderate demand, and, with stocks on spot limited, prices were firmly maintained.

Alpha-Naphthylamine — The market was barely steady, but most producers held out for 35c. per lb., immediate shipment from works. Demand was slow.

Aniline Oil—Business was confined chiefly to small lots and it was possible to pick up supplies involving less than carload lots on the 16c. per lb. basis.

Benzoic Acid—Anticipating seasonable activity in this commodity, traders were disposed to ask higher prices. The U.S.P. grade on spot held at 77@80c. per lb., with forward material available at 72@75c. per lb., as to quantity and seller.

Benzene — The market developed weakness in outside channels, but leading producers refused to meet this competition. The demand has been disappointing and with no change for the better in the motor fuel situation some traders were not disposed to hold on to supplies and stood ready to cut prices in order to interest consumers. The 90 per cent grade, so far as leading producers were concerned, held at 25c. per gal., tank cars, f.o.b. works, with the pure at 27c. per gal., tank cars, f.o.b. works. Advices from Manchester, England, report quiet trading in benzene, but the price, while barely steady, settled around 1s. 7d. per gal.

Cresylic Acid—Prices named toward the close, on imported material, ranged from $1.05@$1.15 per gal., according to grade and seller. Business was neglected and the undertone easy. Offerings from domestic sources, for nearby delivery, have increased of late, but producers announced no price changes.

Naphthalene—Scattered parcels of flake sold down to 7¾c. per lb., which compares with 8c. a week ago. The demand was not sufficient to steady the market. Crude to import was offered at 2½@3¼c. per lb., the price varying according to the seller and specifications. London advices, under recent date, indicate that the market in the United Kingdom has eased off, with sellers of crude at £7@£12 per ton, the inside figure prevailing on rather low-grade material.

Phenol—With offerings of the synthetic product increasing, sentiment favored buyers. For spot material most traders were asking from 48@50c. per lb., but several lots came on the market at concessions and prices at the close were little more than nominal. During the week actual offerings of resale material were heard of at 42c. Second-half of 1923 business could have been negotiated at 40c. per lb. Producers of the natural product refused to name a flat price, but intimated that on contract regular customers might obtain supplies around 30c. per lb.

Solvent Naphtha—Demand for this material was good and with production sold well ahead the market ruled firm. Leading producers held out for 27c. per gal., tank car basis, forward delivery, f.o.b. works.

Effects of Borax on Plant Growth

After exhaustive experiments, the U. S. Department of Agriculture claims to have proved that as little as 4 lb. of borax to the acre is detrimental to plant growth. In some instances, however, no detrimental affect was noted until borax had been applied to the extent of 20 lb. to the acre. The lengthy period of experimental work was made necessary because it damaged crops during the war, when a potash salt containing borax was used.

The experiments show that the potato can tolerate a greater quantity of borax than plants such as corn and beans, which are injured by comparatively small quantities of borax. The degree of injury, however, depends more than anything else upon the depth and distribution of rainfall.

Standard Test Requested for Coal-Tar Distillates

Owing to confusion which has arisen because of different methods of testing the quantity of distillate in certain coal-tar products, the Customs Division of the Treasury Department will ask the United States Bureau of Standards to evolve a standard test, which will be adopted uniformly by the customs service.

The issue has been brought to the front by the complaint of an importer who brought two importations of the same product through two different ports, New York and Philadelphia. At New York, the test given at the chemical laboratory of the Customs Division showed that the product was entitled to free entry under paragraph 1549 of the 1922 tariff act. The test by the customs chemist at Philadelphia produced a different result, and there the product was declared dutiable under paragraph 27 of the act, at 55 per cent ad valorem, American selling price, and 7c. per lb. A sample of the identical lot tested at Philadelphia was submitted the Chemical Division of the Bureau of Standards, and a still different result was obtained there, placing the product practically on the borderline between free and dutiable. In each case a different method of testing was used. Final liquidation of the importations has been held up pending further investigation by the Treasury officials.

Paragraph 27 declares duitable "all distillates of coal tar, blast-furnace tar, oil-gas tar, and water-gas tar, which on being subjected to distillation yield in the portion distilling below 190 deg. C. a quantity of tar acids equal to or more than 5 per centum of the original distillate or which on being subjected to distillation yield in the portion distilling below 215 deg. C. a quantity of tar acids equal to or more than 75 per centum of the original distillate."

Paragraph 1549 declares entitled to free entry these tars and "all other distillates of any of these tars which on being subjected to distillation yield in the portion distilling below 190 deg. C. a quantity of tar acids less than 5 per centum of the original distillate."

German Chemical Prices Firm

Chemical prices in Germany are regarded as showing remarkable firmness in the face of wild fluctuations in the mark and the rampant speculation which is honeycombing practically every German industry. It may be mentioned, however, that the stability of price apparently has not extended to the pharmaceuticals. The capital increases of the German chemical companies is proceeding merrily.

The fact that five months' dye quota has been taken at one fell swoop is expected to mean increased exports to the United States since the quantities are greater than can be digested at once in Europe.

Vegetable Oils and Fats

Cottonseed Oil Lower—Prompt Shipment Linseed Declines—Coconut Sells at 8¼c.—Soya Offered Freely

OFFERINGS of most oils increased, and with general unsettlement in speculative commodity markets, the undertone was easy and lower prices obtained for cottonseed, linseed, china wood, olive, oil foots and crude soya bean oil. The cottonseed statistics, which came out early last week, were regarded as bullish, but this did not inspire any confidence in the market. Lard was unsettled at the close, while in tallow the situation eased off somewhat on intimation that prospective buyers lowered their views.

Cottonseed Oil—Liquidation in the July option in the market for refined oil was the feature. The Bureau of Census report on cottonseed products revealed that 128,871 bbl. were consumed in May, a favorable showing considering the low position of competing fats. The visible supply on May 31 amounted to 627,000 bbl., against 707,000 bbl. on the corresponding date a year ago. (The report is reviewed elsewhere in this issue.) Speculative holdings of nearby oil in the contract market were larger than traders seemed willing to admit and fears for liberal tenders in July oil added to the unsettlement. There were numerous switches of July contracts to the September option. With cash trade slow refiners also were disposed to unload a little nearby oil. In the opinion of traders the speculative element will not operate on the long side in the old crop months, believing that the tight statistical situation has already been discounted. On the other hand the new crop is attracting widespread attention and, in the event of a 12,000,000 bale cotton crop, the sentiment at the close was rather bearish. Old crop crude was offered at 9⅛c. per lb., tank cars f.o.b. Texas, with buyers at 9c. per lb. Recent business in November forward was booked at 7c. per lb., f.o.b. Texas common points, about 50 tanks moving at this figure. Bleachable oil sold at 9⅜c. per lb., tank cars, f.o.b. Texas, immediate shipment. Lard compound was easier at 12⅜c. per lb., f.o.b. New York.

Linseed Oil—The seed markets eased off towards the close, and with cake higher, crushers appeared a little more anxious for business. But comparatively few inquiries came out as asking prices were considered too high, especially where September forward oil was concerned. Spot oil sold at $1.08 per gal., carload lots, cooperage included, with intimation in some quarters that this figure could be shaded on early July business. On second-half of July $1.05 represented the market, with August at $1.03, carload lots, cooperage included. The lowest price heard on August forward was $1 per gal. Consumers take the stand that September forward should be selling around 90c. per gal., based on prevailing prices for seed and cake. Foreign oil weakened on lack of buying interest from America. In London spot oil, loose, closed at 43s. 6d. per cwt. (112-lb.), which compares with 45s. 6d. per cwt. a week ago. Continental demand has been slack, soapers taking to cheaper fats. A fair increase in the United States flaxseed acreage is expected and from latest reports the crop is doing well. The Canadian acreage will not be much larger than last year, according to private advices. Indian offerings continue large. According to the final official estimate production for the 1922-23 season amounted to 21,280,000 bu., which compares with 17,360,000 bu. the previous season. Argentine shipments from January 1 to June 16 amounted to 33,248,000 bu., of which total 16,612,000 bu. were shipped to the United States. Linseed cake closed steady at $37 per ton, f.a.s. New York, which compares with $34 the recent low.

China Wood Oil—The undertone was easier on re-sale offerings. Spot material was available at 26c. per lb. August forward shipment from the Pacific coast, in sellers' tanks, was offered at 21c. per lb.

Coconut Oil—The sale of 5 cars of Ceylon type oil went through at 8¼c. per lb., f.o.b. New York. On the coast 1 car sold at 8¼c., immediate shipment. Copra was steady at 4⅝c. per lb., c.i.f. coast ports. England has been a buyer, supporting prices.

Olive Oil Foots—Spot prime green material sold at 7½@7⅝c. per lb. So far as quotations went holders were asking from 7⅞@8c. for spot.

Palm Oils—A distressed parcel of Lagos oil sold at 6⅞c. per lb. Lagos for import held around 7¼c., with Niger at 6⅞c. per lb., c.i.f. terms.

Soya Bean Oil—Prices weakened in all quarters because of the lack of buying interest. There were offerings at 9⅛c. coast and 9⅛c. New York, sellers' tanks, nearby positions, duty paid.

Tallow and Greases—Last trading in extra tallow went through at 7¼c. per lb., but just before the close the undertone was easier, with offerings at 7⅛c. per lb. Yellow grease was offered at 6⅛c. per lb., with no buyers. Oleo stearine closed at 8⅞c. asked.

Miscellaneous Materials

Casein—Imported material was offered freely, and, with no improvement in the demand, prices presented a rather easy appearance. Large handlers offered the lower grades at 16@17c. per lb. In outside channels scattered lots could have been picked up at 15½c. per lb.

Glycerine—There were sellers of the chemically pure in the West at 15⅝c. per lb., in drums, carload lots. The market in New York was unsettled at 16½@17c. per lb., in drums, the price varying according to the seller. Recent trading in dynamite was put through at 15c. per lb., in drums, carload lots, about 25 carloads being involved. At the close the market for dynamite glycerine was more or less nominal as regards prices, most holders asking from 15¼@15½c. per lb., the inside figure obtaining in the Middle West. Crude soap lye, basis 80 per cent, settled at 9⅝c. bid and 10c. asked, loose, carload lots, f.o.b. shipping point.

Naval Stores—The market went off slightly on lack of buying interest. Receipts at Southern points were liberal, but no real selling pressure developed. Spirits of turpentine closed at $1.04 per gal., but on a firm bid it was intimated that this price might be shaded. Rosins ruled steady in sympathy with the market in the South, but not much new business was put through. The "B" grade held at $5.80 per bbl.

Rubber—Reports on the state of the rubber trade were not so optimistic. Continental operators in crude showed no interest in the market, and with America less active on the buying side prices eased off. First latex and ribbed smoked sheets on spot were offered at 27c. per lb., with October-November-December nominal at 28c. per lb.

Shellac—The market was unsettled on lower cables from Calcutta. Demand was quiet and T. N. was offered ex-store at 58c. per lb. On ex-dock transactions as low as 55½c. was named during the week. Orange superfine closed at 62c. asked. Bleached, bone dry, held around 68@70c. per lb., as to position and seller.

White Lead—Withdrawals against existing contracts were liberal enough, but new business did not come forward in volume. Corroders offered lead pigments on the guarantee against decline basis, yet this did not stimulate business. The metal was easier in the West, but nominally unchanged in New York at 7¼c. per lb. Standard dry white lead held at 9⅞c. per lb., in casks, carload lot basis.

Zinc Oxide—Consumption of zinc oxide is likely to meet with a setback, as several of the larger tire manufacturers have announced that production will be curtailed over the summer months. However, this did not bring out an easier situation in zinc oxide and producers continued to quote on the former basis of 8c. per lb., on the American process, lead free. French process, red seal, settled at 9⅝c. per lb., round-lot basis. East St. Louis reported weakness in the metal, spelter closing around 5.95c. per lb.

London Tallow Auction

At the regular weekly tallow auction, held in London, June 20, 1,441 casks were offered and 1,142 casks sold. Prices realized were unchanged to 1 shilling higher.

Imports at the Port of New York

June 15 to June 21

ACIDS — Tartaric — 100 csk., Palermo, Order; 150 bbl., Genoa, L'Appula Soc Amon.; 2 bbl., San Juan, Powers-Weightman & Rosengarten.

ALCOHOL—85 bbl. denatured, Arecibo, C. Esteva; 25 bbl. do., Arecibo, M. Feigel & Bros.

ALIZARINE—2 csk., Hamburg, Kuttroff, Pickhardt & Co.

ARSENIC—100 cs., Kobe, Irving Bank-Col. Trust Co., 15 cs., Kobe, S. W. Bridges & Co.; 50 cs., Kobe, Frazer & Co., 200 cs., Kobe, Order.

BLANC FIXE—40 csk., Hamburg, P. Uhlich & Co.

BRONZE POWDER—92 cs., Bremen, Baer Bros; 23 cs., Bremen, Hensel, Bruckmann & Lorbacher; 24 cs., Bremen, Uhlfelder & Co.; 8 cs., Bremen, Order.

CAMPHOR—350 cs., Hamburg, A. Ochse & Co.

CASEIN—297 bg., Bombay, Order, 333 bg., London, Bank of America, 250 bg., Hamburg, Jungmann & Co.; 134 bg., Hamburg, A. Klipstein & Co.

CHEMICALS—98 pkg., Bremen, Pfaltz & Bauer; 300 bg., Glasgow, Brown Bros. & Co.; 17 cs., Hamburg, Morgenstern & Co; 50 csk., Rotterdam, Stanley Doggett, 40 csk., London, A. Klipstein & Co., 38 pkg., Hamburg, Hummel & Robinson; 372 pkg., Hamburg, Roessler & Hasslacher Chem. Co.; 7 csk., Hamburg, Bank of the Manhattan Co.; 270 csk., Hamburg, Jungmann Co.; 19 csk, Hamburg, Order; 21 bbl., Hamburg, A. Murphy & Co.

CHALK—506 tons, London, Baring Bros. & Co.; 2,000 bg., Antwerp, Cooper & Cooper, Inc.; 200 bg., Antwerp, Irving Bank-Col Trust Co.; 1,500 bg., Antwerp, Bankers Trust Co.; 115 bg., London, Order.

CHROME ORE—2,000 tons; Beira, E. J. Lavino & Co.

CINCHONINE—21 cs., Rotterdam, R. W. Greeff & Co.

CREAM TARTAR—50 csk, Hamburg, Order.

COLORS—20 cs., Bremen, Sigmund Ullman Co; 50 csk. earth, Bremen, L. H. Butcher & Co.; 5 csk. aniline, Havre, Sandoz Chemical Works; 7 csk. do, Havre, Irving Bank-Col. Trust Co.; 27 pkg. do., Havre, Geigy Co.; 6 csk. do., Havre, Carbic Color & Chemical Co.; 20 bbl., earth, Leghorn, Reichard-Coulston, Inc.; 68 bbl. do, Leghorn, Order; 16 csk. earth, Marseilles, C. F. Gledhill; 3 csk, Bremen, O. Hommel Co.; 21 csk. earth, Hamburg, P. Uhlich & Co.; 25 csk. earth, Hamburg, J. L. Smith & Co., 34 csk. aniline, Hamburg, Kuttroff, Pickhardt & Co.; 4 csk do. Hamburg, Order, 15 csk., Hamburg, Gresselli Chem. Co.; 3 csk. do., Hamburg, Carbic Color & Chem. Co.; 4 csk do. Hamburg, G. A. Kuhl; 7 csk aniline, Rotterdam, H. A. Metz & Co.; 14 bbl., Hamburg, Fezandie & Sperrle

COPPER OXIDE—50 dr., Hamburg, Am. Metal Co.

COPRA—327,000 lb., Belize, Franklin Baker Co.; 169 bg., Morant Bay, Franklin Baker Co; 303 bg., Port Antonio, Fandrell Import Co.; 37 bg., San Juan, Order.

DYESTUFFS—33 csk., Naples, Irving Bank-Col Trust Co.; 16 csk., Naples, Am. Exchange Nat'l Bank; 10 csk., Naples, Order; 5 csk., Naples, Ladenburg, Thalmann & Co.; 2 csk., Naples, Ackermann Color Co.; 7 cs., Havre, Selchow & Righter; 4 cs., Havre, R. H. Meehan & Co.; 2 cs., Havre, B. F. Drakenfeld & Co.; 4 csk., Havre, Sandoz Chem. Wks.

FULLERS EARTH—1250 bg, London, L. A. Salomon & Bro.

FUSEL OIL—21 dr., Rotterdam, G. W. Sheldon & Co.; 3 dr. Rotterdam, Order.

GLAUBER SALT—335 csk., Hamburg, Innis, Speiden & Co.; 200 bg., Hamburg, A. J. Marcus; 251 bbl., Hamburg, E. Suter & Co.

GUMS—324 bg. copal, Antwerp, Equitable Trust Co.; 200 bg. do., Antwerp, Brown Bros. & Co; 124 cs. kauri, Auckland, Baring Bros. & Co.; 48 pkg. do., Auckland, Brown Bros. & Co.; 47 cs. do., Auckland, Equitable Trust Co.; 332 bg. do., Auckland, Am. Foreign Banking Corp.; 95 cs. do., Auckland, Guaranty Trust Co.; 122 cs. and 359 sk., Auckland, Chemical Nat'l Bank; 1204 pkg. kauri, Auckland, Order; 209 bg. yacca, Port Adelaide, Baring Bros. & Co.; 400 bg. do., Port Adelaide, W. Schall & Co.; 546 bg. ghaty, 527 bg. karaya, 259 pkg. tragacanth, 56 bg. asafoetida, 225 bg. olibanum, Bombay, Order, 290 bg. copal, Antwerp, Order; 1,400 cs. damar, Batavia, National City Bank; 200 cs. do., Batavia, Innes & Co., 100 cs. do Batavia, W. Schall & Co.; 200 cs do., Batavia, Bank of Cent. & South Am., 2,250 cs. do., Batavia Order; 487 bg. copal, Antwerp, W. Schall & Co.; 620 pkg do Antwerp, Central Union Trust Co.; 205 bg do. Antwerp, Chemical National Bank, 105 bg. do Antwerp Brown Bros & Co.; 26 cs kauri, London, Order; 1,240 bg. yacca, Adelaide, International Banking Corp; 141 bg. do., Adelaide, Order.

IRON OXIDE—10 csk., Marseilles, C. F. Gledhill; 200 bbl. Malaga, Scott L. Libby Corp, 170 bbl., Malaga C. K. Williams & Co, 100 bbl. Malaga, E. M. & F. Waldo; 82 bbl Malaga, J. M. Rabass; 80 bbl Malaga, Nat'l City Bank; 110 bbl., Malaga, Reichard Coulston, Inc.

LITHOPONE—300 cks., Antwerp, Benja. Moore & Co.

LOGWOOD EXTRACT—141 bbl, Cape Haitian, Logwood Mfg. Corp.

MENTHOL—25 cs. Kobe, National City Bank, 25 cs., Kobe, Stanley, Jordan & Co

MAGNESITE 104 bbl., Rotterdam, Speiden-Whitfield Co

MAGNESIUM—225 cs. citrate, Naples, Order, 500 cs do., Naples, East River Nat'l Bank., 3 bg. chloride, Hamburg, Innis, Speiden & Co., 150 dr. chloride, Hamburg, Order

MYROBALANS—4,000 pkt., Calcutta, Standard Bank of South Africa, 10,972 bg., Bombay, Order, 14,426 pkt., Calcutta, Order.

OILS—Olive Oil Foots—100 bbl, Palermo Banca Comm. Italo; 100 bbl. Palermo, Order, 100 bbl, Patras, G. Barnalas. **Palm**—500 csk, Hamburg, African & Eastern Trading Corp. **Seal**—140 tons in bulk, St Johns, Cook & Sevan Co, 154 tons in bulk, St. Johns, Bowring & Co.

OIL SEEDS—Castor—10928 bg., Coconada, Volkart Bros.; 1426 bg., Bombay, Order; 89 bg., Port de Paix, Huttlinger & Struller. **Linseed**—26,429 bg. and 3,724 409 kilos, in bulk Rosario, Spencer Kellogg & Sons; 102,342 bg., Rosario, Spencer Kellogg & Sons; 36,324 bg., Rosario, L. Dreyfus & Co.; 32,537 bg., San Nicolas, L. Dreyfus & Co, 22,400 bg, Buenos Aires, Order, 17,929 bg., Bahia Blanca, L. Dreyfus & Co.; 35,392 bg., Bahia Blanca, Order; 37,316 bg., Rosario, Order; 18,813 bg., San Nicolas, Order.

POTASSIUM SALTS—1500 bg. muriate and 1500 bg. sulphate, Bremerhaven, Potash Imp. Corp. of Am.; 7,000 bg. muriate, Soc Comm. des Potasses d'Alsace; 182 dr. permanganate, Hamburg, Brown Bros. & Co; 3,000 bbl. chlorate, Hamburg, Order, 42 pkg permanganate, Hamburg, Order; 31 bbl. hydrate, Hamburg, A. J. Marcus, Inc.; 1,000 bbl. chlorate, Hamburg, Irving Bank-Col. Trust Co.; 18 csk. carbonate, Hamburg, Peters, White & Co.; 174 dr caustic, Hamburg, E. Suter & Co.; 225 csk nitrate, Hamburg, Kuttroff, Pickhardt & Co.

PYRIDINE—1 csk., Hamburg, Order.

QUEBRACHO—10,466 bg., Buenos Aires, Tannin Corp.; 8,524 bg., Buenos Aires, Beckman & Winthrop; 8,210 bg., Buenos Aires, Fourth Atlantic National Bank; 1,000 tons, Buenos Aires, Tannin Corp.

SHELLAC—750 bg., Calcutta, Order; 100 bg., and 20 cs., Calcutta, Brown Bros. & Co.; 40 cs. garnet, Calcutta, First Nat'l Bank of Boston; 300 bg., Calcutta, Chase National Bank; 100 bg., Calcutta, N. Y. Trust Co.; 100 bg., Calcutta, Mech. & Metals National Bank; 100 bg., Calcutta, Iwai & Co.; 600 bg. refuse, Calcutta, Bank of the Manhattan Co.; 100 bg., Calcutta, British Bank of South Am.; 100 chests, Calcutta, Philadelphia Nat'l Bank; 1,356 pkg., Calcutta, Order; 50 bg. garnet, Hamburg, Kasebier-Chatfield Shellac Co.; 10 cs., Rotterdam, A. Murphy & Co.

SODIUM SALTS—100 cs. chlorate, Genoa, A. H. Pickering & Co.; 144 cs. do., Genoa, Order; 19,562 bg. nitrate, Iquique, W. R. Grace & Co.; 2,755 bg. nitrate, Antofogasta, W. R. Grace & Co.; 33 csk. prussiate, Rotterdam, C. F. Smillie & Co.; 200 cs. cyanide, Havre, National City Bank; 216 cs. sulphite, Hamburg, C. S. Grant & Co.; 75 csk. nitrate, Hamburg, E. Suter & Co.

STRONTIUM NITRATE—44 bbl., Hamburg, Unexcelled Mfg. Co.

STARCH—1,250 bg., potato, Rotterdam, Stein, Hall & Co.; 250 bg. do., Rotterdam, J. Wertheimer & Sons; 200 bg. do., Rotterdam, Chic Starch Co.

SUMAC—350 bg. Palermo, American Express Co.; 550 bg., Palermo, Order.

TALC—3,500 bg., Genoa, Italian Discount & Trust Co.; 250 bg., Genoa, Bankers Trust Co

TARTAR — 16 csk., Messina, Tartar Chem. Works.

TARTRATE OF LIME—237 bg, Valencia, C. Pfizer & Co.

WAXES—875 bg. montan, Bremen, W. Schall & Co.; 97 bg. bees, Valparaiso, Duncan, Fox & Co.; 40 cs. bees, Havre, L. A. Salomon & Bros.; 377 bg. carnauba, Cara, Int'l Acceptance Bank, 223 bg. do., Parnahyba, Lazard Freres; 979 bg. do., Parnahyba, National City Bank; 19 pkg. bees, Talcahuano, W. R. Grace & Co.; 72 bg. bees, Valparaiso, Banco Aleman Trans-Atlantic; 56 bg. do., Valparaiso, W. R. Grace & Co.; 50 bbl. beeswax, Rotterdam, Knauth, Nachod & Kuhne; 1,920 bg. paraffine, London, Order; 32 bg. bees, London, Order.

WOOL GREASE—75 bbl, Bremen, Hummel & Robinson Corp

ZINC OXIDE—50 bbl., Antwerp, Reichard-Coulston, Inc.

ZINC WHITE—20 csk., Southampton, Houbigart, Inc.

Current Prices in the New York Market

For Chemicals, Oils and Allied Products

THESE prices are for the spot market in New York City, but a special effort has been made to report American manufacturers' quotations whenever available. In many cases these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported stocks are reported when they are of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetone, drums	lb.	$0.25 - .25½
Acid, acetic, 28%, bbl.	100 lb.	3.38 - 3.50
Acetic, 56%, bbl	100 lb.	6.75 - 7.00
Glacial, 99½%, bbl.	100 lb.	12.00 - 12.50
Acetic anhydride, 85%, dr.	lb.	.58 -
Boric, bbl	lb.	.10½ -
Citric, kegs	lb.	.49 - .52
Formic, 85%	lb.	.14 - .16
Gallic, tech.	lb.	.45 - .50
Hydrofluoric, 52%, carboys	lb.	.11 - .12
Lactic, 44% tech., light, bbl.	lb.	.11½ - .12
22% tech., light, bbl.	lb.	.05½ - .06
Muriatic, 18° tanks	100 lb.	.90 - 1.00
Muriatic, 20°, tanks,	100 lb.	1.00 - 1.10
Nitric, 36°, carboys	lb.	.04½ - .05
Nitric, 42°, carboys	lb.	.06 - .06½
Oleum, 20%, tanks	ton	18.50 - 19.00
Oxalic, crystals, bbl.	lb.	.13 - .13½
Phosphoric, 50% carboys	lb.	.07½ - .08½
Pyrogallic, resublimed	lb.	1.50 - 1.60
Sulphuric, 60°, tanks	ton	9.50 - 11.00
Sulphuric, 60°, drums	ton	13.00 - 14.00
Sulphuric, 66°, tanks	ton	16.00 - 16.50
Sulphuric, 66° drums	ton	20.00 - 21.00
Tannic, U.S.P., bbl.	lb.	.65 - .70
Tannic, tech., bbl.	lb.	.45 - .50
Tartaric, imp., powd., bbl.	lb.	.35½ - .36
Tartaric, domestic, bbl.	lb.	.37½ -
Tungstic, per lb.	lb.	1.10 - 1.20
Alcohol, butyl, drums, f.o.b. works	lb.	.26 - .28
Alcohol ethyl (Cologne spirit), bbl	gal.	4.75 - 4.95
Ethyl, 190 p'f. U.S.P., bbl.	gal.	4.70 -
Alcohol, methyl (see Methanol)		
Alcohol, denatured, 190 proof		
No. 1, special bbl.	gal.	.41 -
No. 1, 190 proof, special, dr.	gal.	.35 -
No. 1, 188 proof, bbl	gal.	.42 -
No. 1, 188 proof, dr	gal.	.36 -
No. 5, 188 proof, bbl	gal.	.40 -
No. 5, 188 proof, dr	gal.	.34 -
Alum, ammonia, lump, bbl	lb.	.03½ - .03¾
Potash, lump, bbl	lb.	.02¾ - .03¼
Chrome, lump, potash, bbl.	lb.	.05½ - .05¾
Aluminum sulphate, com., bags	100 lb.	1.50 - 1.65
Iron free bags	lb.	.02½ - .02¾
Aqua ammonia, 26°, drums	lb.	.06½ - .07
Ammonia, anhydrous, cyl.	lb.	.30 - .30½
Ammonium carbonate, powd. casks, imported	lb.	.09½ - .10
Ammonium carbonate, powd. domestic, bbl.	lb.	.13 - .14
Ammonium nitrate, tech., casks	lb.	.10 - .11
Amyl acetate tech., drums	gal.	3.75 - 4.25
Arsenic, white, powd., bbl	lb.	.13½ - .14
Arsenic, red, powd., kegs	lb.	.15½ - .16
Barium carbonate, bbl.	ton	70.00 - 75.00
Barium chloride, bbl.	ton	80.00 - 83.00
Barium dioxide, drums	lb.	.18 - .18½
Barium nitrate, casks	lb.	.08 - .08½
Blanc fixe, dry, bbl.	lb.	.04 - .04½
Bleaching powder, f.o.b. wks., drums	100 lb.	1.90 -
Spot N. Y. drums	100 lb.	2.40 -
Borax, bbl.	lb.	.05½ - .05¾
Bromine, cases	lb.	.28 - .30
Calcium acetate, bags	100 lb.	4.00 - 4.05
Calcium arsenate, dr	lb.	.14 - .16
Calcium carbide, drums	lb.	.05½ - .05¾
Calcium chloride, fused, drums	ton	22.00 - 23.00
Gran. drums	ton	28.00 - 30.00
Calcium phosphate, mono, bbl.	lb.	.06½ - .07
Camphor, cases	lb.	.86 - .88
Carbon bisulphide, drums	lb.	.07 - .07½
Carbon tetrachloride, drums	lb.	.09½ - .10
Chalk, precip.—domestic, light, bbl.	lb.	.04½ - .04¾
Domestic, heavy, bbl.	lb.	.03½ - .03¾
Imported, light, bbl.	lb.	.04½ - .05
Chlorine, liquid, tanks, wks.	lb.	.05½ - .05¾
Cylinders, 100 lb., wks	lb.	.06 - .06½
Cylinders, 100 lb., spot	lb.	.09 -
Chloroform, tech., drums	lb.	.35 - .38
Cobalt oxide, bbl.	lb.	2.10 - 2.25
Copperas, bulk, f.o.b. wks.	ton	20.00 - 21.00
Copper carbonate, bbl.	lb.	.19 - .20
Copper cyanide, drums	lb.	.47 - .50
Coppersulphate, dom., bbl.,	100 lb.	5.50 - 5.75
Imp. bbl	100 lb.	5.00 - 5.25
Cream of tartar, bbl.	lb.	.25½ - .26½
Epsom salt, dom., tech., bbl.	100 lb.	1.90 - 2.15
Epsom salt, imp., tech., bags	100 lb.	.90 - 1.00
Epsom salt, U.S.P., dom., bbl.	100 lb.	2.50 - 2.60
Ether, U.S.P., resale, dr.	lb.	.13 - .15
Ethyl acetate, 85%, drums	gal.	.80 - .81
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	.95 - 1.00

Formaldehyde, 40%, bbl.	lb.	$0.14½ - $0.15
Fullers earth—imp., powd., net	ton	30.00 - 32.00
Fusel oil, ref., drums	gal.	-
Fusel oil, crude, drums	gal.	3.75 - 4.00
Glaubers salt, wks., bags	100 lb.	1.20 - 1.40
Glaubers salt, imp., bags	100 lb.	.90 - .95
Glycerine, c.p., drums extra	lb.	.16½ - .17
Glycerine, dynamite, drums	lb.	.15½ - .15¾
Glycerine, crude 80%, loose	lb.	.10 - .10½
Iodine, resublimed	lb.	4.55 - 4.65
Iron oxide, red, casks	lb.	.12 - .18
Lead:		
White, basic carbonate, dry, casks	lb.	.09¾ - .10
White, basic sulphate, casks	lb.	.09½ -
White, in oil, kegs	lb.	.12½ - .14
Red, dry, casks	lb.	.11½ - .12
Red, in oil, kegs	lb.	.13½ - .15
Lead acetate, white crys., bbl.	lb.	.14 - .14½
Brown, broken, casks	lb.	.13 - .13½
Lead arsenate, powd., bbl.	lb.	.23 - .24
Lime-Hydrated, bbl.	per ton	16.80 - 17.00
Lime, Lump, bbl.	280 lb.	3.63 - 3.65
Litharge, comm., casks	lb.	.10½ - .11
Lithophone, bags	lb.	.07 - .07½
in bbl.	lb.	.07½ - .07¾
Magnesium carb., tech., bags	lb.	.08½ - .08¾
Methanol, 95%, bbl	gal.	1.18 - 1.20
Methanol, 97%, bbl.	gal.	1.20 - 1.22
Nickel salt, double, bbl.	lb.	.10½ -
Nickel salts, single, bbl.	lb.	.11½ -
Phosgene		.60 - .75
Phosphorus, red, cases	lb.	
Phosphorus, yellow, cases	lb.	.35 - .40
Potassium bichromate, casks	lb.	.11 - .11½
Potassium bromide, gran., bbl	lb.	.19 - .20
Potassium carbonate, 80-85%, calcined, casks	lb.	.06½ - .06¾
Potassium chlorate, powd.	lb.	.07½ - .08
Potassium cyanide, drums	lb.	.47 - .52
Potassium, first sorts, cask	lb.	.07½ - .08
Potassium hydroxide (caustic potash) drums	lb.	.07½ - .09
Potassium iodide, cases	lb.	3.65 - 3.75
Potassium nitrate, bbl.	lb.	.06½ - .07½
Potassium permanganate, drums	lb.	.17 - .18
Potassium prussiate, red, casks	lb.	.65 - .67
Potassium prussiate, yellow, casks	lb.	.31 - .33
Salammoniac, white, gran., casks, imported	lb.	.06½ - .06¾
Salammoniac, white, gran., bbl., domestic	lb.	.07½ - .07
Gray, gran., casks	lb.	.08 - .09
Salsoda, bbl.	100 lb.	1.20 - 1.40
Salt cake (bulk)	ton	26.00 - 28.00
Soda ash, light, 58% flat, bags, contract	100 lb.	1.45 - 1.50
Soda ash, light, 58%, flat, bags, resale	100 lb.	1.70 - 1.75
Soda ash, dense, bags, contract, basis 58%	100 lb.	1.51 -
Soda ash, dense, in bags, resale	100 lb.	1.85 - 1.90
Soda, caustic, 76%, solid, drums	100 lb.	3.16½ -
Soda, caustic, ground and flake, contracts	100 lb.	3.60 - 3.85
Soda, caustic, ground and flake, resale	100 lb.	3.72½ -
Sodium acetate, works, bags	lb.	.05½ - .06½
Sodium bicarbonate, bbl.	100 lb.	2.00 - 2.50
Sodium bichromate, casks	lb.	.08½ - .09
Sodium bisulphate (niter cake)	ton	6.00 - 7.00
Sodium bisulphite, powd., U.S.P., bbl.	lb.	.04½ - .04¾
Sodium chlorate, kegs	lb.	.06½ - .07
Sodium chloride	long ton	12.00 - 13.00
Sodium cyanide, cases	lb.	.20 - .23
Sodium fluoride, bbl.	lb.	$0.08½ - $0.10½
Sodium hyposulphite, bbl.	lb.	.02½ - .03
Sodium nitrite, casks	lb.	.07½ - .07¾
Sodium peroxide, powd., cases	lb.	.28 - .30
Sodium phosphate, dibasic, bbl.	lb.	.03½ - .04
Sodium prussiate, yel. drums	lb.	.14½ - .16
Sodium salicylic, drums	lb.	.47 - .52
Sodium silicate (40°, drums)	100 lb.	.75 - 1.15
Sodium silicate (60°, drums)	100 lb.	1.75 - 2.00
Sodium sulphide, fused, 60-62% drums	lb.	.04½ - .04¾
Sodium sulphite, crys., bbl.	lb.	.03½ - .03¾
Strontium nitrate, powd., bbl.	lb.	.12½ - .13
Sulphur chloride, yel drums	lb.	.04½ - .05
Sulphur, crude	ton	18.00 - 20.00
At mine, bulk	ton	16.00 - 18.00
Sulphur, flour, bag	100 lb.	2.25 - 2.35
Sulphur, roll, bag	100 lb.	2.00 - 2.10
Sulphur dioxide, liquid, cyl.	lb.	.08 - .08½
Talc—imported, bags	ton	30.00 - 40.00
Talc—domestic powd., bags	ton	18.00 - 25.00
Tin bichloride, bbl.	lb.	.12½ - .13
Tin oxide, bbl.	lb.	.48 -
Tin crystals, bbl.	lb.	.34½ - .35
Zinc carbonate, bags	lb.	.14 - .14½
Zinc chloride, gran, bbl.	lb.	.06½ - .06¾
Zinc cyanide, drums	lb.	.37 - .38
Zinc oxide, lead free, bbl	lb.	.08 - .08½
5% lead sulphate, bags	lb.	.07½ - ......
10 to 35 % lead sulphate, bags	lb.	.07 - ......
French, red seal, bags	lb.	.09½ - ......
French, green seal, bags	lb.	.10½ - ......
French, white seal, bbl	lb.	.12 - ......
Zinc sulphate, bbl.	100 lb.	2.50 - 3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl.	lb.	$0.62 - $0.75
Alpha-naphthol, ref., bbl.	lb.	.70 - .80
Alpha-naphthylamine, bbl.	lb.	.35 - .37
Aniline oil, drums	lb.	.16 - .16
Aniline salts, bbl	lb.	.23 - .24
Anthracene, 80%, drums	lb.	.75 - 1.00
Anthracene, 80%, imp., drums, duty paid	lb.	.70 - .75
Anthraquinone, 25% paste, drums	lb.	.70 - .75
Benzaldehyde U.S.P., carboys	lb.	1.40 - 1.45
tech, drums	lb.	.75 - .80
Benzene, pure, water-white, tanks and drums	gal.	.27 - .32
Benzene, 90%, tanks & drums	gal.	.25 - .30
Benzene, 90%, drums, resale	gal.	.28 - .32
Benzidine base, bbl.	lb.	.80 - .85
Benzidine sulphate, bbl.	lb.	.70 - .75
Benzoic acid, U.S.P., kegs	lb.	.75 - .80
Benzoate of soda, U.S.P., bbl.	lb.	.57 - .65
Benzyl chloride, 95-97%, ref., drums	lb.	.45 -
Benzyl chloride, tech., drums	lb.	.30 - .35
Beta-naphthol, tech., bbl.	lb.	.21½ - .22
Beta-naphthylamine, tech.	lb.	.80 - .90
Cresol, U.S.P., drums	lb.	.25 - .29
Ortho-cresol, drums	lb.	.28 - .3[illegible]
Cresylic acid, 97%, resale, drums	gal.	1.15 - 1.20
95-97%, drums, resale	gal.	1.05 - 1.10
Dichlorbenzene, drums	lb.	.07 - .09
Diethylaniline, drums	lb.	.50 - .60
Dimethylaniline, drums	lb.	.41 - .4[illegible]
Dinitrobenzene, bbl.	lb.	.19 - .20
Dinitroclorbenzene bbl.	lb.	.22 - .2[illegible]
Dinitronaphthalen, bbl.	lb.	.30 - .3[illegible]
Dinitrophenol, bbl.	lb.	.35 - .40
Dinitrotoluene, bbl.	lb.	.20 - .2[illegible]
Dip oil, 25%, drums	gal.	.25 - .30
Diphenylamine, bbl.	lb.	.50 - .5[illegible]
H-acid, bbl.	lb.	.75 - .80
Meta-phenylenediamine, bbl.	lb.	1.00 - 1.0[illegible]
Michlers ketone, bbl.	lb.	3.00 - 3.50
Monochlorbenzene, drums	lb.	.08 - .1[illegible]
Monoethylaniline, drums	lb.	.95 - 1.1[illegible]
Naphthalene, flake, bbl.	lb.	.07½ - .0[illegible]
Naphthalene, balls, bbl.	lb.	.08½ - .0[illegible]
Naphthionate of soda, bbl.	lb.	.58 - .6[illegible]
Naphthionic acid, crude, bbl.	lb.	.55 - .60
Nitrobenzene, drums	lb.	.10 - .1[illegible]
Nitro-naphthalene, bbl.	lb.	.30 - .3[illegible]
Nitro-toluene, drums	lb.	.13½ - .1[illegible]
N-W acid, bbl.	lb.	1.25 - 1.3[illegible]
Ortho-amidophenol, kegs	lb.	2.30 - 2.3[illegible]
Ortho-dichlorbenzene, drums	lb.	.17 - .2[illegible]
Ortho-nitrophenol, bbl.	lb.	.90 - .9[illegible]
Ortho-nitrotoluene, drums	lb.	.10 - .1[illegible]
Ortho-toluidine, bbl.	lb.	.13 - .1[illegible]
Para-amidophenol, base, kegs	lb.	1.30 - 1.3[illegible]
Para-amidophenol, HCl, kegs	lb.	1.25 - 1.3[illegible]
Para-dichlorbenzene, bbl.	lb.	.17 - .2[illegible]
Paranitroaniline, bbl.	lb.	.70 - .7[illegible]
Para-nitrotoluene, bbl.	lb.	.60 - .6[illegible]
Para-phenylenediamine, bbl.	lb.	1.45 - 1.5[illegible]
Para-toluidine, bbl	lb.	.90 - .9[illegible]
Phthalic anhydride, bbl.	lb.	.35 - .3[illegible]
Phenol, U.S.P., resale, dr.	lb.	.42 - .4[illegible]
Picric acid, bbl.	lb.	.20 - .2[illegible]
Pyridine, dom., drums	gal.	nominal

Pyridine, imp., drums	gal	$4 00 - $4 25
Resorcinol, tech., kegs	lb.	1.50 - 1 60
Resorcinol, pure, kegs	lb.	2 25 -
R-salt, bbl	lb.	.55 - .60
Salicylic acid, tech., bbls	lb.	.37 - .42
Salicylic acid, U.S.P., bbl	lb.	.40 - .45
Solvent naphtha, water-white, tanks	gal.	.27 -
Crude, tanks	gal.	.24 -
Sulphanilic acid, crude, bbl	lb.	.18 - .20
Thiocarbanilide, kegs	lb.	.35 - .38
Toluidine, kegs	lb.	1.20 - 1.30
Toluidine, mixed, kegs	lb.	.30 - .35
Toluene, tank cars	gal.	.30 - .35
Toluene, drums	gal.	.34 - .36
Xylidines drums	lb.	.49 - .50
Xylene, pure, drums	gal.	.75 - 1 00
Xylene, com., drums	gal	.37 -
Xylene, com., tanks	gal.	.32 - ......

Naval Stores

Rosin B-D, bbl	280 lb.	$5 80 -
Rosin E-I, bbl	280 lb	5 90 -
Rosin K-N, bbl	280 lb	6 10 -
Rosin W.G.-W.W., bbl	280 lb	6 25 - 7 25
Wood rosin, bbl	280 lb	5 90 - 6 00
Turpentine, spirits of, bbl	gal	1 03 -
Wood, steam dist., bbl	gal	96 -
Wood, dest dist., bbl	gal.	65 -
Pine tar pitch, bbl	200 lb	- 6 00
Tar, kiln burned, bbl	500 lb	- 13 00
Retort tar, bbl	500 lb	- 12 00
Rosin oil, first run, bbl	gal	
Rosin oil, second run, bbl	gal	48 - ...
Rosin oil, third run, bbl	gal	52 -
Pine oil, steam dist	gal.	70 - ..
Pine oil, pure, dest dist	gal	65 - ..
Pine tar oil, ref	gal.	48 - ..
Pine tar oil, crude, tanks f.o.b Jacksonville, Fla.	gal.	32 - .32½
Pine tar oil, double ref., bbl	gal	- 75
Pine tar, ref., thin, bbl	gal	- .25
Pinewood creosote, ref., bbl	gal	- 52

Animal Oils and Fats

Degras, bbl	lb	$0 03½ - $0 04
Grease, yellow, bbl	lb	06½
Lard oil, Extra No. 1, bbl	gal	90
Neatsfoot oil 20 deg bbl	gal	1 30 -
No. 1, bbl	gal	92 - 94
Oleo Stearine		08½
Red oil, distilled, d p bbl	lb	.10 -
Saponified, bbl	lb	10
Tallow, extra, loose	lb	07½
Tallow oil, acidless, bbl	gal	94 - 96

Vegetable Oils

Castor oil, No 3, bbl	lb	$0 14 -
Castor oil, No 1, bbl	lb	14½ -
Chinawood oil, bbl	lb.	.26 -
Coconut oil, Ceylon, bbl	lb	09½ - 09½
Ceylon, tanks, N Y	lb	08½ - 08½
Coconut oil, Cochin, bbl	lb	09½ - 10
Corn oil, crude, bbl	lb.	12½
Crude, tanks, (f o b mill)	lb.	09½ - 09½
Cottonseed oil, crude (f.o.b. mill), tanks	lb.	.09½
Summer yellow, bbl	lb.	12½ - 12½
Winter yellow, bbl	lb.	.13 -
Linseed oil, raw, car lots, bbl.	gal	1 08 -
Raw, tank cars (dom)	gal	1 03 -
Boiled, cars, bbl (dom)	gal	1 10 -
Olive oil, denatured, bbl	gal.	1 05 - 1 10
Sulphur, (foots) bbl	lb.	.07½ - 07½
Palm, Lagos, casks	lb.	.07 -
Niger casks	lb.	06½
Palm kernel, bbl	lb.	.08½ - .08½
Peanut oil, crude, tanks (mill)	lb	.12½ - 13
Peanut oil, refined, bbl	lb.	.16½ -
Perilla, bbl	lb	15½ - 15½
Rapeseed oil, refined, bbl	gal.	.78 -
Rapeseed oil, blown, bbl	gal.	.85 -
Sesame, bbl	lb	11½ - 12
Soya bean (Manchurian), bbl.	lb.	.12½
Tank, f o b Pacific coast	lb.	.09½ - 09½
Tank, (f o b. N.Y.)	lb.	.09½ - ..

Fish Oils

Cod, Newfoundland, bbl	gal.	$0 70 - $0 72
Menhaden, light pressed, bbl.	gal.	.76 -
White bleached, bbl.	gal.	.78 -
Blown, bbl.	gal.	.82 - ...
Crude, tanks (f o b factory)	gal.	.50 -
Whale No. 1 crude, tanks, coast	lb.	-
Winter, natural, bbl	gal.	76 - 78
Winter, bleached, bbl	gal	79 - .80

Oil Cake and Meal

Coconut cake, bags	ton	$26 00 - $28.00
Copra, sun dried, bags, (c i f)	lb.	05 -
Sun dried Pacific coast.	lb	04½ -
Cottonseed meal, f o b. mills	ton	38 00 -
Linseed cake, bags	ton	37 00 -
Linseed meal, bags	ton	39 00 -

Dye & Tanning Materials

Albumen, blood, bbl.	lb.	$0 45 - $0 50
Albumen, egg, tech, kegs	lb.	.95 - .97
Cochineal, bags	lb.	.33 - .35
Cutch, Borneo, bales	lb.	.04½ - .04½
Cutch, Rangoon, bales	lb.	.13 - .13½
Dextrine, corn, bags	100 lb.	3 84 - 4.25
Dextrine, gum, bags	100 lb.	4.14 - 4.34
Divi-divi, bags	ton	38.00 - 39.00
Fustic, sticks	ton	30.00 - 35.00
Fustic, chips, bags	lb.	.04 - .05
Logwood, sticks	ton	26.00 - 30.00
Logwood, chips bags	lb.	.02½ - .03½
Sumac, leaves, Sicily, bags	ton	70.00 - 72.00
Sumac, ground, bags	ton	$65 00 - $67 00
Sumac, domestic, bags	ton	40 00 - 42 00
Starch, corn, bags	100 lb	3.22 - 3.49
Tapioca flour, bags	lb.	06½ - .07

Extracts

Archil, conc., bbl	lb.	$0 17 - $0 18
Chestnut, 25% tannin, tanks	lb	02 - .03½
Divi-divi, 25% tannin, bbl	lb	04 - .05
Fustic, crystals, bbl	lb	20 - .22
Fustic, liquid, 42°, bbl	lb.	08 - .09
Gambier, liq., 25% tannin, bbl.	lb.	08 - .09
Hematine crys., bbl	lb.	.14 - .18
Hemlock, 25% tannin, bbl	lb.	03½ - .04½
Hypernic, solid, drums	lb.	24 - .26
Hypernic, liquid, 51°, bbl	lb.	09½ - .10½
Logwood, crys., bbl	lb.	17 - .18
Logwood, liq., 51°, bbl	lb.	.08½ - .09
Quebracho, solid, 65% tannin, bbl.	lb.	.04½ - .05
Sumac, dom., 51°, bbl	lb	.06½ - .07

Dry Colors

Blacks-Carbongas, bags, f o b works, spot	lb	$0 20 - $0.24
Lampblack, bbl	lb	12 - .40
Mineral, bulk	ton	35 00 - 45 00
Blues-Bronze, bbl	lb	.55 - 60
Prussian, bbl	lb.	55 - 60
Ultramarine, bbl	lb.	.08 - 35
Browns, Sienna, Ital., bbl	lb	06 - 14
Sienna, Domestic, bbl	lb	03½ - 04
Umber, Turkey, bbl	lb	.04 - 04½
Greens-Chrome, C P Light, bbl	lb.	32 - .34
Chrome commercial, bbl	lb.	12 - .12½
Paris, bulk	lb.	28 - .30
Reds, Carmine No. 40, tins	lb.	4.50 - 4 70
Oxide red, casks	lb.	10 - 14
Para toner, kegs	lb.	1 00 - 1 10
Vermilion English, bbl	lb.	1 30 - 1 32
Yellow, Chrome C P bbls	lb	.21 - 22
Ocher, French, casks	lb	02½ - 03

Waxes

Bayberry, bbl	lb	$0 30 - $0 32
Beeswax, crude, bags	lb	21½ - 22½
Beeswax, refined, light, bags	lb.	32 - 34
Beeswax, pure white, cases	lb.	40 - .41
Candelilla, bags	lb.	20½ - 21½
Carnauba, No 1, bags	lb	42 - 43
No 2, North Country, bags	lb.	23 - 23½
No 3, North Country, bags	lb.	18½ - 19
Japan, cases	lb.	15½ - .16
Montan, crude, bags	lb.	.04½ - .04½
Paraffine, crude, match, 105-110 m p	lb.	.04 - .04½
Crude, scale 124-126 m.p., bags	lb.	.02½ - 03
Ref., 118-120 m p, bags	lb.	.03 - 03½
Ref., 125 m p., bags	lb.	.03½ - 03½
Ref, 128-130 m p, bags.	lb.	.03½ - .03½
Ref., 133-135 m p, bags	lb.	04½ - .04½
Ref., 135-137 m p, bags	lb	.05½ - 05½
Stearic acid, sgle pressed, bags	lb.	12½ - .13
Double pressed, bags	lb.	.13½ - .13½
Triple pressed, bags	lb.	.14½ - .14½

Fertilizers

Ammonium sulphate, bulk, f.o.b works	100 lb.	$3 25 - $3 30
F.a.s double bags	100 lb	3 85 - 3 90
Blood, dried, bulk	unit	4 00 -
Bone, raw, 3 and 50, ground	ton	27 00 - 30.00
Fish scrap, dom., dried, wks.	unit	3 75 -
Nitrate of soda, bags	100 lb.	2 45 - 2.52½
Tankage, high grade, f o b. Chicago	unit	3.60 - 3 70
Phosphate rock, f o.b. mines, Florida pebble, 68-72%	ton	$4 00 - $4.50
Tennessee, 78-80%	ton	8 00 - 8.25
Potassium muriate, 80%, bags	ton	34 55 -
Potassium sulphate, bags basis 90%	ton	43 67 - ......
Double manure salt	ton	25 72 - ......

The following base prices per 100 lb. are for structural shapes 3 in. by 3 in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$3.29	$3 14
Soft steel bars	3.19	3.04
Soft steel bar shapes	3.19	3.04
Soft steel bands	3.29	3.19
Plates, ¼ to 1 in. thick	3.29	3.14

Industrial

Financial, Construction and Manufacturing News

Construction and Operation

Arkansas

RUDY—The Fort Smith Fertilizer Co., Fort Smith, Ark., has leased a local tract of land, comprising about 40 acres, as a site for the construction of a new phosphate-fertilizer manufacturing plant, estimated to cost close to $100,000, with machinery. It is purposed to develop an output of 1,000 tons per day.

SUMMIT—The Thompson Paint & Color Co. is completing the erection of the first unit of a new plant at Summit, near Yellville, and plans to commence production at an early date It will be devoted to paint, varnish and kindred manufacture. It is planned to make extensions at a later date.

EL DORADO—The Lion Oil & Refining Co. has tentative plans for the construction of an addition to its refinery for considerable increase in capacity. E. C. Winters is one of the heads of the company

California

ORO GRANDE—The Riverside Portland Cement Co., Riverside, Calif., has acquired the plant and property of the Golden State Portland Cement Co., Oro Grande, near Victorville, for a consideration said to be $1,500,000. The new owner has plans in progress to increase the capacity of the mill from 1,200 to 3 600 bbl. per day, with cost estimated at close to $500,000, including machinery.

SALINAS—E. M. Galli, Hollister, Calif., operating a local plant for the manufacture of concrete pipe and kindred products, has acquired property on Market St., Salinas, as a site for a new branch plant, for which plans will be prepared at an early date. Joseph Cassi is also interested in the company.

LOS ANGELES—The Pan-American Petroleum & Transport Co is perfecting plans for the construction of its proposed oil-refining plant on tract of land at Wilmington, in the harbor section, recently acquired The initial plant will be equipped for a capacity of 12,500 bbl. per day, and is estimated to cost in excess of $2,000,000, with machinery. A second plant unit of like size will be built at a later date. E. L. Doheny heads the company.

Florida

FORT PIERCE—The Non-Acid Fertilizer & Chemical Co. has tentative plans under consideration for the construction of a local plant for the manufacture of commercial fertilizer, estimated to cost close to $100,000 with machinery. E. D. Noe is one of the heads of the company.

Georgia

SAVANNAH—The Southern Cotton Oil Co. has preliminary plans for extensions and improvements at its local plant, estimated to cost close to $75,000, including equipment.

Illinois

CHICAGO—The Gutmann Tanning Co., 1511 Webster St., has filed plans for the erection of its proposed new tanning plant at 2128-40 Dominick St., 100x150 ft., estimated to cost $150,000, with equipment. The general contract has been let to J. Kalchbrenner, 133 West Washington St.

CICERO—The Barrett Co., 12 South La Salle St., Chicago, has completed plans and will soon commence the erection of a new side addition at its varnish-manufacturing plant at 16th St. and 51st Ave. H. A. Mulder, 140 South Dearborn St., Chicago is architect.

Indiana
